ARTS and SCIENCES.

ELOCUTION.

ELOCUTION is a term which, according to the ſtrictneſs of etymological definition, might be applied to ſignify every thing that is included in the faculty and utterance of thought, by the means of language, whether oral or written; and ſome writers, even in modern times, have applied it, with more attention apparently to derivation than to authorized preciſion and neceſſary contradiſtinction, to written compoſition as well as to actual ſpeech. At the ſame time, two other terms, oratory and eloquence, (which etymological refinement might undoubtedly reduce to the ſame original ſignification,) have admittance and current uſage in our language, and are occaſionally uſed as ſynonyms of elocution in our looſer converſation. But every copious ſubject, when it comes to be treated in a didactic way, requires more terms of ſettled diſtinction than the ſimplicity of rigid etymology can be expected to furniſh; and "many terms which, in the laxity of general converſation, are indifferently and indiſtinctly uſed, in the preciſion of ſcientific diſcuſſion muſt be carefully ſeparated and placed in contradiſtinction: the very admiſſion of ſynonyms being perfectly inconſiſtent with the progreſs and comprehenſion of ſcientific truth."

Theſe three terms, therefore, in the very outſet of the preſent ſubject, ſhould be clearly and diſtinctly defined, and the boundaries of ſignification aſſignable to each, as terms of contradiſtinction, be preciſely marked. This has accordingly been done by a popular lecturer of the preſent day. "Eloquence," ſays he, "may be defined, "the art of expreſſing our thoughts and feelings with preciſion, force, and elegance; and of heightening the impreſſions of reaſon by the colourings of imagination." It is applicable, therefore, to the whole faculty of verbal diſcourſe, whether oral or written. It addreſſes itſelf by the pen, to the eye, as well as by the living organs to the ear. Thus we ſpeak (with admitted accuracy) of an eloquent book, as freely as of an eloquent oration; of the eloquent Buffon (alluding to his celebrated work upon natural hiſtory); and of the eloquent writings, as well as the eloquent ſpeeches of Edmund Burke. The Apoſtrophe to the queen of France, is as genuine a piece of eloquence as if it had been ſpoken in the houſe of commons.

Oratory, on the contrary, is preciſe and limited in its application: and, in this reſpect, indeed, even popular uſage is pretty generally correct. It may be defined, "oral eloquence; or the art of communicating, by the immediate action of the vocal and expreſſive organs, to popular, or to ſelect aſſemblies, the dictates of our reaſon, or our will, and the workings of our paſſions, our feelings, and our imaginations." Oratory, therefore, includes the idea of eloquence: for no man can be an orator who hath not an affluence of thought and language. But eloquence does not neceſſarily include the idea of oratory; ſince a man may be rich in all the ſtores of language and of thought, without poſſeſſing the advantages of a graceful and impreſſive delivery. It is, therefore, the name of a more complex idea; and includes, beſides the general notion of eloquence, the practical part of elocution: which being our immediate object, muſt be ſpoken of more at large. "Elocution may be regarded either as a ſcience, or as an act. In the former caſe it may be defined, "the ſcience by which the rules for the juſt delivery of eloquence are taught;" in the latter, "the happy combination and coincidence of vocal, enunciative, and geſticulative expreſſion, by which oratorical excitement is ſuperadded to the eloquence of thought and language." In other words: "Elocution is the art, or the act of ſo delivering our own thoughts and ſentiments, or the thoughts and ſentiments of others, as not only to convey to thoſe around us (with preciſion, force, and harmony) the full

Strahan and Preſton,
New-ſtreet Square, London.

purport and meaning of the words and ſentences in which thoſe thoughts are clothed; but, alſo, to excite and impreſs upon their minds, the feelings, the imaginations, and the paſſions, by which thoſe thoughts are dictated, or with which they ſhould naturally be accompanied."

"Elocution, therefore, in its more ample and liberal ſignification, is not confined to the mere exerciſe of the organs of ſpeech. It embraces the whole theory and practice of the exterior demonſtration of the inward workings of the mind." In ſhort, "eloquence may be conſidered as the ſoul, or animating principle of diſcourſe; and is dependent on intellectual energy and intellectual attainments. Elocution is the embodying form, or repreſentative power; dependent on exterior accompliſhment, and cultivation of the organs. Oratory is the complicated and vital exiſtence reſulting from the perfect harmony and combination of the two."

The object, then, of the ſcience of elocution is the improvement of oral language, as contradiſtinguiſhed from mere graphic compoſition; and the cultivation of every external grace and accompliſhment with which the delivery of language ſhould be accompanied, whether in reading, in recitation, or in ſpontaneous utterance: an object, to the attainment of which the ancients devoted a very conſiderable portion of attention; and for the due comprehenſion of which, it appears to be neceſſary to go ſomewhat deeper in our reſearches into the phyſical and moral powers of man, than has been ſuſpected by the generality of modern profeſſors; and inſtead of calling in queſtion, as ſome recent cavillers have done, whether elocution is even to be regarded as an art, to eſtabliſh its doctrines on the ſettled principles of ſcience, and demonſtrate the eſſential elements of that ſcience as a branch of natural philoſophy. To the want of this due conſideration of the ſubject, and to the incongruous maxims relative to it, are perhaps to be attributed not only the frequency of every ſpecies of diſguſting impediment in modern ſpeech, but the lame and impotent ſtate of public ſpeaking among us, when compared in its effects with the ſplendid and impreſſive oratory of ancient times. "In thoſe parts of oratory, indeed, which relate to the arrangements of thought, and the energies of expreſſive language, there is no deficiency of exiſting models; and, certainly, no paucity whatever of pedantic rules and treatiſes. Cicero and Demoſthenes ſtill continue to ſpeak to the eye, in all the eloquence of graphic words; and Quintilian and Blair (like two conſpicuous luminaries, in the ancient and modern hemiſpheres of oratorical criticiſm) illumine the tracks of written language, and may help to inform us how orations ſhould be compoſed. In this part of oratory, the preſent and the preceding generation have, accordingly, ſomething to boaſt. But for the theory and practice of thoſe impreſſive exterior demonſtrations with which the delivery of ſuch orations ſhould be accompanied, to what ſyſtems, or to what models can the Engliſh ſtudent appeal? In ſhort, eloquence has been cultivated among us with conſiderable diligence; but elocution has been ſo much neglected, that the very nature of the ſcience ſeems to be entirely forgotten; and the few fragments of antiquity that have deſcended to us upon the ſubject, are evidently miſunderſtood by thoſe who have pretended to comment upon them; and many of our moſt learned critics have either ingenuouſly acknowledged, or unwarily betrayed, their total inability to comprehend ſome of thoſe very diſtinctions moſt indiſpenſable to the expreſſion and harmony of oratorical delivery: ſuch, for example, as the muſical accents of ſpeech, or inflections of the voice in the harmonic ſcale; the proportions of reſpondent ſounds and cadences, and the eſſential contradiſtinctions of percuſſion, accent, and quantity."

Such is the language of the lecturer already quoted; who, to reſcue the elements of elocution from this ſtate of neglect and chaos, and to facilitate the general attainment of an accompliſhment ſo generally deſirable, proceeds, in his "Introductory Diſcourſe," thus curſorily to ſtate the extent and nature of the ſubject.

"Elocution," ſays he, "is, 1. Partly a ſcience, founded on aſcertainable principles, and ſuſceptible of palpable demonſtrations; 2. Partly an art, attainable by imitative application and obſervance; and ſubject to ſuch laws as reſult from compariſon of general principles with practical experience; and, 3. Partly an object of taſte and ſentiment, dependent on acuteneſs of perception, and delicacy and refinement of feeling.

1. "As a ſcience its foundations are to be ſought, 1ſt. In phyſiology; that is to ſay, in the anatomical ſtructure of the elocutionary organs, and the laws of phyſical neceſſity, by which their actions and reactions are directed and circumſcribed: ſome knowledge of which ſeems to be indiſpenſably requiſite to the complete developement and exertion of their reſpective powers; to the ſupply of accidental and occaſional deficiencies; and to the correction of thoſe erroneous and defective modes of utterance, which, originating in negligent or vicious imitation, have ripened into habitual impediments. 2d. In muſic, the eſſential laws and accidents of which, with only one conſpicuous exception;" the progreſs of the tune, in one inſtance, being by ſlides or accentual inflections, "lifting the voice up and down in the muſical ſcale;" and in the other, by aſcertainable intervals and perceptible gradations; "are as applicable to elocution as to ſong: all fluent and harmonious ſpeech (even that of the moſt eaſy and familiar converſation) as neceſſarily and as abſolutely falling into the rythmical diviſion of muſical bars, and into the two generic meaſures of common and of triple time, as the warblings of the moſt ſcientific ſinger on the ſtage; while ſeveral of the impediments which moſt ſeriouſly obſtruct and deform the elocution of injudicious ſpeakers, may be proved to originate in no other cauſe than the violation of theſe muſical principles, and the conſequent reſiſtance of thoſe phyſical neceſſities which limit the facilities of organic action, and with which the elementary principles of harmonic proportion ſo admirably and ſo myſteriouſly conform. 3d. In philology, alſo, elocution hath a baſis, inaſmuch as to the philoſophy of the ſtructure and compoſition of language, and to the acute reſearches of the etymologiſt, many of thoſe diſputed queſtions of pronunciation, quantity, and percuſſive accent, which have hitherto been ſurrendered to the arbitrary and fluctuating deciſions of faſhion, ought, in reality, to be referred."

To which might have been added that the time of ſpeech itſelf, is, or ought to be, a reſult of philological perception: the quantities, emphaſes, and inflections of ſyllables, in all perfect ſpeech, being dictated by the ſenſe and import of ſuch ſyllables; either inherent in their original ſtructure and individual ſignification, or derivable from ſentiment and aſſociation.

2. As an art, the laws of elocution are partly grammatical, as ariſing out of the ſtructure and arrangement of ſentences, and the conſequent degrees of connection and relationſhip between the different words and members and portions of the diſcourſe to be pronounced; partly harmonic, as connected with the practical regulation of the variations and proportions of harmonic ſound, with which ſuch diſcourſe ſhould be accompanied; and partly mechanical, or experimental,

mental, as relating to the motions and poſitions of the reſpective organs, by which the varieties of vocal and enunciative expreſſion are produced.

3. As a matter of taſte, elocution embraces the conſideration of ſuch peculiar habits of ſtudy, deportment, and aſſociation, as are favourable to acuteneſs and delicacy of ſuſceptibility, both in the intellectual and the organic ſyſtem, and give them their peculiar bias and direction. In this point of view, all the finer arts, and all the more intellectual accompliſhments conſtitute eſſential parts of the ſtudies of the finiſhed elocutioniſt. He ſhould have an *eye* for the glowing tints and flowing lines of picture, the proportions of architecture and the ſymmetries of ſtatuary; an *ear* for the raviſhing delights of muſic; a *perception* of the vital graces of look and attitude and motion, far beyond all that the dancing ſchool and the opera houſe can teach; and a *ſoul* tremblingly alive to all the enthuſiaſm of poetry, and all the poignancy of ſentiment and pathos.

In vindication of the claim of this ſcience to ſuch an ample field of illuſtration and accompliſhment, an appeal may be made from modern maxims to the example of claſſical antiquity, to the facts that ſtand upon record, and the relics of ancient criticiſm that yet remain: for although much in the outſet of the inquiry appeared to the lecturer in the light of original diſcovery, further inveſtigation, we are informed, "convinced him, that many of thoſe doctrines, which he imagined to be new, are only "reſtitutions of decayed intelligence:" and what has, in reality, been added to the treaſures that well-directed labours might have redeemed from the overwhelmed ruins of claſſical criticiſm, is probably confined to the phyſiological parts of the ſubject, and the connection attempted to be traced between the primary laws of phyſical action and re-action, and the elements of muſical proportion."

Theſe, however, conſtitute a very eſſential portion of the ſcience of elocution; and the ſtudent of that ſcience muſt begin, in the firſt inſtance, by inveſtigating the ſtructure and offices of thoſe organs upon which the functions of ſpeech depend, which will be found to conſiſt of two diſtinct claſſes, the ſeparate actions and attributes of which, it is highly important that the profeſſor at leaſt ſhould accurately comprehend, leſt by miſtaking the ſource of the defects to be removed, he ſhould neceſſarily fail in the application of the remedy. Theſe are, 1, the vocal organs, or thoſe portions of the organic ſyſtem employed by the human (or other animated) being in the production and variation of expreſſive ſounds; and, 2, the enunciative organs, which, in the complication and perfection of their ſtructure, are peculiar to man, and are employed in ſuperadding to the ſounds of voice, certain other ſpecific impulſes, conſtituting thereby the elements and ſyllables out of which are compoſed the whole mechaniſm of human language.

When, however, theſe two claſſes of organs are ſaid to be diſtinct, that word is not to be underſtood in ſo abſolute a ſenſe, as to preclude the ſuppoſition of ſome of them diſcharging the two-fold office of modifying the tune and ſuperadding the ſpecific quality of literal element. The noſtrils, for example, which conſtitute a very eſſential part of the complicated organization that gives character to individual voices, are the chief implement employed in forming the elementary ſounds of *n*, *ng*, &c. while the teeth, and ſome other parts of the mouth, principally employed in the formation of the characteriſtic elements, have, alſo, a material operation in modifying the tone of the voice. The practical diſtinction is, however, ſufficiently evinced, by the ſeparate manifeſtation of their effects: the tones and inflexions of voice being exhibited in the moſt exquiſite perfection by ſeveral ſpecies of ſinging birds, who are deſtitute of the organization requiſite for ſpeech, and ſpeech itſelf being capable of proceeding, in the human ſubject, in forcible whiſpers, that is to ſay, by the action of the enunciative organs on a mere ſtream of breath, without accompaniment of any tone, or ſound of voice. Of this, however, more hereafter. See VOICE, ENUNCIATION, ORGANS of SPEECH, &c.

From the ſtructure of the organs, the phyſiological enquirer is next conducted to a conſideration of the laws of phyſical neceſſity, under which the functions of theſe reſpective organs are performed; and the mode of operation by which volition accommodates itſelf to the reſtrictions inevitably impoſed: an inveſtigation which involves ſeveral topics of conſiderable curioſity. From the ſimple principle of pendulation (the primary and indiſpenſible law of all reiterated action) are explained many of the eſſential phenomena of enunciative and vocal expreſſion, as the trill of the R; the impracticability of *reiterating* identical elements, or pronouncing, in immediate ſucceſſion, certain elements cloſely approximating in organic formation, without intervening pauſes; the facilities of certain combinations of element, the difficulty of others, and, conſequently, the phyſical cauſes of euphony and cacophony; (ſee EUPHONY, &c.) and, above all, the nature and cauſes of thoſe radical differences in the qualities of ſucceſſive ſyllables ſo well underſtood (in practice, and eſſence at leaſt, if not in cauſe,) by the grammarians of Greece, and deſignated by them under the terms *theſis* and *arſis*, but the total inapprehenſion of which has been the cauſe of ſo much confuſion in the theories and embarraſſment in the practical inſtructions of modern profeſſors. The leading dogmas of this ſyſtem are ſo ſelf-evident, their application to organic as well as mechanic motion, and to the actions of the organs of ſpeech in particular, ſo demonſtrable, and the coincidence of theſe actions with the phenomena of a certain alternate energy and remiſſion in the proceſs of verbal utterance ſo apparent, that it is only aſtoniſhing how the principle itſelf ſhould have remained ſo long obſcured. But there is ſtill room enough in the world of ſcientific diſcovery for other Columbuſes to crack the heavy end of other eggs. But our buſineſs is an abſtract, not a declamation. Thus then, it is contended, that action is of two kinds, continuous, or proceeding for a certain ſpace of time, in a certain direction, from one original impulſe, as the flight of a dart by the impulſe of the bow, or of a ball from the exploſion of a cannon, &c.; or reiterated and capable of unlimited continuity, from ſucceſſive impulſe, as in the pendulum of a clock, the motion of the legs in walking, &c. But ſpeech is not a continuous action proceeding for a certain ſpace in a certain direction from one original impulſe, like the flight of a dart, &c. but a ſeries of reiterated actions like thoſe of the pendulum, or of walking, &c. though much more complicated and diverſified by variety of phenomena, and, for that end, by neceſſary modification of impulſe. Still, however, ſpeech is action, reiterated action, reſulting from reiterated impulſe, and conſequently ſubject to the indiſpenſible law of reiteration, namely, re-action, or alternation; for as the pendulum when it has made its full ſwing in one direction muſt re-act in the oppoſite direction, before the primary action can be repeated; and as when one of the lower extremities has been advanced at full ſtride before the body it muſt either be drawn back again towards its former poſition, or, by a more complicated pendulation, the body muſt advance upon the limb, and thus reſtore the original poiſe to give the other extremity an opportunity of ſimilar action, before the leg firſt advanced can advance again; ſo when the tongue, lip, or uvula have acted in any given direction for the formation of any given element, it muſt re-act ſilently or expreſſively either upon the primary, or in ſome new direction, before the ſame element can be repeated, or any other element, requiring a ſimilar line of action can be formed. And ſo, alſo, when the primary organ of cadential or ſyllabic impulſe (the cartilage that ſurrounds the larynx) has been once contracted for the impulſion of the more energetic note, a re-action of that organ, either ſilent or accompanied by another note of leſs energy, muſt take place before the contractile energy can be renewed. Hence are derivable all the phenomena that belong to, or are to be deſcribed under the denominations of *cadence, meaſure, rythmus, metrical feet*, and other diſtinctions ariſing out of thoſe radical and eſſential differences in the qualities of ſyllables, ſometimes deſcribed by the terms *accented* and *unaccented*, and ſometimes by the very ſame writers, in the very ſame page, denied the diſtinction of accentuation; and ſometimes, alſo, confounded with the *quantities*, and by the denominations, of *long* and *ſhort*. but with which moſt certainly, neither accent nor quantity have any thing whatever to do. (See ACCENT, MEASURE, RYTHMUS, PROSODY, METRICAL FEET, QUANTITY, &c. See, alſo, POISE, THESIS, and ARSIS, PULSATION, and REMISSION, &c.) Hence, alſo, will be found derivable (not from caprice, or taſte, or arbitrary invention, but from phyſical principles) the diſtribution of all vocal melodies (and thence by imitation of all other melodies) into the proportions and cadences of common and of triple time; (ſee TIME,) and hence ſome light perhaps may be thrown upon that curious and hitherto unfathomable queſtion, the cauſe of the excluſive ſatisfaction received by the human ear from ſounds that follow each other in thoſe definite and ſimple proportions.

Having laid theſe foundations of theory on the ſolid baſis of experiment, the elocutionary phyſiologiſt may proceed to practice, and the crown and pinnacle of his labours conſiſt in the expoſition of the nature and cauſes of the various impediments and imperfections of ſpeech; and in the application of the proper remedies applicable to thoſe defects, whether originating in organic deficiencies, or malconformations; or adopted from imitation, confirmed by the inveteracy of erroneous habit. (See IMPEDIMENT.) The practical part of elocution alſo neceſſarily includes all that relates to the education and management of the organs of ſpeech; the improvement of the expreſſive powers of voice and enunciation; the laws of inflection, proportion and harmony; and the graces and accompliſhments with which the delivery of ſpeech (whether original or imitative) ſhould naturally be accompanied; and by which its effects upon the heart, the judgment and the imagination may be heightened and confirmed. See PHYSIOGNOMICAL EXPRESSION, GESTICULATION, &c.

Such is the general outline of the ſcience of elocution, according to the only profeſſor of modern times, by whom the ſubject has ever been treated in a ſcientific point of view, and from the notes of whoſe public lectures this abſtract is principally furniſhed; a ſcience which, however neglected, deſerves (for its practical application at once to the nobleſt purpoſes of public exertion, and the moſt familiar gratifications of private life,) a conſiderable portion of the attention of thoſe who are entruſted with the education of youth. For if oratorical excellence be an object only to the few, yet that thoſe few ſhould have the means of cultivating thoſe parts of ſuch excellence which appear to be within reach of ſyſtematic tuition, is certainly highly deſirable; and (not to dwell upon the conſideration that it is not always practicable to foreſee, during the ſeaſon of early tuition, who ſhall, or who ſhall not, be among the number of that few to whom ſuch accompliſhment might be of primary importance) "ſome degree, at leaſt, of elocutionary accompliſhment is certainly deſirable by all. There are few, indeed, to whom it would not be advantageous (at leaſt in point of mental gratification) to be able to read, with emphaſis and harmony, the fine paſſages of our poets, or the inſtructive and elegant compoſitions of our hiſtorians, moraliſts, and amuſive writers:—There is, perhaps, ſcarcely any individual who has not, occaſionally, experienced the advantage of delivering what he had to ſay with correctneſs, eaſe, and impreſſiveneſs; or (lacking this accompliſhment) who has not felt the diſadvantages reſulting from ſuch defect. Even in the ſocial intercourſes of private life, how great are the benefits of this attainment! How does it multiply the ſources of innocent pleaſure! What a zeſt does it impart to the higheſt, though moſt familiar, of our intellectual gratifications!"

"Fortunately for mankind," continues Mr. Thelwall, "this accompliſhment, ſo univerſally to be deſired, needs never to be deſired in vain. With thoſe exceptions only, which reſult from deafneſs, or from mental imbecility, I ſhall, I think, demonſtrate, that (by no greater ſacrifice of time and effort than is uſually devoted to leſs important ſciences and much more frivolous accompliſhments) correct and impreſſive elocution is attainable by all." He admits, however, "that hitherto, at leaſt, the inſtances of ſuch attainment have been exceedingly rare; that few are the Engliſhmen who converſe with fluency and impreſſive grace; and fewer ſtill who can read with tolerable harmony and propriety. Even in our churches, the ſublimeſt paſſages loſe their impreſſiveneſs from the imperfect manner in which they are delivered; and thoſe very preachers who are moſt accompliſhed in every other particular, too frequently obſcure, by the wretchedneſs of their elocution, the eloquent diſcourſes they compoſe.

"But the cauſes of this it is not difficult to diſcover. We trace them, at once, in the almoſt univerſal neglect of this important branch of education. Even of the profeſſed teachers, in this department, where is the individual who has properly explored the extent, or the principles of the ſcience, or who has even ſuſpected that ſcience had any thing to do with the ſubject? It has almoſt been queſtioned whether elocution were even an art? Excellence has been regarded as the mere myſterious gift of nature or of fortune—as the original and unſolicited diſpenſation of a partial providence; which no education could ſecure, and which ſtudy and application were ſcarcely neceſſary to improve. With reſpect to the conſtituents of that excellence, mere taſte and preſentiment have been regarded as the only arbiters; the very laws of inflection and poportion have been denied all foundation and exiſtence in the utterance of modern ſpeech; and pronunciation, tone, and melody, and even the conſtituent requiſite of percuſſive accent, (upon which the individuality, the character and the force of ſpoken words eſſentially depend,) have been abandoned to the lawleſs rule of faſhion and caprice." Introductory Diſcourſe on the Nature and Objects of Elocutionary Science.

Elocution has by many been conſidered as contradiſtinguiſhable into three ſeveral kinds, reading, recitation, and ſpontaneous ſpeech; and ſome profeſſors have marked theſe diſtinctions ſo abſolutely, as to preſcribe different ſtyles of utterance, both in vocal and enunciative expreſſion, to the reader and the reciter, from thoſe which they regard as belonging to the unpremeditative ſpeaker. Mr. Cockin, in particular, in an ingenious diſſertation (publiſhed without his name, 1775) on "The Art of Delivering written Language," has maintained this hypotheſis; and has diſcuſſed the ſubject of theſe ſuppoſed differences under the reſpective heads of accent, emphaſis, modulation, expreſſion, (of voice as well as geſture,) and pauſes; for the latter four of which, ſee hereafter under their reſpective titles. This work, we are informed in the dedication, was altogether approved by Mr. Garrick, who aſſured the author "that the doctrine laid down in that eſſay agreed exactly with his own ſentiments." The popular axiom, however, "read exactly as you would ſpeak," (ſuppoſing it addreſſed to a good ſpeaker,) ſeems, in its principle, to be a rule much more rational than any thing that even the ingenuity of Mr. Cockin, though applauded by Mr. Garrick, has been able to adduce. It is objectionable, indeed, on account of its impracticability; pointing out a degree of perfection that was never yet attained, nor ever will be, till perfection in other arts and accompliſhments ſhall be attained alſo. But the principle is not, therefore, the leſs valuable; the models of perfection muſt not be diſcarded from our minds, becauſe art could never yet completely realize them: and although there are impediments, perhaps inſurmountable, in the way of giving either to reading or recitation all the eaſe, the grace, and the vitality of ſpontaneous ſpeech, yet, in principle, they ſhould aſſuredly be the ſame; for reading and recitation are only two different modes of imitating that nature, which ſpontaneous ſpeaking exhibits in her original reality; and the imitation ought to be ſo much the more perfect and exact, as, in this inſtance, the artiſt has the excluſive advantage of operating not only on the model, but with the very materials which nature herſelf employs in her creations. Mr. C., however, contends, "that reading does not receive any of its beauties from the principles of imitation, being no copy, but only another kind of ſpeech." That, generally ſpeaking, it is ſo, cannot be denied: but it is ſo far from unqueſtionable that it ought to be ſo, that this may be perhaps aſſigned as the genuine reaſon why the *reading* even of thoſe very perſons produces only ſleep, whoſe unpremeditated *ſpeaking*, is the delight of all ears; and why lectures never intereſt the auditors, like ſpontaneous harangues.

There are, however, certain particulars of eſſential diſtinction in the practical facilities, and even capabilities of excellence, in reading, recitation, and original ſpeech, which the ſtudent of elocution ought to underſtand, as thereby each may perhaps be brought ſomewhat nearer to perfection than can be expected without the due conſideration of theſe circumſtances. Thus, for example, ſpontaneous ſpeech, ſpringing immediately from the inſpiration of feeling, with all the freſhneſs and glow of original conception, is capable of a degree of warmth, eaſe, and flowing energy, which can belong only to firſt impreſſions and unpremeditated language. From this very circumſtance, however, it is incapable of all the ſmoothneſs, proportion, and harmony, which a minute attention to euphony, conſtruction, rythmus, and quantity, may enable the reader and reciter to accompliſh. The reader, on the contrary, who finds the language ready poliſhed to his hands, and ſees it ſpread out before him, has leiſure for full attention to all the minutiæ of rythmical cadence; and if his ear be good, his perceptions acute, and his notions of the principles of elocutionary harmony correct, he may certainly attain a degree of perfection of utterance, in what relates to mere proportion and melody, which none but the reader muſt expect. But then, on the other hand, the reader (eſpecially he who reads at ſight; and if he has previouſly ſtudied, he becomes, in a certain degree, a *reciter*,) pronounces what he reads, not with the feelings of an originator, or imparter, but with the feelings of a recipient; his mind is paſſive while his organs only are active: hence, inevitably, a certain degree of coldneſs and unnatural reſtraint. The reciter partakes of the advantages and diſadvantages of both; and he has both advantages and diſadvantages peculiar to himſelf. If what he ſhould repeat be completely in his memory, he makes it, to a certain degree, his own, and may *approximate* to the eaſe of the ſpontaneous ſpeaker, and the ſmooth melody of the accompliſhed reader, though he can never completely attain the unſophiſticated warmth and vitality of the former, or the complete rythmus and nicely meaſured pauſes of the latter. At the ſame time, by repeated experiment, he may have adjuſted his tones and attitudes, and the expreſſions of his countenance, more completely to the ſentiment and paſſion of the paſſages he is to deliver than the reader could poſſibly have done, and have accommodated them more completely to the rules and principles of grace, than is practicable to the ſpontaneous ſpeaker: but what he gains in force and propriety he is in danger of loſing in ſimplicity; and the mere reciter, however excellent, is more likely to extort applauſe than to awaken the genuine ſympathies of the ſoul. From this view of the ſubject, the lecturer already cited concludes, that though the principles of Engliſh elocution, fundamentally conſidered, are the ſame, to which ſoever of theſe three modes of utterance they may be applied, yet the practical excellencies and obvious difficulties of each being peculiar, the ſtudent of elocution, whatever department be his ultimate object, ſhould practiſe in all three, ſince reader, reciter, and ſpontaneous ſpeaker, have each ſomething to learn, from the other two, for the full accompliſhment of his own particular branch of the art.

Another and more rational diviſion of the art of elocution may be made from a conſideration of the ſubjects to which it is applied, or the circumſtances under which it is exerciſed. According to this principle, elocution may be conſidered as diſtinguiſhable into the following kinds, 1. The converſational; 2. The narrative; 3. The didactic; 4. The authoritative or judicial; 5. The argumentative; 6. The perſuaſive; 7. The declamatory and impaſſioned; relative to each of which ſome general rules may be laid down both with reſpect to voice and enunciation: as that in the firſt, the enunciation ſhould be eaſy and familiar, the tone ſimple, the inflection limited, and the pitch of the voice but juſt ſo far beyond a whiſper as to render it tuneable. In the ſecond, the enunciation, though exceedingly ſimple, ſhould be ſomewhat more preciſe and emphatic; the tone clear, unoſtentatious, and impreſſive; level, but not monotonous. In the third, both tone and enunciation ſhould be ſtrong, firm, and emphatic; which in the authoritative and judicial ſhould ſwell to ſomething like pomp, mingled with a degree of firmneſs that in effect ſhould border on auſterity, and with reſpect to modulation, almoſt on monotony. In the argumentative, clearneſs of voice and perſpicuity of enunciation are the principal objects. In the perſuaſive, the tones ſhould be mild, inſinuative, and pathetic, the pronunciation remote alike from the affectation of ſonorouſneſs and of preciſion. In this, indeed, as in the ſeventh and laſt deſcription of elocution, the enunciation ſhould rather be ſubſervient to the tone, (that is to ſay, to the feelings,) than the tone to the enunciation, as the object of the ſpeaker is rather to be underſtood by the heart than by the underſtanding. In ſubjects and paſſages of ſtrong paſſion and emotion, the enunciation ſhould be occaſionally accelerated and retarded; apparently wild and irregular, but obedient always to the changes of paſſion and ſentiment; the modulation extenſively varied, and the voice ranging through great varieties of ſoftneſs, force, and vehemence, of acuteneſs and gravity, and the whole compaſs of expreſſive or reflective intonation.

The four great ſchools of elocution, or rather the four great theatres for the exhibition of that talent, are, the bar, the pulpit, the ſenate, and the ſtage; and before we take leave of the ſubject, ſomething ought to be ſaid on each of theſe. We ſhall conſider them, therefore, in their alphabetic order.

Elocution of the Bar.—The ſtyle of elocution adapted to this profeſſion, will beſt be underſtood by conſidering the objects to which the eloquence of the bar is principally to be directed. Theſe are, 1. To demonſtrate, by the elucidation of evidence, diſputed facts; 2. To convince, by arguments, the doubtful judgment; 3. To influence by perſuaſion, or controul by declamation, the paſſions, the ſympathies and moral feelings of thoſe upon whom the deciſion of a cauſe may depend. For the firſt of theſe, we require an elocution diſtinguiſhed by impreſſive diſtinctneſs, an unaffected deliberation, and collected coolneſs; an enunciation preciſe without formality, at once terſe and familiar; a deportment candid, firm, and unaſſuming. For the ſecond, we demand an emphatic perſpicuity; an air of deciſive, but modeſt confidence; an ardour not impetuous, but chaſtened and reſtrained, by all the decorums of circumſtance and ſituation. For the laſt, the nobleſt, and moſt arduous of all the exertions of forenſic eloquence, are required, a range of elocutionary expreſſion, as various as the paſſions and emotions to be commanded; an inſinuating mildneſs, a melting or a kindling pathos; the tone, the look, the whole manner, geſticulation and deportment, ſhould occaſionally aſſume the entire range of expreſſive variety, from the moſt conciliating ſympathy to the deepeſt ſolemnity, and even, perhaps, on ſome occaſions to intimidating boldneſs. The occaſions, indeed, on which all that is here demanded can with propriety be exerted by the forenſic orator, may but rarely occur; but when they do occur, the opportunities are deciſive, and the reputation of the pleader, who is fully qualified to avail himſelf of them, is ſtamped for ever.

Elocution of the Pulpit.—The objects of clerical eloquence have been oratorically thus enumerated, "to inform the underſtanding even of the inapprehenſive; to arouſe the ſlumbering conſcience; to regulate the moral feelings; to reſtore the ſocial ſympathies, which the diſparities of fortune have but too much tendency to ſuſpend; to reſtrain the fury of ambition, and check the mad career of voluptuous prodigality; to unlock the iron graſp of avarice, and expand the liberal palm to deeds of charity; to humble the towering inſolence of pride, and diſarm the uplifted hand of oppreſſion and revenge; to infuſe the ſpirit of benevolence into the heart of unfeeling obduracy; to breathe the ſacred love of peace into the boſoms of the turbulent, and the mild ſpirit of forbearance and toleration into the ſoul of perſecuting bigotry and prejudice." How far all theſe objects are, practically, in the contemplation of every orator of the pulpit, this is no place to diſcuſs; but if ſuch be, in reality, among the proper objects of pulpit eloquence, it is obvious that all, and more than all, that we have demanded for the elocution of the bar, is requiſite in this ſpecies of elocution alſo. Among the indiſpenſible requiſites of ſuch elocution, are a familiar ſimplicity, inſinuative and endearing; an impreſſive energy, ſtimulative and arouſing; a pathos varied, characteriſtic, and deſcriptive; and a ſublimity awful, elevating, and commanding. A mingled ſolemnity and enthuſiaſm ſhould occaſionally give an air of inſpiration to the preacher, and his pronunciation, and all the particulars of utterance properly included in the term enunciation, ſhould be full, ſonorous, and oratorical, rather than looſe and colloquial. At the ſame time, nothing is more to be avoided than any overmarked peculiarity or affectation, or than the vulgar vehemence, the bawling and vociferation, which are ſometimes miſtaken for energy and oratorical animation.

The modes of elocution in this profeſſion, are thoſe of reading, as applied to portions of the ſcriptures, or to ſet forms of worſhip; of ſermon, which may be either read, (according to the general cuſtom of the church of England,) recited, (as is uſual among the preachers of the church of Scotland,) or delivered ſpontaneouſly, (that is to ſay, from notes or reflections previouſly digeſted, without actual compoſition,) as has been recommended by biſhop Burnet, and as is practiſed by ſome of our ſeparatiſts, and even by a very ſmall number of our regular clergy; and of prayer. Of the firſt of theſe, it is only neceſſary to ſay, that the only circumſtance in which it ſhould differ from any other ſpecies of reading, ſeems to be, that it ſhould be rather more ſolemn, and deliberate, from reſpect to the place and the occaſion to which it is accommodated. In all kinds of reading, the ſtyle of elocution ſhould accord with the ſubject, the tone and manner ſhould harmonize with the language and ſentiment; and as the ſubjects of ſcriptural and devotional reading are ſo exceedingly diverſified, it follows as a conſequence, that the ſtyle of the reader ſhould be diverſified as widely; and that nothing can be more inconſiſtent with the objects of clerical elocution than monotony. With reſpect to the three modes of delivering a ſermon, this is not the place for diſcuſſing their reſpective claims of preference; and what has been already ſaid of the application of the ſame common principles to reading, recitation, and ſpontaneous ſpeech, and the different kinds of excellence moſt attainable in each, precludes the neceſſity of particular rules for them reſpectively. In prayer, a ſolemn proſtration of manner, with a conſiderable mixture of enthuſiaſm, ſeems particularly required; and an eſpecial avoidance of all thoſe odd tricks and peculiarities, into which miniſters are ſo apt to fall. But the further conſideration of this ſubject belongs, properly, to the title GESTURE.

Elocution of the Senate.—As the eloquence of the ſenate is partly deliberative, partly controverſial, and partly declamatory, it requires an elocution uniting almoſt all the principal requiſites enumerated under the two preceding heads; and it admits, and even occaſionally demands, a more impetuous warmth, a more rapid and vehement emotion, than in either of the former inſtances could be at all decorous. The ſermons of Maſſillon might require, or, at leaſt, their effect might be heightened by a denunciative ſeverity, an awful auſterity of manner, that ſhould impreſs his audience with all the ideas and feelings of a ſupernatural agency; and under ſuch circumſtances the oratory of the pulpit might ſeem to have been carried, even above the heights, and beyond the force of ſenatorial and popular oratory; but it is in the ſenate alone, and the popular aſſemblies of the nation, that the orator is to hurry away the impetuous paſſions, and tranſport the hearer into abſolute action; and there only are, of courſe, required the full thunders of elocutionary energy. But it is not only in the fervid tones of an impetuous declamation, that the ſenatorial elocutioniſt ſhould excel; in the calm dignity of a well modulated cadence, and the poliſhed grace and propriety of enunciation, he ſhould alſo ſurpaſs; and in the eaſy urbanity of tone and euphony (when the ſtronger exertions of eloquence are not required) he ſhould manifeſt, at once, the dignity of the ſtateſman, and the elegance and refinement of the polite ſcholar. How little theſe circumſtances, (almoſt all of them within the reach of a well directed education,) are attended to, is but too generally known; and in the humble ſtate of modern oratory (as judged by its effects) the conſequences may but too well be diſcovered.

Elocution of the Stage.—The critical object of theatrical repreſentation is *imitation*. Its excellence is *veriſimilitude*. It is a moving picture, that exhibits ſounds as well as objects,

jects, and a part of whoſe pigments are the tones of the human voice. Its elocution, therefore, ſhould be that of Nature—Nature in her higheſt perfection. Ideal nature, if you pleaſe; ſuperior, in perfection, to any thing that individual nature ever exhibited, but in principle nothing deviating from unſophiſticated reality. The harmony may be more perfect, the intonation ſomething more diverſified, the inflection and range of the voice rather more extenſive, the utterance a little more emphatic, and ſome other graces and obſervances may be carried a degree further than ever was obſervable (or perhaps practicable) in ſpontaneous ſpeech and real life; but ſtill that ſpontaneity and reality muſt be the models; and the elocution, in all eſſential particulars, that would be unfit for the bar, the pulpit, or the popular aſſembly (ſo far as the difference does not ariſe out of the different ſentiments to be expreſſed and paſſions to be indulged or excited) is unfit for the ſtage alſo. It ſhould be remembered, however, that the drama deals in the *extremes* of paſſion and emotion; that its moral requires that it ſhould exhibit thoſe paſſions burſting all bonds of decorum, and triumphing over the reſtraints of reaſon. The player has frequently to exhibit the judgment under the domination of paſſions; and is even to repreſent the full malignity of the worſt, as well as the imprudent exceſſes of the beſt paſſions of our nature; while the paſſions of the orator are always, in reality, (though not always in appearance,) to be under the controul of his judgment; and all the malignant and evil paſſions are to be ſuppreſſed, or kept out of ſight, any otherwiſe than as they may be *mentioned*, or alluded to, in moral reprehenſion. Hence even the ſimplicity and truth of principle may, and muſt produce, occaſionally, much apparent difference of effect; and the ſame exerciſe of judgment (for the judgment of the player muſt, in reality, ſtill be paramount over his paſſion, though he be exhibiting the very reverſe) that leads the orator, to temper and qualify, may induce the actor, to exaggerate the paſſion. It is in theſe exaggerations, however, that the art and maſtery of the performer are moſt ſeverely tried, and taſte and judgment are alike imperiouſly requiſite. They are neceſſary undoubtedly to the perfection of his art; yet the inſtant the exaggeration is apparent, diſguſt begins;—the inſtant the vulgar feeling of wonder is excited, the tragedian ſinks to a level with the rope dancer; and many a time ought he to be overwhelmed with confuſion, by thoſe very plaudits to the attainment of which he has ſacrificed all the finer touches of nature that might have ſecured the genuine applauſe of ſympathy and emotion. But fully to attain, or even diſtinctly to comprehend, the higher excellencies of theatrical elocution, requires a very different courſe of preparation and ſtudy from what generally falls to the deſtiny, or enters into the apprehenſions of the profeſſors of this art. It is not in the ſcience of the green room, the library of the prompter, and the technical knowledge of ſtage trick, to make a finiſhed actor. To deliver language well, it is neceſſary fully to comprehend it, not looſely and colloquially merely, but grammatically, etymologically, and ſympathetically; to detect the niceſt ſhades of alluſion and diſcrimination, and enter into the ſentiment of the author; to realize the paſſion, where paſſion is, and the character, where the compoſition is characteriſtic. To excel in any ſpecies of elocution, therefore, demands ſome knowledge of general literature; to be a maſter of that elocution that ſhould illuſtrate the fine paſſages of Shakeſpeare, will require a knowledge of our language which, fully poſſeſſed, would entitle the elocutioniſt to the rare and valuable character of an *Engliſh ſcholar*. But the ſources of human paſſion muſt be ſtudied alſo; human nature muſt be known, in the general, and in the particular, in all ranks and conditions, and under all circumſtances and aſſociations. The perceptions muſt be diligently cultivated; the diſcriminative powers muſt be well exerciſed; feeling, keen, vigorous, varied feeling, muſt be cheriſhed; and the imagination muſt be perpetually at work. For the developement of the flexible powers of the voice, no pains well directed can be too elaborate, and the mind ſhould comprehend, and the ear ſhould perceive the delicacies and varieties of rythmus, with all the ſubtile nicety of a poet. The actor ſo qualified will diſcard from his elocution all the pedantries alike of the convent and of the green room; all profeſſional affections and preſcriptive peculiarities; he will copy nature in ſuch a ſtyle, that nature in her turn will copy him; and like the great actors of Greece and Rome, he will be worthy to give, while he receives, inſtructions to another Cicero or Demoſthenes.

ELODES, in *Botany*, Adanſon 444. (Elodea; Juſſ. 255.) A genus formed by Adanſon of the *Hypericum Ægyptiacum* of Linnæus, on account of an oblong ſcale or appendage to the claw of each petal, conſidered by Linnæus as a ſort of nectary, to which opinion he was probably led by the analogy of the nectariferous glands in his own *Hypericum Elodes*. We ſee no reaſon to ſeparate the above plant from *Hypericum*, nor does Juſſieu more than hint at the meaſure. See Hypericum.

Elodes is alſo uſed among the ancient writers in *Medicine*, for a ſpecies of fever, attended with profuſe ſweats.

ELOGIUM, Eloge, a praiſe, or panegyric, beſtowed on any perſon or thing, in conſideration of its merit.

The word is Latin, but formed of the Greek ευλογια, *commendation*; which is compounded of ευ, *well*, and λεγω, *to ſay*, or *ſpeak*.

The ſecretary of the Royal Academy of Sciences at Paris formerly compoſed the eloges of ſuch members as died; and delivered them at the next public meeting of the company. Funeral orations are eloges of eminent perſons deceaſed.

Extravagant and improbable eloges are of the greateſt diſ-ſervice to their own deſign; and do, in effect, diminiſh the perſon whom they pretend to magnify, and degrade him whom they profeſs to exalt. Any worthy man may paſs through the world, unqueſtioned and ſafe, with a moderate recommendation: but when he is ſet off and bedaubed with rhetoric, and embroidered ſo thick, that you cannot diſcern the ground, it awakens naturally (and not altogether unjuſtly) intereſt, curioſity, and envy; for all men pretend a ſhare in reputation, and love not to ſee it engroſſed, or monopolized; and are therefore apt to enquire (as of great eſtates ſuddenly got) whether the perſon ſo commended, came honeſtly by it, and of what credit the perſon is that tells the ſtory.

ELOHA, in *Scripture*, the ſingular of Elohi, one of the names of God. See Elohi.

ELOHI, Eloi, or Elohim, one of the names of God. But it is to be obſerved, that angels, princes, great men, judges, and even falſe gods, are ſometimes called by this name. The connection of the diſcourſe aſſiſts us in judging rightly concerning the true meaning of this word. It is the ſame as Eloha; one is the ſingular, the other the plural. Nevertheleſs, Elohim is often conſtrued in the ſingular number, particularly when the true God is ſpoken of; but when falſe gods are ſpoken of, it is conſtrued rather in the plural. Calmet, Diction. Bibl. See Jehovah.

ELOI. See Elohi.

ELOIGNED, in *Law*. See Eloncata and Elongatus.

ELOINE, ſignifies to remove, or ſend a great way off. Thus it is ſaid, if ſuch as be within age be eloined, ſo that they cannot come to ſue perſonally, their next friends ſhall be admitted to ſue for them. Stat. 13 Ed. I. cap. 15.

ELOME, a name given by ſome authors to orpiment.

ELON, in *Ancient Geography*, a town of Paleſtine, in the tribe of Dan. Joſh. xix. 43.

ELONGATA, in *Law*, is a return of the ſheriff, that cattle are not to be found, or removed, ſo that he cannot make deliverance in replevin. 2 Lil. Abr. 454. 458.

ELONGATION, in *Aſtronomy*. The angle under which we ſee the diſtance of a planet from the ſun, reduced to the ecliptic.

Let S T (*Plate* XII. *Aſtronomy*, *fig.* 104.) be the diſtance of the ſun from the earth, S L the curtate diſtance of the planet from the ſun, the angle T S L equal to the difference of longitude of the planet P and earth T ſeen from the ſun, called the commutation; the reſolution of the triangle T S L, in which the two ſides and contained angle are given, will give the angle at the earth S T L, called the elongation, and this being taken from the longitude of the ſun, if the planet is to the eaſt, or right of the ſun, will give the geocentric longitude of the planet.

The triangle S L T may be reſolved by the following rule: the leaſt ſide is to the greateſt as radius is to the tangent of an angle, from which 45° muſt be taken. The tangent of the remainder, multiplied by the tangent of half the ſum of the unknown angles, gives the tangent of half their difference, which muſt be added to or ſubtracted from the half ſum to trace the angle of elongation. This angle is the leaſt of the unknown angles in the caſe of an inferior planet when the half difference muſt be ſubtracted; it is the greateſt for a ſuperior planet when it muſt be added.

It is ſometimes uſeful to recollect the following proportions.

The ſine of the commutation is to the ſine of the elongation as the tangent of the heliocentric latitude is to the tangent of the geocentric latitude.

The ſine of the elongation is to the ſine of the commutation as the curtate diſtance of the planet from the ſun is to the curtate diſtance of the planet from the earth.

It is at the time of the greateſt elongations of the inferior planets Mercury and Venus, that they are uſually ſeen to the greateſt advantage. The greateſt elongation of Venus was, according to Ptolemy, from 45° 25″ to 47° 35′, and that of Mercury between 16° 8′ and 28° 37′. According to our modern tables theſe numbers are, for Venus 44° 57′ to 47° 48′, and for Mercury 17° 36′ to 28° 20′.

ELONGATION is alſo uſed, by ſome authors, for the difference in motion, between the ſwifteſt and the ſloweſt of two planets; or the quantity of ſpace, whereby the one has overgone the other; called alſo *ſuperation.*

The ſwifteſt motion of the moon, with regard to the ſun, is called the elongation of the moon from the ſun. We alſo ſay diurnal elongation, horary elongation, &c.

ELONGATION, as it relates to *Fortification*, is a term uſed to expreſs that deviation from the immediately regular conſtruction, which is derived from a polygon formed upon a circle, to one formed upon an ellipſis, or oval: when this happens, only two of the faces retain that conſtruction and proportion which would appertain to the reſpective circles of which they would each form a part. In this we conſider the ellipſis in queſtion to be drawn upon two circles, and having a line paſſing through both their centres, as well as through the centres of the two retained faces; which neceſſarily are parallel. The two ſides, or *elongated* arcs of the ellipſis, may be divided into any number of faces, according to the extent of the area incloſed; they are uſually on the ſcale of the *greater* ſyſtem, while the ends are on the ſcale of the mean ſyſtem. Sometimes the elongation muſt be made ſo as to occupy a great extent of front; in which caſe it may become expedient to throw forth a crown-work from the centre of the *elongated* arc, or line, in order to prevent the enemy from occupying any part of the eſplanade ſufficiently near to batter thoſe works which may be rather weak for want of a flanking fire ſufficiently powerful to impede the beſiegers. Theſe crown-works anſwer much the ſame purpoſe as advanced redoubts in front of a line of entrenchments, and ſcour the whole advance ſo completely, enfilading the aſſailants, as to render it peremptorily neceſſary to become maſters of them before the lines can be carried. This will ſhew not only their ability, but the abſolute neceſſity for conſtructing all ſuch advanced defences, in that ſcientific manner which may render them untenable by the enemy, after being poſſeſſed by them, as well as perfectly incompetent to make any impreſſion on the intrenchments, which would command them *in reverſe*, that is, in their rear, and compel the enemy to quit. Crown-works being on a more important ſcale, require that every attention ſhould be paid that their batteries ſhould not bear upon any of the main defences.

The foregoing relates to regular works: for the irregular we have ſcarcely any thing like a defined rule; but it muſt always be held in mind, that the more the defences are elongated, the more they will require additional ſupport, either from various lines of fortification one within the other, or from detached works, ſo ſituated as to defend the weaker parts. This neceſſity ariſes chiefly from the ſaliant angles being rarely allowed to fall within 90°, leſt they ſhould plunge upon ſome other parts of the defences; whereas in all works formed upon a pentagon, hexagon, heptagon, or even an octagon, the angles of the baſtions may be conſiderably reduced, and the ravelines equally ſo; it is owing to this that fortreſſes, on a large ſcale, not only admit, but require, numerous additional defences to fill up the ſeveral intervals between the exterior ſaliant angles, or extremes of the defences, but to prevent the enemy from occupying poſitions favourable to their views.

We do not term works conſtructed in an irregular manner along the ſhores of a bay, or around a peninſula, *elongated;* they may be carried for miles without coming under that deſignation; it is only when a line of defence, and particularly fortifications, forming a figure either perfectly regular, or nearly ſo, are in every particular part extended, for the purpoſe of embracing more ſpace, or conforming to any particular local circumſtance, that we conſider the term *elongation* to be applicable.

In *Tactics*, the term implies ſuch an extenſion of the front as is produced artificially, without the aid of reinforcements. Thus, we draw up troops only two, inſtead of three, deep, for the purpoſe of elongating our front; which conſequently thus becomes extended to half as much more as it formerly occupied in length. This is often neceſſary, but it certainly weakens the fire and the reſiſtance throughout; beſides, it prevents the caſualties in the front from being ſo readily filled up, and is apt to leave gaps, or openings, through which the enemy's cavalry may make a charge.

Where it is abſolutely neceſſary to retain a very firm front, yet to extend it ſo far as local means may allow, eſpecially where it is principally intended to repel the enemy's horſe, thoſe parts of the line which may be moſt expoſed by the evenneſs of the ground, &c. ought to be blocked by *abbatis*, that is, timber felled and laid in ſuch a manner as ſhould obſtruct the paſſage of cavalry; behind theſe a few men ſhould be diſperſed to prick off any of the aſſailants who ſhould attempt to cut an opening, or to drag away the trees, ſo as to obtain admiſſion. Frequently trees can be cut down, but cannot be drawn away to any choſen ſpot: in ſuch caſe, their trunks and principal branches may be left, while their leſſer boughs may be cut into ſtakes and paliſades for the defence of other parts. The line will of courſe be elongated by ſuch devices, while the more expoſed parts may retain their effective ſtrength. Where a convoy is in queſtion, and that the attack upon it can be made only upon one long front, which cannot be entirely covered by the waggons, &c. then, placing the artillery in the moſt commanding ſituations, the infantry muſt be ranged in ſuch manner as may *elongate* the defences, and keep the enemy in check. This will be peculiarly neceſſary where a neighbouring height muſt be cut off from the enemy's poſſeſſion, though it could not be occupied by the defenders of the convoy without weakening and dividing them.

The elongation of an attack, is where only a ſmall front is ſhewn at firſt, but is gradually extended ſo as to embrace a greater portion of the defences: thus, when after opening a battery upon a baſtion only, other batteries are made to bear upon the curtain almoſt parallel thereto; in ſuch caſe, we ſuppoſe only a bridge-head, or a *fleche* to exiſt, but no raveline. Likewiſe, when a column of infantry bearing down upon, and menacing only one particular point, ſuddenly deploys, and acts upon a greater extent of line, the attack is ſaid to be *elongated*. But, in either caſe, the term does not apply to any additional force brought to act on the ſame point; it relates to extenſion merely.

ELONGATION, in *Surgery*, is an imperfect luxation; when the ligament of any joint is ſo extended, or relaxed, as to lengthen the limb, but yet not to let the bone go quite out of its place. See LUXATION.

ELONGATUS, ELOIGNED, a return of the ſheriff that a perſon is conveyed out of his juriſdiction. See writ *de* HOMINE REPLEGIANDO.

ELOPEMENT, in *Law*, is when a married woman, of her own accord, departs from her huſband, and dwells with an adulterer; for which, without voluntary reconcilement to the huſband, ſhe ſhall loſe her dowry; nor ſhall the huſband, in ſuch caſe, be compelled to allow her any alimony. Stat. Weſtm. 2. 13 Edw. I. c. 34. See DIVORCE and DOWER.

"Sponte virum mulier fugiens, & adultera facta,
Dote ſua careat, niſi ſponſo ſponte retracta."

The word is formed from the Belgic, *Ee*, matrimony, and *loopen*, to run away.

However, mere advertiſing a wife in the Gazette, or other public papers, is not a legal notice to perſons in general not to truſt her; though a perſonal notice given by the huſband to particular perſons is ſaid to be good. An action lies, and large damages are uſually given, againſt a perſon for carrying away, and detaining another man's wife. See FORCIBLE *Abduction* and RAVISHMENT.

ELOPS, in *Ichthyology*, a genus of abdominal fiſhes, the character of which, according to the Linnæan ſyſtem, conſiſts in having the head ſmooth; edges of the jaws and palate rough with teeth; gill-membrane with thirty rays, and armed on the outſide in the middle with five teeth.

The genus elops is defined by Bloch as having the gill-membrane furniſhed with more than thirty rays, (ſpecimens he examined exhibiting thirty-four,) and Boſc admits there ſhould not be leſs than thirty to conſtitute the genus. Bloch conſiders the bony ſhield or plate beneath the chin, and the dorſal fin being placed oppoſite the ventral, as eſſential characters of the genus.

The only ſpecies of this genus at preſent known is the Linnæan elops ſaurus; le lézard of the French writers. Perhaps the earlieſt deſcriber of this fiſh is ſir Hans Sloane, who, in the ſecond volume of his hiſtory of Jamaica, gives a figure and detailed deſcription. He ſpeaks of it under the name of ſaurus maximus, and acquaints us that it is called in Jamaica the ſein-fiſh, or ſea gally-waſp. "This fiſh (he obſerves) was about fourteen inches long, in the middle five inches round, and tapering to both ends; the mouth in both jaws had one row of ſmall ſharp teeth, and on the upper two more within, parallel to them, and a row of the ſame on the upper part of the cartilaginous tongue; three quarters of an inch from the end of the ſnout were the eyes, round, and grey; there were two *pinnæ poſt branchias*, two under the belly, one on the middle of the back, *poſt anum* another, and a forked tail; it was all over ſcaly, the back of a dark brown, and the belly of a white colour." The ſpecies is found in various parts of the American ſeas; it was met with by Dr. Garden about Carolina, and communicated by him to Linnæus. The ſtrong ſpine at each ſide of the tail is conſidered as a ſpecifical diſtinction of elops ſaurus by Linnæus, Gmelin, and others, but this muſt obviouſly remain a very doubtful character till another ſpecies at leaſt of the ſame genus be diſcovered in order to aſcertain whether ſuch ſpines be not characteriſtic of the genus inſtead of the ſpecies.

It has been obſerved by writers that elops ſaurus bears ſome reſemblance to a pike, or rather to a ſalmon; with the former it has no kind of affinity whatever, but on the contrary it is ſo cloſely allied to the ſalmo tribe that were it not from being deſtitute of the fleſhy rayleſs fin, ſo uniformly obſervable on the lower part of the back in the ſalmon kind, we ſhould be almoſt induced to refer it to that genus.

The head of elops ſaurus is without ſcales. The lower jaw rather longer than the upper. Both jaws, together with the tongue and palate, are armed with a vaſt number of ſmall teeth. The eyes nearly vertical; the irides double, the inner one yellow, exterior red, and the pupil black; and the eyes partly covered with the ſkin of the head. The body of this fiſh is ſlender, and the ſcales large; the head yellowiſh, back blueiſh, ſides ſilvery. The lateral line is ſtraight. All the fins browniſh; the exterior half of the pectoral fin, anterior part of the dorſal fin, and extremity of the tail blueiſh. The tail is much furcated, and divided in the middle by a diſtinct longitudinal ſtripe of black.

ELOPS, Ελωψ, in *Zoology*, the name of a ſerpent, otherwiſe called elaps.

ELOQUENCE, the art of ſpeaking or writing well, ſo as to move and perſuade. The term, however, in its greateſt latitude, denotes that art or talent, by which the diſcourſe is adapted to its end; "Dicere ſecundum virtutem orationis. Scientia bene dicendi." Quintilian. In common converſation, however, the word eloquence is ſeldom uſed in ſuch a comprehenſive ſenſe. But this definition exactly correſponds to Tully's idea of a perfect orator; "Optimus eſt orator qui dicendo animos audientium et docet, et delectat, et permovet." Accordingly all the ends of ſpeaking are reducible to four; every diſcourſe or ſpeech being intended to enlighten the underſtanding, to pleaſe the imagination, to move the paſſions, or to influence the will. When a ſpeaker addreſſes himſelf to the underſtanding his aim is to inform, and to convince, for the former of which purpoſes the predominant quality is perſpicuity, and for the attainment of the latter, argument. By the firſt we are made to know, and by the ſecond to believe. The imagination is addreſſed, by exhibiting to it a lively and beautiful repreſentation of a ſuitable object. As in this exhibition, the taſk of the orator may be ſaid to reſemble that of the painter, which conſiſts in imitation, the merit of the performance reſults entirely from the two following ſources, *viz.* dignity, as well in the ſubject, or thing imitated, as in the manner of imitation, and reſemblance, in the portrait or performance. This addreſs attains the ſummit of perfection in the *ſublime*, (which ſee,) or thoſe great and noble images, which, preſented to the mind in ſuitable colouring, expand, as it were, the imagination with ſome vaſt conception, and quite raviſh the ſoul. The characteriſtic of the third ſpecies of diſcourſe, or that which is addreſſed to the paſſions, is the *pathetic*. (See PASSIONS and PATHOS.) But the moſt complex and moſt important of all the kinds of eloquence is that which is calculated to influence the will and to perſuade to a certain courſe of conduct. This is an artful mixture, of that which propoſes to convince the judgment, and of that which intereſts the paſſions; and its diſtinguiſhing excellence reſults from theſe two, the argumentative and the pathetic duly blended. Theſe, combining their force and acting in concert, conſtitute that *vehemence* of addreſs, which is admirably fitted for perſuaſion, and has always been regarded as the ſupreme qualification in an orator. This animated reaſoning was by the Greek rhetoricians termed δεινότης, and from ſignifying the principal excellency in an orator was uſed at length to denote oratory itſelf. Hence, as vehemence and eloquence became ſynonymous, the latter, in conformity to this mode of thinking, was ſometimes defined "the art of perſuaſion." In order to perſuade, which, though not the only object of eloquence, is the moſt important and for many reaſons the moſt difficult, the moſt eſſential requiſites are ſolid argument, clear method, a character of probity appearing in the ſpeaker, joined with ſuch graces of ſtyle and utterance as ſhall command attention to what he ſays. Hearers who exerciſe their underſtanding cannot be perſuaded, without being convinced; but conviction and perſuaſion, though they are ſometimes confounded, ought to be diſtinguiſhed from each other. Conviction affects the underſtanding only; perſuaſion, the will and the practice. It is the buſineſs of the philoſopher to convince a perſon of the truth; but it is the buſineſs of the orator to perſuade him to act agreeably to it, by engaging the affections of the hearer. Conviction and perſuaſion ought always to accompany each other, but this is not univerſally the caſe; becauſe the inclinations do not regularly follow the dictates of the underſtanding. The inclination may revolt, though the underſtanding be ſatisfied; the paſſions may prevail againſt the judgment. Conviction, however, is one avenue to the inclination, or heart; and it is that which an orator ſhould firſt endeavour by his utmoſt efforts to gain; for no perſuaſion is likely to be ſtable, which is not founded on conviction. But in order to perſuade, the orator muſt do more than produce mere conviction; he muſt duly conſider the nature of man, and endeavour to act upon the different ſprings by which he is moved. He muſt addreſs himſelf to the paſſions; he muſt paint to the fancy, and touch the heart; and hence, beſides ſolid argument and clear method, all the conciliating and intereſting arts, both of compoſition and pronunciation, enter into the idea of eloquence.

"We may diſtinguiſh," ſays Dr. Blair, (Lectures, vol. ii.) "three kinds, or degrees, of eloquence. The firſt, and loweſt, is that which aims only at pleaſing the hearer. Such, generally, is the eloquence of panegyrics, inaugural orations, addreſſes to great men, and other harangues of this ſort. This ornamental ſort of compoſition is not altogether to be rejected. It may innocently amuſe and entertain the mind; and it may be mixed, at the ſame time, with very uſeful ſentiments. But it muſt be confeſſed, that where the ſpeaker has no farther aim than merely to ſhine and to pleaſe, there is great danger of art being ſtrained into oſtentation, and of the compoſition becoming tireſome and languid.

"A ſecond and a higher degree of eloquence is when the ſpeaker aims not merely to pleaſe, but alſo to inform, to inſtruct, to convince; when his art is exerted in removing prejudices againſt himſelf and his cauſe, in chuſing the moſt proper arguments, ſtating them with the greateſt force, arranging them in the beſt order, expreſſing and delivering them with propriety and beauty, and thereby diſpoſing us to paſs that judgment, or embrace that ſide of the cauſe, to which he ſeeks to bring us. Within this compaſs, chiefly, is employed the eloquence of the bar.

"But there is a third and ſtill higher degree of eloquence, wherein a greater power is exerted over the human mind; by which we are not only convinced, but are intereſted, agitated, and carried along with the ſpeaker; our paſſions are made to riſe together with his; we enter into all his emotions, we love, we deteſt, we reſent, according as he inſpires us; and are prompted to reſolve or to act, with vigour and warmth. Debate, in popular aſſemblies, opens the moſt illuſtrious field to this ſpecies of eloquence; and the pulpit alſo admits it." See farther on the different ſpecies of eloquence under the article ELOCUTION. For the hiſtory of eloquence, and an account of the moſt diſtinguiſhed orators; ſee ORATORY and ORATOR. Thoſe who diſtinguiſh between eloquence and rhetoric repreſent the latter as propoſing and explaining the theory, and the former as the practice of the art; but they are generally uſed indiſcriminately for each other. See ELOCUTION and RHETORIC. On the ſubject of this article, ſee Campbell's Philoſophy of Rhetoric, Blair's Lectures, vol.ii. and Cambray's Dialogues on Eloquence.

ELORA, or **ELLORA**, in *Geography*, a town of Hindooſtan, in the vicinity of Dowlatabad, famous for its numerous pagodas, moſt of which are cut out of the natural rock. M. Thevenot, who has particularly deſcribed them, ſays, that for two leagues together nothing is to be ſeen but pagodas, in which are ſome thouſands of figures. The ſculpture of them he does not much commend; and we may apprehend, ſays major Rennell, that they are of early Hindoo origin. It ſhould be recollected, that Deoghire, which ſtood in this neighbourhood, was the greateſt and richeſt principality in the Deccan; and that the fame of its riches incited Alla to attack it in 1293; and theſe elaborate monuments of ſuperſtition were probably, as Rennell ſuggeſts, the offspring of that abundant wealth, under a government purely Hindoo. Sir C. W. Malet has given a particular account of theſe wonderful excavations, illuſtrated with drawings, in the ſixth volume of the "Aſiatic Reſearches." As to their origin or date no inquiry which he had been able to make afforded him ſatisfaction. He has no doubt, however, that they are the works of people, whoſe religion and mythology were purely Hindoo; and he adds, that moſt of the excavations carry ſtrong marks of dedication to "Mahdew," as the preſiding deity. Nevertheleſs he ſuggeſts, that the moſt northerly caves of Ellora, occupied by naked ſitting and ſtanding figures, are the works of the "Sewras" or "Juttees," who by the Brahmens are eſteemed ſchiſmatics, and whoſe ſect, called "Srawuk," is very numerous in Guzerat. The tenets, obſervances, and habits of the "Sewras" are peculiar, and in many points very different from other Hindus. Their adoration of the deity is conveyed through the mediation of "Adnaut" and "Pariſnaut," the viſible objects of their worſhip, perſonified as a naked man ſitting or ſtanding. This ſect is ſuppoſed to be of a comparatively modern origin; and if this be the caſe, and the hypotheſis of the dedication of the temples to their idol be admitted, the limit of their poſſible antiquity will be aſſigned; but without aſcertaining, or affecting, that of the others. As to the antiquity of theſe aſtoniſhing works, this writer has detailed two different accounts; one given by an intelligent Mahometan and another by a Hindu. The account of the firſt is ſaid to have been derived from a perſon of acknowledged erudition. The ſecond was deduced from a book, entitled "Sewa Lye Mahat," or the grandeur of the manſion of Sewa, *i. e.* Mahdew. The Mahometan reported, that "the town of Ellora was built by rajah Eel, who alſo excavated the temples, and being pleaſed with them, formed the fortreſs of Deoghire (Dowlatabad,) which is a curious compound of excavation, ſcarping, and building, by which the mountains were converted into a fort, reſembling, as ſome ſay, the inſulated temple in the area of the "Indur Subba" (one of the pagodas.) Eel rajah was contemporary with Shah Momin Araf, who lived 900 years ago." The Brahmen, on the other hand, ſaid, "that the excavations of Ellora are 7894 years old, formed by Eeloo rajah, the ſon of Peſhpout of Elichpore, when 3000 years of the Dwarpa Youg were unaccompliſhed, which, added to 4894 of the preſent Kal Youg, makes 7894." Our author inclines to the former opinion. He farther informs us, that the "Koond," or ciſtern, mentioned by the Brahmens, is ſtill in excellent preſervation, juſt without the town of Ellora; and the holineſs of its water is even now in ſuch high eſtimation as to render it a "Teerut" (pilgrimage) of great reputation and reſort, under the appellation of "Sewalla Teeruit," or "Kond." There are many other excavations in a ſemicircular mountain, that commands a view of the fine valley of Ellora. In order to account for theſe extraordinary works, and the ſituation in which they were conſtructed, it ſhould be conſidered, that the ancient Brahmens avoided the contamination of cities, and affected the purity and ſimplicity of rural retirement. In ſituations remote from obſervation, the imagination of their diſciples probably enhanced the merits of their ſanctity. Accordingly, to alleviate auſterities, and to gratify the devout propenſities of theſe holy men, became objects of pious emulation. Under the influence of this principle, the munificence of princes may have engaged to provide them retreats, which, ſanctified by the ſymbols of their adoration, were at once ſuited, in ſimplicity and ſecluſion, to thoſe for whom they were intended, and in grandeur to the magnificence of their founders. Thus power and wealth may have been combined, under the guidance of enthuſiaſm, to produce monuments, ſcarcely leſs extraordinary or leſs permanent, though leſs conſpicuous and leſs known, than the pyramids of Egypt. Although ſome of theſe excavations are of very ancient origin, there are others, and particularly two, in a hill near a garden in the neighbourhood of Aurungabad, formed, as it is confidently aſſerted, by rajah Paur Sing, one of the Rajpoot Ameers of Aurungzebe's court, as a place of retirement, during his attendance on that monarch in his excurſions to the neighbouring garden.

ELOTZ, a town of Ruſſia, in the diſtrict of Orlof; 112 miles E.N.E. of Orel. N. lat. 53° 20'. E. long. 39° 14'.

ELOVKA, a town of Ruſſia, in the government of Tobolſk; 16 miles W. N. W. of Tomſk.

ELOY, Nicholas Francis Joseph, in *Biography*, was born at Mons, in the province of Hainault, on the 20th of September 1714, and died on the 10th of March 1788, having exerciſed his profeſſion as a phyſician with great ability and diſintereſted humanity. He was a man of extenſive learning, and great modeſty, and much addicted to ſtudy; whence, notwithſtanding his profeſſional avocations, he was enabled to write upon a variety of topics, and his publications are numerous. His firſt work, which was publiſhed in 1750, was a ſmall treatiſe, entitled "Reflexions ſur l'Uſage du Thé." His next publication was an attempt at a hiſtory of medicine, arranged in the form of a dictionary, and entitled "Eſſai du Dictionnaire Hiſtorique de la Medicine Ancienne et Moderne," in two volumes octavo, which appeared in the year 1755; this work was afterwards greatly enlarged, by extending the different articles which it contained, and was publiſhed in 1778, in four volumes quarto, with the title of "Dictionnaire Hiſtorique de la Medicine Ancienne et Moderne;" to which, as our readers will have obſerved, we have been much indebted for information relative to the different medical characters, of whom we have already given a biographical account. Eloy likewiſe publiſhed, in 1755, a ſmall volume, entitled "Cours Elementaire des Accouchemens;" and, a few years previous to his death, *viz.* in the years 1780 and 1781, he committed to the preſs two other eſſays, the firſt of which was entitled "Memoire ſur la Marche, la Nature, les Cauſes, et le Traitement de la Dyſenterie;" and the other, "Queſtion Medico-politique; ſi l'Uſage du café eſt avantageux à la ſanté, et s'il peut ſe concilier avec le bien de l'état dans les Provinces Belgiques?" As a ſlight reward for the patriotic zeal manifeſted in this tract, the eſtates of Hainault preſented him with a ſuperb ſnuff-box, with this inſcription, "Ex Dono Patriæ;" *the Gift of his Country*. He held the honourable office of phyſician to prince Charles of Lorraine. Nouveau Dict. Hiſtor. &c. Lyon, 1804.

ELPHIN, in *Geography*, a poſt town of the county of Roſcommon, province of Munſter, Ireland, 75 Iriſh miles W. by N. from Dublin, and 7 miles S. from Carrick, on Shannon.

Elphin, a biſhopric in Ireland, in the archi-epiſcopal province of Tuam. It dates its origin from St. Patrick, in the middle of the 5th century. It comprizes the greater part of the county of Roſcommon, a large ſcope in Sligo and Galway, and a very little in Mayo; and is reckoned one of the moſt valuable of the Iriſh biſhoprics. There are 75 pariſhes, which are formed into 29 benefices, and of theſe 26 have churches, which are the only ones in a tract of 420,150 Iriſh acres! The cathedral is a poor pariſh church, but the biſhop's palace is a very good modern houſe, in the midſt of an excellent demeſne, and adjoining the ſmall town of Elphin. Beaufort.

ELPHINSTON, William, in *Biography*, a Scotch prelate and ſtateſman, was born at Glaſgow about the year 1431. He was educated at the Univerſity of his native place, and became diſtinguiſhed for his proficiency in the learning of the times. He afterwards went to Paris, where he ſtudied the civil and canon law, and likewiſe delivered lectures with great reputation for ſeveral years. Upon his return to Scotland he was promoted to church livings, and admitted a member of the king's council. He was, ſoon after this, appointed a joint commiſſioner with the biſhop of Dunkeld and the earl of Buchan, in ſettling ſome diſputes between the courts of Scotland and France. As a reward for the prudence and eloquence which Mr. Elphinſton diſplayed on this occaſion, he was, on his return, nominated to the biſhopric of Roſs; whence, about the year 1484, he was tranſlated to the ſee of Aberdeen, and appointed, at the ſame time, to the chancellorſhip of the kingdom, an office which he held ſome time with the higheſt reputation; but when the troubles which took place between the king, James III., and his diſcontented nobility, had involved the kingdom in a civil war, he abandoned public ſtate affairs, and confined himſelf wholly to the duties of his biſhopric. But, on the acceſſion of James IV. his talents as a ſtateſman were again called into exerciſe, and from this time his ſovereign undertook no affairs of moment without his advice and concurrence. He died in 1514, at the advanced age of eighty-three, leaving behind him an excellent character; he was the patron of learning and learned men, and it is ſuppoſed, that by his influence the bull was obtained from the pope, for eſtabliſhing a univerſity at Aberdeen, with as ample privileges as were enjoyed by the moſt favoured ſeats of learning; and to his perſonal exertions and ſuperintendence, it was chiefly owing that the building of King's college was undertaken and completed. To that foundation he proved himſelf a munificent benefactor during the remainder of his life; and, at his death, when he bequeathed large ſums of money for its ſupport. Gen. Biog.

ELPISTICI, Ελπιςικοι, among the Greeks, a ſect of philoſophers, who made hope the ruling paſſion of mankind.

ELRICH, in *Geography*, a town of Germany, in the circle of Upper Saxony, and county of Klettenburg; formerly the capital of the county; in which are ſome conſiderable manufactures; 6 miles N. W. of Nordhauſen.

ELRICK, or EGELRIC ROAD, in *Antiquity*, was an ancient artificial road, made with great labour and expence through the fens, ten miles from Spalding to Deeping, by Egelric, abbot of Crowland, in the county of Lincoln, and afterwards biſhop of Durham; who, as Ingulphus relates in his hiſtory of that monaſtery, raiſed, by means of wood and gravel, a cauſeway, or cauſey, for travellers, through the centre of a wild foreſt and deep marſhes, called, after him, Egelric; or, by abbreviation, Elric-road. A part of it is ſtill viſible, lined with willows, between the river Welland, and the marſhes north of Crowland. Gough's Tranſlation of Ingulphus's Hiſtory of Crowland.

ELS, in *Geography*, a town of Moravia, in the circle of Brunn, 32 miles W. of Olmutz, and 24 N. N. W. of Brunn.

ELSA, a river of Tuſcany, which runs into the Arno, about a mile W. from Empoli.

ELSE, a river of Sileſia, which runs into the Oder, near Oderburg.

ELSEN, a ſmall town of France, in the department of the Roer, chief place of a canton in the diſtrict of Cologne, with a population of 304 individuals. But the canton contains 36 communes, and 12,239 inhabitants.

ELSEN, a town of Germany, in the kingdom of Weſtphalia, and biſhopric of Paderborn; 2 miles W. N. W. of Paderborn.

ELSFLETH, a ſmall town of Germany, in the duchy of Oldenburg, ſituated on the river Weſer, where the duke of Oldenburg exacts a conſiderable toll from all veſſels ſailing up the river towards Bremen. At the peace of Luneville, the duke was offered an indemnity for this toll, with the view to favour the commerce of Bremen; but its produce is ſo important, that the duke would not conſent to its abolition.

ELSGAU, a bailliage of Switzerland, being part of the biſhopric of Baſle, lying between the mountains and the Larg, and comprehending the town and bailiwick of Porentru, and 20 pariſhes.

ELSHEIMER, ADAM, in *Biography*, a painter of very extraordinary talents, ſtanding quite alone in the peculiar province of the liſt he adopted, *viz.* ſmall pictures of landſcapes with figures, and of ſmall figures with landſcape back-grounds. The figures being in ſome the principal object, and occupying the largeſt portion of the ſpace of the picture; and, in others, the landſcapes being the moſt important. He was born at Franckfort; at what period, thoſe who have written his life, differ much in ſtating; but the beſt authorities determine it to have been in 1574, and his death to have happened in 1620, ſo that he lived only 46 years.

He was at firſt a diſciple of Philip Uffenbach, whom he ſoon excelled, and then determined to go to Rome, where alone he could acquire that high taſte to which he aſpired.

After ſome time ſpent in ſtudy of the fine works there expoſed to his view, and an intimacy with many eminent painters, he fixed upon that ſtyle of art which has been mentioned as decidedly his own; in which no one had ever before exerted himſelf; and in which no one has ever ſince ſo highly excelled as Elſheimer.

That which renders his pictures ſo intereſting is, the grandeur of ſtyle in which they are executed. Many of his figures partake ſo much of Raphael's beſt manner of character, of action, and diſpoſition of the draperies, that if they were magnified, they would appear to be of that great maſter's own hand; and they have ſuperadded a colour which is of a ſuperior claſs; in the production of which, indeed, the ſmallneſs of their ſize was of conſiderable aſſiſtance to him; for it is by no means ſo eaſy to extend a full body of colour over a large ſurface, with equally pleaſing variety of tone, and freedom of execution; and in it to ſeparate and form the diſtinct parts as in a ſmaller one; and though it requires more neatneſs in the execution of the latter, it does not demand ſo free and ſo ready a hand to unite, to blend, and ſoften the various parts, and to give expreſſion its full force, as in the former.

His pictures exhibit great attention to nature; particularly his perſpective is very perfect, in lines, at leaſt; and he not unfrequently choſe very difficult things to manage: ſuch as working with a ſhort perſpective diſtance, and ſometimes placing his figures on the top of a hill, and ſuddenly loſing the ground, till it is recovered again in a deep valley. His landſcapes have, in general, the air of real views, and are finiſhed with wonderful attention to general form, and beautiful ſcenery. Their colour is not always exactly that of nature, but as ſeen under a peculiar illumination, like the tone which Titian has adopted in his St. Peter Martyr; giving it an air of grandeur not to be obtained, perhaps, by the brighter hues of nature.

From the extreme care and excellence with which his works are finiſhed, they were not, of courſe, in his ſhort life, very numerous; and are rarely to be met with. The richeſt collection of them in this country is at the earl of Egremont's, at Petworth, in Suſſex. There are ten pictures by him, eight of which are of one ſize, *viz.* about four inches high, by two and a half wide, or perhaps a little more. The ſubjects are, a St. Peter, St. Paul, St. John Baptiſt, Tobit and the Angel with a Fiſh, an old Woman and a Girl, an old Man with a Boy, and a Capuchin Friar, with a model of a convent in his hand. The figures in all theſe are about three inches high, yet their characters and expreſſions are juſt and excellent; and the drawing of their figures, and the draperies, in the beſt ſtyle of art. Another picture repreſents the interior of a brothel by fire and candle light, in which there are ten or more figures gaming, and indulging in the licentiouſneſs of ſuch a place, all exquiſitely wrought; with ſome expreſſions that have never been ſurpaſſed, although the figures are not more than two inches and a half high. The laſt is Nicodemus's viſit to Chriſt; but it is not of ſo good a quality as the others.

The ſubjects he choſe were generally moon light or candle light pieces, which he painted with great lightneſs, ſpirit, and delicacy of touch, and with great knowledge of the chiaro-ſcuro, and excellent colour; and with ſuch finiſh, that every part will bear the minuteſt inſpection.

While he lived his pictures bore high prices, and they of courſe were greatly enhanced on his death; one of them is mentioned by Houbraken, repreſenting Pomona, as having ſold for 800 German florins. There are engravings from many of Elſheimer's pictures by his friend and benefactor, count Gaud; but they are in general too heavy and black, and have a flatneſs of effect, particularly in the trees, very unlike the originals; among them is one from his moſt famed picture, the Flight into Egypt, a moonlight. It is now, with two others of different ſubjects, in the National Muſeum at Paris.

Elſheimer, though thus endowed with taſte and ſkill, was not the favourite of fortune. Notwithſtanding he obtained great prices for what he did, yet his care in the execution of them, and the time they coſt him to finiſh, were not ſo recompenſed as to enable him to live and maintain a large family with comfort. As what he earned by his paintings would not find ſuſtenance for himſelf and them, he fell into debt, and was caſt into priſon; the diſgrace of which, though he was not ſuffered to remain long confined, is ſaid to have preyed on his ſpirits, and haſtened his diſſolution. He was greatly regretted, and his works eagerly bought up, even by the Italians. The grand duke of Tuſcany had ſeveral of them, and the world juſtly lamented the ſevere fortune of ſo extraordinary a genius, who deſerved far more felicity than he was permitted to enjoy.

Elſheimer is highly celebrated, ſays another writer, for his careful pencil and extraordinary effects of light. Moſt of his landſcapes are illumined by fire, or by moon, or torch light; and in them he has introduced ſmall hiſtorical figures, which are highly appropriate to the ſcenes, and moſt exquiſitely painted: yet his Aurora, of which there is an excellent print by count Gaudt, ſhews that bright and ſudden light was not abſolutely neceſſary to the diſplay of his powers, and that he dipped his pencil in early dawn, with equal felicity.

The accuracy of his obſervation, and the retention of his memory were great, and the ſkill was ſcarcely leſs with which he introduced into his compoſitions, ſuch pictureſque incidents as he had once ſeen. Pilkington ſays that "it is impoſſible to conceive any thing more exquiſite in painting than the productions of the pencil of Elſheimer; for whether we conſider the fine taſte of his deſign; the neatneſs and correctneſs of the drawing of his figures; the admirable management and diſtribution of his lights and ſhades; the lightneſs, the ſpirit, and the delicacy of his touch; or the excellence of colouring; we are aſtoniſhed to obſerve ſuch combined perfections in one artiſt; in whoſe works even the minuteſt parts will bear the moſt critical inſpection, and the whole together is inexpreſſibly beautiful. He underſtood the principles of chiaro-ſcuro to the utmoſt perfection; and ſhewed the ſolidity of his judgment in the management of his ſubjects, which for the moſt part were night-pieces, by candle, or torch light," &c.

With theſe high claims to contemporary patronage, it was the fate of Elſheimer to fall a martyr to his own merits. Not affluence, nor even comfort, attended him in his profeſſional purſuits. His family was numerous, and the great care with which his ſenſibility to the minuter beauties of nature prompted him to finiſh his pictures, occupied ſo much time, that he was gradually overwhelmed with debts, and caſt into priſon. Being much reſpected, he was ſoon releaſed; probably by his friend Gaudt, the engraver: but returned, ſpirit-broken, to his art, and ſurvived not long. Poſterity will reverence his profeſſional merits, and regret his misfortunes.

Of artiſts of tranſcendant talent, it has been the frequent lot to receive from their contemporaries but a trifling earneſt, either of the value of their works, or the extent of their fame: ſo blind is taſte, with all its lofty pretenſions, or ſo reluctant is human nature to recogniſe the claims of living excellence.

Among the moſt celebrated of his works, which are known through Europe, by the diffuſion of count Gaudt's excellent engravings after them, may be mentioned his "Flight into Egypt," wherein he has contraſted the effects of fire and moonlight; two landſcapes, in each of which he has introduced "Tobit and the Angel;" a "Cottage Door by Candle-light, with Ceres drinking from a Pitcher;" the ſtory of "Baucis and Philemon;" the "Decollation of John the Baptiſt;" "Latona and her Sons, with the Lycian Peaſants metamorphoſed into Frogs;" and the "Death of Procris:" the two latter ſubjects were engraven in England by Magdalen Paſs. Some of his moſt valued performances were late in the gallery of the grand duke of Tuſcany. L.

ELSHOLTZIA, in *Botany*, ſo named by profeſſor Willdenow in memory of a Pruſſian botaniſt, John Sigiſmund Elſholtz, who lived in the middle of the 17th century, and publiſhed a *Flora Marchica*, or catalogue of plants cultivated in the principal gardens of Brandenburg, printed at Berlin in 1663, in ſmall 8vo. Willdenow mentions alſo a manuſcript work on Horticulture by the ſame writer in his native tongue, preſerved in the royal library of Berlin.—Willden. in Römer Uſteris Magazine, faſc. 11. 1. t. 1. Sp. Pl. v. 3. 59. Claſs and order, *Didynamia Gymnoſpermia*. Nat. Ord. *Labiatæ*, *ſect.* 3. Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, bell-ſhaped, with ten furrows, and five oblong acute teeth; the orifice cloſed with hairs. *Cor.* of one petal, ringent: tube cylindrical, ſhort, the length of the calyx: upper lip ſhorteſt, obtuſe, concave, four-toothed, clothed externally with long white hairs; lower obtuſe, ſtraight, ſharply crenate, externally clothed with hairs. *Stam.* Filaments four; the two uppermoſt ſhorteſt, lodged in the upper lip; the two lowermoſt in the under one: anthers roundiſh. *Piſt.* Germens four, roundiſh, ſuperior: ſtyle thread-ſhaped: ſtigma cloven. *Peric.* none. *Seeds* four, naked, browniſh, in the bottom of the calyx. Willdenow.

Eſſ. Ch. Calyx tubular, five-cleft. Corolla ringent: upper lip four-toothed; lower longeſt, undivided, finely crenate. Stamens diſtant.

1. E. *criſtata*. Willd. as above. (Hyſſopus ocymifolius; Lamarck Encycl. v. 3. 187.) "Spikes ſolitary, erect." Native of Siberia, about the lake Baikal. *Root* annual, fibrous. *Herb* with the habit of an *ocymum*, and a very fragrant ſcent, eſpecially when rubbed after drying, compared by ſome to roſes, but in our opinion more reſembling the muſcat grape. *Stem* a foot or more in height, ſquare, leafy, with oppoſite branches. *Leaves* ſtalked, oppoſite, ovate, acute, ſerrated, light green, ſmooth. *Spikes* terminal, ſolitary, ſtalked, unilateral, conſiſting on one ſide of a double row of obovate, pointed, imbricated bracteas, and on the other of three or four denſe rows of pale lilac-coloured flowers. This plant is propagated by ſeed, with little trouble, in our gardens, but has more ſingularity than beauty in its aſpect. The ſcent indeed renders it deſirable.

2. E. *paniculata.* Willd. Sp. Pl. v. 3. 59. (Hyſſopus criſtatus; Lamarck Encycl. v. 3. 187. Manám-podam; Rheede Hort. Mal. v. 10. 129. t. 65.) "Spikes panicled, reflexed." Native of moiſt places on the coaſt of Malabar. Lamarck, who had in his poſſeſſion fine ſpecimens of this plant from Sonnerat, aſſures us that the leaves are not alternate, as drawn in the *Hortus Malabaricus*, but oppoſite as in the preceding ſpecies, with which he rightly perceived its generic affinity. The chief ſpecific difference ſeems to be in the infloreſcence, which in the plant we are deſcribing is panicled, each branch of the panicle conſiſting of a numerous ſeries of reflexed ſpikes, ſhorter than in the former, with more oblique, unequally cordate, bracteas. Every part of this herb is ſaid to exhale an agreeable aromatic odour. The root ſeems to be annual.

ELSIMBURG, in *Geography*. See Helsinburg.

ELSINEUR, in Daniſh *Helſingoer*, a handſome town of Denmark, in the iſland of Zealand, at the entrance of the Baltic, oppoſite the Swediſh coaſt, 20 miles N. of Copenhagen. E. long. 12° 34′. N. lat. 55° 58′. The population amounts to between 6 and 7000 individuals. It derives its name from the Helſingers, an ancient Gothic colony, and is ſituated on the declivity of a hill, almoſt directly over-againſt Helſinburg, in the Swediſh province of Scania. The paſſage is not above 4 Engliſh miles. The narrow arm of the ſea, which joins the North ſea and the Baltic, is called the Oereſund, or *Sound*, and is protected by the caſtle of *Cronenburg*, which ſee.

Till the year 1425, when king Erick of Pomerania beſtowed on it the privileges of a city, Elſineur was but a ſmall inſignificant place. It has two churches, a grammar-ſchool, ſeveral handſome private buildings, and a ſugar-houſe. In 1753, a harbour was attempted, but the execution of the project was found impracticable. The road-ſtead, however, is excellent.

The principal trade of Elſineur is in wine and ſpirituous liquors; but it derives all its importance from the Sound dues, which, in times of peace, are paid at Elſineur by all veſſels paſſing through the Sound from either the Baltic or the North ſea. The cuſtom-houſe, where theſe duties are paid, is a very fine building, and it is on account of this toll, that all nations trading in the Baltic keep a conſul at Elſineur. The Sound dues are in proportion to the ſize of the ſhip and to the value of the cargo. They were originally a mere contribution to the expence of keeping light-houſes on the coaſt.

The number of veſſels of different nations that ſailed through the Sound and paid the dues at Elſineur, was in

1768 - - - -	6,30 veſſels.
1778 - - - -	8476
1788 - - - -	9224
1792 - - - -	12,114
1798 - - - -	9508
1802 - - - -	12,130
1803 - - - -	11,631
1804 - - - -	10,579
1805 - - - -	11,587
1806 - - - -	7 40
And in the firſt three months of	
1807 - - - -	342

From which ſtatement it appears, that the Baltic trade has been moſt conſiderable in the years 1792 and 1802, which both preceded the two late ruptures between England and France. See Sound.

ELSNABBAN, a ſea-port town of Sweden, in the province of Sudermania, on the coaſt of the Baltic; 32 miles E.N.E. of Nikioping.

ELSNER, James, in *Biography*, a doctor of theology, was born, in 1692, at Saalfield, in Pruſſia, and was deſtined by his father for trade, to which, however, he felt ſo ſtrong a diſinclination, that nothing could overcome it. He was accordingly ſent to the univerſity of Konigſberg, where he became private tutor to ſome young noblemen, and was afterwards appointed chaplain in the garriſon to field-marſhal count Alexander Von Dohm. He next went to Utrecht and Leyden, where he formed an intimacy with the moſt eminent literary characters of thoſe cities. In the year 1719, he publiſhed a work on the delivery of the law on Mount Sinai, and ſhortly after the firſt volume of his "Sacred Obſervations on the New Teſtament." In the following year he left Holland, at the invitation of his Pruſſian majeſty, by whom he was appointed profeſſor of theology and the oriental languages at Lingen, having firſt taken his degree of doctor at Utrecht. From this place he was called to Berlin to reſtore the reputation of Joachim's ſchool, which had fallen into much diſrepute for want of proper diſcipline. Elſner performed all that was required of him, and attained a high degree of reſpect, by the dignity and firmneſs of his manners. In the autumn of 1722, he pronounced an inaugural diſcourſe on the obligation of uniting piety to learning; and immediately after this, he was choſen a member of the Royal Academy of Sciences. Other preferments were conferred upon him, and he was always very fully employed either as a preacher or an author; and, in 1742, he was appointed director of the claſs of the belles-lettres in the Royal Academy; and when the ſociety was renewed in 1744, he retained the ſame office, and maintained the character which he had heretofore ſupported, as well by his attention to his academical duties, as by the learned diſſertations with which he enriched the memoirs of the inſtitution. He died of a fever on the eighth of October, 1750. His works are very numerous, and on various topics, but chiefly in theology. He publiſhed alſo, "A new deſcription of the ſtate of the Greek Chriſtians in Turkey," in which he received very important aſſiſtance from Athanaſius Doroſtamos, who came to Berlin to collect money for the Chriſtian ſlaves in England.

ELSTER, originally *Halſtrow*, in *Geography*, a ſmall town of the kingdom of Saxony, in Upper Luſatia, on a river called the *Black Elſter*, remarkable for its manufacture of knitted ſtockings.

ELSTERBERG, a ſmall town of the kingdom of Saxony, in the circle of Voigtland, between ſome high hills on the river Elſter, with an old ruined caſtle. It has a grammar-ſchool, about 2000 inhabitants, and a flouriſhing manufacture of ſtuffs and woollen cloth.

ELSTERWERDA, a ſmall town of the kingdom of Saxony, in the circle of Meiſſen, on the river Elſter, with a fine hunting caſtle and a beautiful park. It has only 700 inhabitants; but is remarkable for a canal which was dug here in 1740, and by means of which it has a conſiderable timber trade to Meiſſen and Dreſden.

ELSTOB, William, in *Biography*, was born at Newcaſtle-upon-Tyne, in the year 1673. He was educated at Eton and Cambridge, but the latter place not being congenial to his health, he removed to Queen's college Oxford, where he was choſen fellow and tutor. In the year 1697, he took his degree of M. A., and in 1702 was appointed rector of the united pariſhes of St. Swithin and St. Mary Bothaw in London. He died in 1714, when he was only forty-one years of age. He publiſhed ſeveral works, and had collected materials for a hiſtory of Newcaſtle. He had likewiſe projected many literary deſigns, of which the moſt important, was an edition of the Saxon laws, with great additions, together with notes of various learned men, and a prefatory hiſtory of the origin and progreſs of the Engliſh laws, down to the Conqueror and to Magna Charta. This great work was completed in 1721 by Dr. Wilkins, who deplores the loſs which the literary world had ſuſtained in the early death of Mr. Elſtob. He intended alſo a tranſlation, with notes, of Alfred's Paraphraſtic Verſion of Oroſius, of which his collections came into the poſſeſſion of the late Dr. Tegge. This work was afterwards publiſhed by the Hon. Daines Barrington, with an Engliſh tranſlation, who made uſe of Mr. Elſtob's tranſcript. Biog. Brit.

Elstob, Elizabeth, ſiſter of the preceding, was attached to the ſame kind of purſuits, and was born at Newcaſtle in 1683. From a very early period ſhe ſhewed a ſtrong predilection for literary purſuits. She reſided at Oxford during her brother's continuance at that univerſity, and is deſcribed as having been the *indefeſſa comes* of his ſtudies. She probably accompanied him to London, and aſſiſted him in his antiquarian purſuits. To one of his publications, *viz.* the Homily on St. Gregory's day, ſhe gave an Engliſh tranſlation, and a preface in vindication of female learning. By the encouragement of Dr. Hickes, ſhe undertook a Saxon Homiliarium with an Engliſh tranſlation, notes, and various readings, but only a few of the homilies were printed at Oxford in folio. In the year 1715, ſhe publiſhed a "Saxon Grammar," the types for which had been cut at the expence of lord chief juſtice Parker, afterwards earl of Maccleſfield. After the death of her brother, her circumſtances were ſo very low, that ſhe was reduced to the neceſſity of keeping a ſchool at Eveſham, in Worceſterſhire. By the interceſſion of ſome friends, queen Caroline allowed her a penſion of twenty guineas, which was paid very regularly till the death of that princeſs, when ſhe was again reduced to great difficulties, and had recourſe to education as a refuge from poverty. In 1739, ſhe was received into the family of the ducheſs of Portland, where ſhe continued till her death in the year 1756. Biog. Brit.

ELSYNGE, Henry, was born at Batterſea in 1598, and received his education at Weſtminſter-ſchool, and Chriſt-church college, Oxford. From the univerſity he went to the continent, and ſpent ſeven years in foreign travel. Upon his return he was, through the intereſt of archbiſhop Laud, elected clerk of the houſe of commons, the duties of which office he performed with ſingular ability, and much credit. He acquired the eſteem of all parties in the midſt of much diſcord and faction, and kept his poſt under the long parliament till December 1648, when he choſe to retire rather than take a part in the trial of the king. After this, he declined public buſineſs till his death in 1654. As an author his chief publication was entitled "The ancient Method and Manner of holding Parliaments in England." This was firſt printed in 1663. Anthony Wood ſuppoſed that it was chiefly tranſcribed from a MS. of the author's father, who was clerk of the houſe of lords, but there is no doubt it received many valuable additions from our author's own parliamentary experience. Mr. Elſynge left a tract concerning proceedings in parliament, never publiſhed; and alſo other tracts and memorials. Biog. Brit.

ELTEN, in *Geography*, a ſmall town of Germany, in the new kingdom of Weſtphalia, formerly a free imperial abbey, which was ſecularized at the peace of Luneville, and given as an indemnity to the king of Pruſſia, who loſt it again at the peace of Tilſit in July, 1807.

ELTERLEIN, a ſmall town of the kingdom of Saxony, in the circle of the Ertzgebirge, ſituated between Annaberg and Grunhayn, with about 1000 inhabitants. It is chiefly remarkable for the adjacent mines, which yield excellent magneſia and a very fine potters' clay for china. There is likewiſe a good manufacture of thread lace at Elterlein.

ELTHAM, a large village in the hundred of Blackheath and lathe of Sutton, in the county of Kent, England, conſiſts of 256 houſes, which are occupied by 1627 inhabitants. Its ancient name was Eald-ham, the old manſion or dwelling. John de Veſei, lord of Eltham, procured a grant of a market for this manor; and two other grants relating to it are extant among the records in the Tower. The market appears to have been diſcontinued in the time of James I., when the royal palace, the remains of which ſtand about two furlongs ſouthward from the village, ceaſed to be viſited by our kings.

Eltham palace was for ſeveral centuries a favourite retreat of the Engliſh ſovereigns, to which, probably, its vicinity to the metropolis contributed, as well as the pleaſantneſs of its ſituation. When it was originally built is unknown, yet it muſt have been prior to the year 1270, when Henry III. kept a grand public chriſtmas here, accompanied by his queen and all the great men of the realm. In the next reign, Anthony Bec, the warlike biſhop of Durham, obtained poſſeſſion of it, and conſiderably improved it: he died here in 1311. Edward II. frequently reſided here; and in the year 1315, his queen was delivered of a ſon in the palace, who was called John of Eltham, from the place of his birth. Edward III. held a parliament here in 1329, and another in 1375, when the Commons petitioned him to make his grandſon, Richard de Bourdeaux, prince of Wales. Edward IV. was at a great expence in repairing the palace, where, in 1482, he kept his chriſtmas in a very magnificent and coſtly manner, two thouſand perſons being daily fed at his charge. Moſt of the ſucceeding monarchs, to the time of Henry VIII., reſided much in this palace; but on the riſe of Greenwich it was gradually deſerted. The change which it has undergone is exceedingly ſtriking: formerly the abode of ſovereigns, and the birth-place of princes, it is now a farm; and the beautiful great hall, where parliaments were held, and entertainments given in all the pomp of feudal grandeur, is now uſed as a barn for the houſing and threſhing of corn. The area, in which the buildings ſtand, is ſurrounded by a high ſtone wall, that has been partially repaired and ſtrengthened by arches, &c. of brick, and a broad and deep moat, over which are two bridges, nearly oppoſite to each other, on the north and ſouth ſides. The hall is a moſt noble remain, meaſuring 100 feet in length, by 56 broad, and about 60 high. The windows have been extremely elegant, but are now bricked up. The roof is of timber, curiouſly wrought in the manner of that of Weſtminſter-hall, and richly ornamented with finely carved pendants. Three parks, well provided with deer, were formerly connected with this palace: in the largeſt, which includes an area of two miles in circumference, ſtands a reſpectable manſion, called Eltham lodge. Haſted's Hiſtory of Kent.

ELTMAN, a town of Germany, in the circle of Franconia, and biſhopric of Wurzburg; 8 miles W.N.W. of Bamberg, and 40 E.N.E. of Wurzburg.

ELVAS, formerly *Jelves*, a town and biſhop's ſee of Portugal, in the province of Alentejo, containing three pariſh churches, ſeven convents, two hoſpitals, and 12,500 inhabitants, including the diſtrict, in an open and fruitful territory, 18 leagues N.E. of Evora, and ſix W. of Badajoz, in Spain. It has a caſtle on an eminence, and is commanded by Fort la Lippe, a new and ſtrong fortification on the top of a hill. Here is a remarkable aqueduct, ſupported in ſome places by three arches one over the other; the ſtreets are narrow, irregular, and dirty; and the houſes are indifferently built. At ſome diſtance from the town the country is bleak and barren. N. lat. 38° 44'. W. long. 7°.

ELVÆ. See Elfs.

ELUDING, the act of evading, or rendering a thing vain, and of no effect: a dextrous getting clear, or eſcaping out of an affair, difficulty, embarraſſment, or the like.

We ſay, to elude a propoſition, &c. The deſign of chicanery is, to elude the force of the laws; this doctor has not reſolved the difficulty, but eluded it. Alexander, ſays the hiſtorian, in cutting the Gordian knot, either eluded the oracle, or fulfilled it: "Ille nequicquam luctatus cum latentibus nodis, Nihil, inquit, intereſt, quomodo ſolvatur; gladioque ruptis omnibus loris, oraculi ſortem, vel eludit vel implevit." Q. Curt. 13.

ELVEN, in *Geography*, a ſmall town of France, in the department of Morbihan, chief place of a canton in the diſtrict of Vannes, with a population of 3829 individuals. The canton contains five communes and 9136 inhabitants, upon a territorial extent of 220 kiliometres.

ELVERDINGHE, a ſmall town of France, in the department of the Lys, chief place of a canton in the diſtrict of Ypres, with 2729 inhabitants. Its canton has a population of 9057 individuals diſperſed in 9 communes, on a territorial extent of 112½ kiliometres.

ELVERS, in *Ichthyology*, an Engliſh name for a ſmall ſort of eels, caught in ſome parts of the kingdom, particularly about Glouceſter and Tewkſbury. Theſe are, in reality, young congers, or ſea-eels. They get up into rivers while very ſmall, and as they precede the ſhads, it is conjectured that they ſupply them with food. They are taken in prodigious numbers in the rivers, in dark nights, by a kind of ſieve made of hair-cloth, fixed to a long pole, and are eſteemed a very delicate food. Willughby.

EL-VISO, in *Geography*, a well built town of Spain, in the province of New-Caſtile, and diſtrict of La Manche, containing a pariſh church, a convent, a palace of the marquis D'El-Viſo, and 3500 inhabitants, about 20 leagues S.W. of Alcaraz; and 13 S.S.E. of Ciudad Real, ſituated in a fertile plain, producing corn, wine, and fruits.

ELVIUS, Peter, in *Biography*, was born at Upſal in 1710, and applied himſelf in early life to the ſtudy of mechanics, under able maſters. In the year 1738, the royal college of Mines entruſted him with the care of its collection of machines. His own knowledge enabled him to conſtruct a fulling mill on new principles. In 1743 he undertook, with M. O. Hamren, a tour through the kingdom of Sweden, to examine where the beſt ſituations could be obtained for works to be driven by water; and on this occaſion he drew plans of thoſe places which ſeemed moſt convenient for the purpoſe. For this ſervice he obtained a place in the academy of Upſal, and applied himſelf to the calculation of chances and probabilities, which led him to conſider the exiſting bills of mortality, and the means for rendering them more accurate and uſeful. He was a diligent obſerver of the heavens, and on the iſland of Huen ſearched out the ruins of the reſidence of Tycho Brahe, and made ſome celeſtial obſervations amidſt the remains of Uranienburg. He died at the early age of 38, on the 27th of Sept. 1749, and the Academy of Sciences, to which he had been the ſecretary, cauſed a medal to be ſtruck in honour of his memory. Gen. Biog.

ELUL, in *Chronology*, one of the Hebrew months, anſwering partly to our Auguſt and September. There are but nine and twenty days in it. It is the twelfth month of the civil year, and the ſixth of the eccleſiaſtical. Upon the ſeventh or ninth day of this month the Jews faſt, in memory of what happened after the return of thoſe who went to view the promiſed land. Numbers, xiii. xiv.

Upon the twenty-ſecond of this month, the feſtival of the xylophori was obſerved, when wood was carried to the temple. Selden ſays, that it was celebrated on the eighteenth day of the month Ab. On the twenty-ſixth of the ſame month, the dedication of the walls of Jeruſalem by Nehemiah was commemorated. Joſeph. lib. ii. cap. 17. p. 811. Nehem. xii. 27, &c. Calmet, Diction. Bibl.

ELVO, in *Geography*, a river of Italy, which runs into the Seſia, 2 miles N. of Vercelle.

ELUSA, in *Ancient Geography*, a town of Paleſtine, in Idumæa, W. of Jordan, according to Ptolemy. This town was once an epiſcopal city, and it is placed by P. Hardouin in the third Paleſtine.

Elusa, called alſo *Eluſæ*, and *Civitas Eluſatium*, a town of Gaul, was formerly the metropolis of Novempopulania, and maintained that rank till the eighth century. But upon its deſtruction by the Normans, the ſee of Auch was advanced to the rank of Metropolitan. Some remains of this place retain the name of Ciutat near Euſe.

ELUSATES, the inhabitants of Eluſa, who occupied the N.W. diſtrict of Armagnac. Cæſar mentions them, and places them between the Taruſates and the Garites.

ELUTRIATION, or *waſhing over*, is a method of ſeparating ſubſtances of different ſpecific gravities from each other by means of water. For this purpoſe the mixture is ſtirred about briſkly in a veſſel full of water, and when the heavier particles have again fallen to the bottom, the water, ſtill turbid with the lighter ones that are as yet ſuſpended, is poured off into another veſſel, to the bottom of which they, in a ſhort time, ſubſide. By this ſimple method a ſkilful perſon will ſeparate from each other three or four ſubſtances with great exactneſs.

ELUVIES, in *Geology*, is a term uſed by Mr. Parkinſon, (Organic Remains, i. 275.) and ſome other writers, to expreſs the ſuppoſed ruins of the antediluvian earth, effected by the Noachic deluge, but which it is preſumed by others, from the Moſaic account of that miracle, did not deſtroy the exiſting vegetable productions or the fiſh, and much leſs therefore could it have effected the univerſal diſintegration of mineral ſubſtances, on which Dr. Woodward's and ſome other theories are built. Beſides, the animal and vegetable ſubſtances, which are found imbedded in the ſuppoſed poſt-diluvian ſtrata, are none of them of the ſpecies, which, by the eſtabliſhed modes of generation, have been handed down to us, immediately from thoſe individuals of each ſpecies which Noah preſerved in the ark, when the reſt were drowned by the flood.

ELUXATIO, (from *eluxo*, to put out of joint,) a diſlocation.

ELWAD-AD, in *Geography*, a town of Arabia, in the country of Yemen; about 40 miles nearly W. of Chamir. N. lat. 16° 16'. E. long. 42° 30'.

ELWALL, Edward, in *Biography*, was born at Sedgley, near Wolverhampton, in Staffordſhire. At Wolverhampton he ſettled in buſineſs, and acquired the reputation of honeſty and great integrity in his dealings. As a politician, he was diſtinguiſhed as the zealous aſſertor of the civil and religious rights of the people, and as a vigorous ſupporter of the Hanoverian ſucceſſion. He was of a ſerious and inquiſitive turn of mind, and never heſitated to proclaim his ſentiments on any ſubject that he deemed important. He conſidered the fourth commandment as binding on all generations, and not only wrote in defence of the opinion, but while in buſineſs, conſtantly ſhut up his ſhop on the ſeventh day, and opened it on the firſt day of the week; hence he was ſtigmatized as a Jew. About the year 1714 he became diſtinguiſhed as an Unitarian, and publiſhed "A true Teſtimony for God and his ſacred Law, being a Defence of the firſt Commandment of God, againſt all Trinitarians under Heaven." This drew on him the reſentment of the neighbouring clergy, who ceaſed not to purſue him with their enmity, till they procured an indictment againſt him for hereſy and blaſphemy; on which he was tried, without having had a copy of his indictment, before judge Denton about the year 1726, at Stafford aſſizes. He pleaded his own cauſe, and vindicated the principles which he had embraced with a firmneſs and preſence of mind, ſaid to have been rarely equalled in modern times, and with complete ſucceſs, for a reſpectable and honeſt jury, under the direction of an upright judge, acquitted him. Mr. Elwall was not daunted by the obloquy and proſecution which his firſt piece had drawn on him from defending with freedom the ſentiments for which he had ſuffered, but publiſhed ſeveral other tracts, having the ſame tendency. After his trial he removed to London, and became a member of the ſeventh-day Baptiſt church at Mill-yard, Goodman's fields. In the latter part of his life he frequently attended the religious aſſemblies of the quakers, and was ſometimes admitted to ſpeak among them. He died in London at an advanced age, with an unſullied reputation, about the year 1745. He had not enjoyed the advantages of a learned education; but his natural abilities, and good judgment, were ſuch as rendered his converſation agreeable to perſons in the higher ranks of ſociety, by whom he was known, and reſpected, on account of his ardent attachment to the houſe of Hanover. Speaking of himſelf, his principles, and conduct, he ſays, "I have been a ſturdy and ſtrenuous friend to my royal friend George theſe forty years and upwards, ever ſince the nation happily ſettled the crown in his illuſtrious family; and many a ſtately Jacobite and Tory have I ſilenced by dint of argument, and brought to the ground by dint of fiſt, yet generally in ſelf-defence, and not to convince his judgment." He was a man of inflexible integrity and of extenſive charity, as well as of fervent piety.

ELWANGEN, in *Geography*, a ſmall town of the kingdom of Wurtemberg, 18 miles S.E. of Halle, in Suabia, and 30 S.W. of Anſpach. It was formerly a rich abbey of the German empire, whoſe prelate ranked as a prince, and voted in the college of princes. At the peace of Luneville it was given to Wurtemberg as an indemnity for the territory which its ſovereign was forced to cede to France on the weſtern ſhore of the Rhine.

ELWY, Britain, the name of two rivers in Wales, one riſing near Gwythrin, in the weſt part of Denbighſhire, in North Wales, runs eaſtward for ſome miles, then ſuddenly turning northward above St. Aſaph, paſſes by that city, and falls into the Clwyd, about three miles below it. Another river of the ſame name riſes in the mountains to the northward of Capelton Ybedyddier, in Glamorganſhire, South Wales; and running in a ſouth-eaſterly direction paſſes Henſall park, St. Fagan's, &c. and meeting the Taf, at the Embochure, near Penarth-point, forms Penarth harbour.

ELXAI, in *Biography*. See ELCESAITES.

ELY, ISLE *of*, in *Geography*, a tract of land ſo called, is ſituated in the northern part of Cambridgeſhire, England, and was formerly ſurrounded by waters; but, in conſequence of the vaſt improvements made by draining the fens, &c. it is now merely known by the name of an iſland. The whole diſtrict, called the iſle of Ely, extends from the bridge at Tyd on the north, to Upwere on the ſouth, 28 miles in length; and from Abbot's or Biſhop's Delf on the eaſt, to the river Nene, near Peterborough, on the weſt, 25 miles in breadth: and includes ſeveral conſiderable towns and villages, of theſe the principal place is

ELY, which, though far from populous, claims, as being the ſee of a biſhop, the appellation of a city. It is ſituated on a ſmall eminence near the river Ouſe, and owes its origin to the eſtabliſhment of a monaſtery here, A.D. 673, by Etheldreda, daughter of Anna, king of Eaſt-Anglia. After her death, in 679, the government of the abbey ſucceſſively devolved on her ſiſter Sexburga, queen of Kent; Ermenilda, queen of Mercia, daughter of Sexburga, and the princeſs Werburga, her grand-daughter, all of whom were, with the foundreſs, for many centuries conſidered as ſaints. A town gradually aroſe about the monaſtery; and both remained in peace and ſecurity till the year 870, when this place of monaſtic retirement was diſcovered by the Danes, who invaded the iſle, and, though at firſt repulſed by the bravery of the inhabitants, returned in greater numbers, and overcame every defenſive effort. They put the religious to the ſword, ſet fire to the church and other buildings, and departed, loaded with the ſpoil, not only of the town and monaſtery, but alſo of all the neighbouring places, whoſe inhabitants had depoſited their valuables here for better ſecurity. Some of the inmates of the monaſtery, who had eſcaped the maſſacre by flight, returned a few years afterwards, and commenced a college for ſecular clergy, which continued till 970, when the monaſtery was reſtored to its former eſtabliſhment by Ethelwold, biſhop of Wincheſter, under the patronage of king Edgar, who, in conſideration of a large ſum paid by the biſhop, gave up to the convent the juriſdiction of the iſle, which after the Daniſh maſſacre had been annexed to the crown. Biſhop Ethelwold beſtowed large benefactions on the abbey, which now conſiſted of regular monks of the order of St. Auguſtine. Brithnoth, the firſt abbot, exerted himſelf to complete the repairs of the church. The abbey continued to proſper till the conqueſt: its privileges being previouſly augmented and confirmed by Canute, and again by Edward the Confeſſor, the latter of whom had received his education within its walls. During the confuſion which enſued on the Norman invaſion, the abbey was deprived of many eſtates; and Thurſtan the abbot, fearing that its whole poſſeſſions would be ſeized by the Conqueror, reſolved to ſupport the intereſt of Edgar Atheling, in which he was joined by ſeveral Engliſh nobles, who were determined to defend their country from the dominion of William, whom they regarded as an uſurper. A vigorous, and, for ſome time, effectual reſiſtance was made; but at length, the abbot having ſeceded from the confederacy, the ſuperior proweſs of the Norman ſoldiers prevailed. Great numbers of the Engliſh were ſlain in battle; and many of thoſe, who were made priſoners, were cruelly mutilated; ſome having their eyes put out, and others their hands and feet cut off, that they might remain living monuments of the Conqueror's vengeance, and become a terror to ſuch as diſputed his authority.

A biſhop's ſee was eſtabliſhed here in 1107, and Henry, biſhop of Bangor, was appointed the firſt dioceſan. This prelate procured many gifts and privileges for his biſhopric, and a grant of a fair for the city, to continue for ſeven days. The king granted a mandate to make an equal diviſion of the abbey eſtates, between the prelate and the abbot, but the former contrived to retain a full third of the poſſeſſions more than he was entitled to. On the ſurrender of the monaſtery to Henry VIII. that monarch granted his letter-patent, dated September 10, 1541, to convert the conventual church into a cathedral, by the title of the Cathedral Church of the Undivided Trinity; the eſtabliſhment for the performance of divine ſervice to conſiſt of a dean, a prieſt, and eight prebendaries, with other miniſters: the dean and prebendaries to form a body corporate. The biſhop of Ely poſſeſſes the rights of a lord of a county palatine, and is ſovereign within the iſle, where all cauſes are heard and determined by a judge of his appointing, who holds aſſizes, gaol delivery, and quarter ſeſſions.

The cathedral is the workmanſhip of very different periods, and diſplays a ſingular admixture of the Saxon, Norman, and Engliſh ſtyles of architecture; yet, notwithſtanding the diſſimilarity of its parts, it muſt, when conſidered as a whole, be regarded as a very magnificent ſtructure. The north and ſouth tranſepts, which are the oldeſt parts, were erected in the reigns of William Rufus and Henry I. Here the arches are ſemi-circular, as well as in the nave, which was begun in the reign of the latter monarch, and completed before 1174. Between this period and the year 1189, biſhop Rydel erected the great tower at the weſt end, which was anciently flanked on the north ſide by a building of the ſame kind as that on the ſouth: but this either fell or was taken down, and another building begun in its place. This was never carried higher than 12 or 14 feet. The interior view of this tower is particularly beautiful, it being decorated with ſmall columns and arches running round in ſeveral ſtories, and lighted by 27 windows. The lower part was repaired, and new caſed with ſtone, in the middle of the 15th century. The handſome veſtibule at the entrance, formerly called the Galilee, was built about the year 1200, by biſhop Euſtachius. The foundation of the elegant ſtructure which was originally the preſbytery, but now forms the choir, was laid by Hugh Northwold, the eighth biſhop, in the year 1234, and finiſhed in 1250. The three moſt weſtern arches were deſtroyed by the fall of the lofty central tower, in the night of the 12th of February, 1322. To prevent the recurrence of a like accident, Alan de Walſingham, ſub-prior of the convent, and ſacriſt of the church, a perſon eminently ſkilled in architecture, deſigned and erected the preſent magnificent octagon, which is ſupported on eight pillars, and terminated by a lantern. The capitals of the pillars are ornamented with hiſtorical carvings, repreſenting the principal events in the life of Etheldreda. This octagon is probably unequalled by any of the kind: the ſtone work was completed in ſix years, and the wood work raiſed thereon, and covered with lead, in about 15 years. The whole was perfected in the year 1342, at the expence of 2406*l.* 4*s.* 11*d.* The three arches eaſtward of the octagon were rebuilt about the ſame period, by biſhop Hotham, and are very much embelliſhed. At the eaſt end of the north aiſle is a ſumptuous chapel, erected by biſhop Alcock, who died at his caſtle at Wiſbech, in 1500. His tomb, with his effigy lying thereon, but much defaced, is placed under an arch of ſtone on the north ſide. In the ſouth aiſle, and in ſome reſpects correſponding with the former, but much ſuperior in its embelliſhments, is another chapel, which was erected by biſhop Weſt, about the year 1530, and is highly enriched with ornaments and elegant tracery, &c. Both theſe chapels were greatly dilapidated by the enthuſiaſtic reformers who ſprung up during the civil wars, and ſeem to have had an invincible antipathy to every religious edifice that diſplayed taſte and elegance.

The extreme extent of the cathedral, from eaſt to weſt, is 535 feet; but the interior length is only 517. The length of the tranſept is 190 feet, the height of the lantern over, 170. The extreme height of the weſtern tower 270, and the tower on the ſouth wing of the latter 120. The length of the nave is 203 feet, and the height of the roof over it 104. The height of the eaſtern front to the top of the croſs is 112 feet. Near the eaſt end of the cathedral, on the north ſide, is St. Mary's chapel, now Trinity church; it having been aſſigned to the uſe of the inhabitants of that pariſh ſoon after the Reſtoration, by the dean and chapter. This elegant ſtructure was commenced in the reign of Edward II. and is one of the moſt perfect buildings of that age. The ſhape is an oblong ſquare; the interior length being 200 feet, the breadth 46, and the height of the vaulted roof 60. This building has neither pillars nor ſide aiſles, but is ſupported by ſtrong buttreſſes, ſurmounted with pinnacles. The ſpaces over the eaſt and weſt windows were formerly decorated with ſtatues, and a variety of well-executed ſculpture: and the interior was embelliſhed with niches highly carved, and enriched with ſtatues, ornamental foliage, and flower-work. This edifice was built at the charge of the convent by John de Wiſbech, one of the monks, and Alan de Walſingham, who erected the octagon. The firſt ſtone was laid by the latter on Lady-day, 1321. The cloiſters, and other buildings belonging to the monaſtery, have been long ſince demoliſhed, with the exception of the refectory, which has been converted into the deanery; and an elegant little chapel built by prior Crauden, now uſed as a granary, adjoining to it.

The principal charitable benefaction for the uſe of the poor of Ely is veſted in the churchwardens, and ariſes from eſtates in the neighbourhood, bequeathed by —— Parſon, about the year 1425. Here is alſo a free-ſchool, ſupported by the dean and chapter; and a charity-ſchool for twenty-four boys, who are educated and cloathed by the income of an eſtate bequeathed by Mrs. Needham about 1740. The police of Ely is regulated by the magiſtrates, who are appointed by the biſhop, and are juſtices of the peace within the iſle. Theſe meet for the diſpatch of buſineſs every market-day, which was altered in 1802 from Saturday to Thurſday. This city is the only one in England not repreſented in parliament. Many of the houſes are of ſtone, and ſome of them have an ancient appearance. The ſtreets are irregular, and, with the exception of the principal one, neither lighted nor paved. The population, as aſcertained under the late act, was 3713; the number of houſes about 700. The chief employment of the inhabitants is gardening, which is carried on in this neighbourhood to a great extent. Cambridge, St. Ives, and even London, receive conſiderable ſupplies of vegetables from this place. Great quantities of ſtrawberries are alſo reared here, and ſome other fruits; but theſe are chiefly conveyed in barges to Lynn, and carried thence by the veſſels employed in the coal trade to Newcaſtle-upon-Tyne, and other places in the north of England.

The Rev. James Bentham, author of "The Hiſtory and Antiquities of the conventual and cathedral church of Ely," was a native of this city. Some account of this gentleman has already appeared in this work. (See BENTHAM.) An intereſting and well written account of Ely cathedral has recently been publiſhed by the Rev. Mr. Miller, of this place. See alſo Lyſons's Magna Britannia, vol. ii.

About one mile from Ely is Tatterſall-hall, which derived its name from the late Mr. Tatterſall, of ſporting memory, and is now poſſeſſed by his ſon.

ELY, *Elie*, or *Ellie*, a pariſh of Fifeſhire, in Scotland, within which is an ancient royal borough of the ſame name. This is ſituated cloſe to the ſea, on the ſouthern ſhore of the Frith of Forth, where there is an excellent harbour, much reſorted to by "wind-bound veſſels." Seven ſquare-rigged veſſels, carrying 1000 or 1100 tons, belong to it, and are employed in foreign trade. Veſſels of large ſize are built here; and in the town are ſome manufactories for checks, bed-ticks, and ropes. Near the ſhore rubies have been diſcovered. Contiguous to the town, in the face of Kincraig rocks, is the cave of Mac-Duff, in which it is related that Mac-Duff retreated from Macbeth and his followers. Malcolm granted many privileges to this town. Sinclair's ſtatiſtical Account of Scotland.

ELYMAIS, in *Ancient Geography*, or, as it is called by Strabo, *Elymatis*, a province of Perſia, lying between the rivers Eulæus and Oroates, and extending from the confines of Media to the Erythræan ſea, or Perſian gulf. It was formerly divided into three great diſtricts, *viz.* Meſabatene, Gabene or Gabiene, and Carbiana, and containing the following cities, *viz.* Seleucia or Soluce, on the banks of the Hedypos or Hedypnus, which Strabo calls a great city, Saſirate, at a ſmall diſtance from mount Caſyrus, Badaca, on the Eulæus, and Elymais, the metropolis of the province, famous for a rich temple conſecrated to Diana, which Antiochus Epiphanes attempted to plunder, but he was obliged by the inhabitants to retire in diſgrace to Media. This temple was afterwards plundered by one of the Parthian kings, who found in it, as we are informed by Strabo, 10,000 talents. In this country there was alſo a very rich temple conſecrated to Jupiter Belus, which Antiochus the Great attempted to plunder, but loſt his life in the attempt. The country of Elymais was inhabited, according to Pliny, by the following nations, *viz.* the Oxii, or Uxii, Mizæi, Parthuſi, Mardi, Saitæ, Hyi, Coſſæi, Parætaceni, and Meſſabatæ. The Elymæans were a powerful people, inured to the toils of war, ſkilful bowmen, and never ſubdued either by the Syro-Macedonian, or Parthian kings, but governed by their own princes. If we may depend upon the authority of Strabo, the riſe of this kingdom may be dated from the downfall of the Perſian monarchy, for the ancients are agreed that the Elymæans were ſubject to the kings of Perſia; and if they never ſubmitted to the Syrian yoke, they muſt have been firſt governed by their own princes, either in Alexander's life-time, or ſoon after his death. Nothing is known of their kings, but that they aſſiſted Antiochus the Great in his wars with Rome, but afterwards cut him off in defence of their temple. They afterwards engaged, under the conduct of their king, in a war againſt the Babylonians and Suſians, in which they were aſſiſted by the Coſſæans with 13,000 archers.

ELYMAIS is alſo a name given by ſome writers to the city of Perſepolis.

ELYMI, or HELYMI, a people who inhabited the N.W. part of Sicily, about the river Crimiſa, where were ſituated the towns of Ægeſta or Aceſta, Erice and Entella.

ELYMIA, a town of Greece, in the Peloponneſus, placed by Xenophon towards the towns of Mantinæa and Orchémene.

ELYMIOTÆ, a people of Macedonia, who occupied a plain almoſt ſurrounded by mountains, towards the ſource of the river Aliacmen, according to Ptolemy. They had to the N. W. the country of the Lynceſtes, to the N. E. Emathia, to the S. E. the Pelaſgiotide, and to the S. W. Pelagonia.

ELYMNIUM, one of the names of the iſland of Eubœa.—Alſo, a town of Macedonia, on mount Athos.

ELYMUS, in *Agriculture*, a term ſignifying lime-graſs, a genus of graſſes which are of but little uſe to the farmer, except in protecting the looſe ſandy banks on the ſea-ſhores, in different parts of the iſland; and for which purpoſe the following ſort is the moſt uſeful.

ELYMUS *Arenarius*, ſea lime-graſs, which is a kind of graſs that, with the ſea reed, helps very much, according to the opinion of Mr. Sole, to ſuſtain and keep up the looſe ſand-banks on the borders of the ſea, from the deſtructive effects of the tides.

ELYMUS, in *Botany*, ελυμος; of Dioſcorides, from ελυω, *to fold up*, alluding to the ſheath which incloſes the ſpike or ear of ſome ſpecies. This etymology applies at leaſt to the Millet or Panick, ſuppoſed to be the ancient ελυμος, but Linnæus has adopted the name for a new genus of his own, akin to *Hordeum* and *Triticum*, to which it is leſs ſuitable. Linn. Gen. 39. Schreb. 54. Willd. Sp. Pl. v. 1. 467. Juſſ. 31. Sm. Fl. Brit. 152. Mart. Mill. Dict. v. 2. Claſs and order, *Triandria Digynia.* Nat. Ord. *Gramina.*

Gen. Ch. *Cal.* Common receptacle elongated into a ſpike. Perianth lateral, aggregate, conſiſting of two lanceolate glumes to each ſpikelet. *Cor.* of two valves; the outer one largeſt, pointed, awned; the inner concave, emarginate, finely fringed. Nectary a pair of oblong, acute, fringed ſcales. *Stam.* Filaments three, capillary, very ſhort; anthers oblong, cloven at the baſe. *Piſt.* Germen turbinate; ſtyles two, divaricated, ſhort; ſtigmas feathery. *Peric.* none, except the permanent corolla. *Seed* ſolitary, linear, convex at the back, concealed by the glumes.

Eſſ. Ch. Calyx lateral, aggregate, of two valves, containining many florets.

A genus of large coarſe rigid graſſes, for the moſt part perennial, with long creeping roots. This laſt quality renders the *E. arenarius*, Linn. Sp. Pl. 122. Sm. Engl. Bot. t. 1672. Knapp. t. 108, particularly valuable, as forming a natural barrier, in the looſe blowing ſand of many ſea ſhores, to the encroachments of the ocean, being indeed one of the principal means by which the induſtrious Hollanders have gained a part of their territories from the ſea. It is in England comprehended with *Arundo arenaria* and *Carex arenaria*, (ſee thoſe articles,) under the name of Marram, and acts of parliament have been made for their preſervation. The roots and leaves of ſuch graſſes being very durable, retain the blowing ſand, of which they accumulate more and more as they extend in growth upward, and thus gradually form a natural and very firm bank. In a clay ſoil they are of no avail. Of the economy of the American or Siberian ſpecies of *Elymus*, we have no information. Two annual European ſpecies, *E. Caput-Meduſæ* and *E. Hyſtrix*, are furniſhed with very long rough capillary awns, by which their ſeeds are not only wafted to a diſtance, but detained by the accumulation of blowing ſand, when they have once alighted, till they can fix themſelves by roots.

ELYOT, *Sir* THOMAS, in *Biography*, a gentleman eminent in various branches of learning, and a patron and friend of moſt of the learned men in the reign of Henry VIII., was deſcended of a good family in the county of Suffolk, and ſon of ſir Richard Elyot. He was educated at St. Mary's Hall, in Oxford, where he made a great progreſs in logic and philoſophy; but the year in which he entered (like the year of his birth) is not certainly known; it is, however, ſuppoſed to have been about the year 1514. After he had ſpent ſome years at the univerſity, he travelled into foreign countries, and, on his return, was introduced at court. His uncommon genius and extenſive learning recommending him to the favour of Henry VIII. who was a great patron of men of letters, his majeſty conferred upon him the honour of knighthood, and employed him in ſeveral embaſſies. He ſent him, particularly, to Rome in the year 1532, on the ſubject of the divorce of queen Catharine, and afterwards to the emperor Charles V. in the year 1536. Elyot was, as Wood obſerves (ſee his Athen. Oxon.) an excellent grammarian, poet, rhetorician, philoſopher, phyſician, coſmographer, and hiſtorian; and was diſtinguiſhed as much for his candour, and for the innocence and integrity of his life, as for his accompliſhments. He was admired and beloved by all the men of learning who were his contemporaries, and his memory is celebrated by them in their reſpective works, particularly by Leland, in his "Encomia Eruditorum Virorum." He was buried on the 25th of March 1546, in the church of Carleton, in Cambridgeſhire, of which county he had been ſheriff; and a monument was ſoon after erected over his grave. He poſſeſſed ſeveral manors in Cambridgeſhire, and one or more in Hampſhire.

He wrote and tranſlated ſeveral works. 1. "The Caſtell of Health," which is ſaid to have been firſt publiſhed in 1541; but Dr. Aikin obſerves, that his edition of that year is aſſerted to be "corrected, and in ſome places augmented, by the firſt author thereof." It was reprinted in 1572, 1580, and 1595. The reading of the author, as it appears from his *proheme*, or preface, was unuſually great, conſidering that he did not follow the profeſſion of phyſic, having extended to the works of all the Greek, Arabian, and Roman writers of credit. This book was greatly eſteemed, not only by the public in general, but by ſome of the faculty in his time, and is, indeed, fully as worthy of notice as moſt of the medical pieces of that age. His rules for diet and regimen, when not drawn from Galenical theory, are on the whole founded upon plain good ſenſe; and he uniformly inculcates temperance of every kind. This he carries to a degree, with regard to certain enjoyments, that would no doubt be generally thought ſomewhat too rigorous, except by ſuch a bridegroom as the old gentleman in La Fontaine, who would be pleaſed with our knight's authority to add all the months, from April to October, to the red letter days of his calendar.

We learn from the work in queſtion, that the diſeaſe now called *a cold*, began to be common in England in the time of Elyot. "At this preſent time," he ſays, "in this realme of England, there is not any one more annoyance to the health of man's body, than diſtillations from the head, called rheums." The cauſe of their being ſo much more frequent than they uſed to be forty years before, he ſuppoſes to be "banquettings after ſupper, and drinking much, eſpecially wine, a little after ſleep;" and alſo covering up the head too hot, a practice which prevailed to ſuch a degree, that he tells us, "now a days, if a boy of ſeven years of age, or a young man of twenty years, have not two caps on his head, he and his friends will think that he may not continue in health; and yet if the inner cap be not of velvet or ſatin, a ſerving man feareth to loſe his credence."

The other works publiſhed by ſir Thomas Elyot, were, 2. "The Governor," in three books, 1544, 8vo.; 3. "Of the Education of Children;" 4. "Banquet of Sapience;" 5. "Preſervative againſt the Fear of Death;" 6. "De rebus memorabilibus Angliæ;" 7. "An Apology for Good Women;" 8. "Bibliotheca Eliotæ, or Elyot's Library or Dictionary," 1541, folio; which work was afterwards augmented and improved by Cooper. He tranſlated alſo from the Greek into Engliſh, "The Image of Governance, compiled of the Arts and Sciences, by the Emperor Alexander Severus," 1556, 8vo.; and from the Latin into Engliſh, "St. Cyprian's Sermons of the Mortality of Man," 1534, 8vo.; and, "The Rule of a Chriſtian Life," written by Picus, earl of Mirandula, printed in the ſame year. (Gen. Biog. Dict. Aikin's Biog. Memoirs of Med. in Great Britain.)

ELYRUS, in *Ancient Geography*, a town of the iſland of Crete, which, according to Pauſanias, was ſituated in the mountains.

ELYS BAY, in *Geography*, a bay of the iſland of Antigua, on the N. coaſt, a little to the ſouth of Beggar's Point.

ELYSII, in *Ancient Geography*, a people who inhabited the eaſtern part of Germany.

ELYSIUM, Ελυσιος, in the *Ancient Theology*, or rather *Mythology*, a place in the inferi, *i. e.* in the lower world, or, as we ſometimes render it, in hell; furniſhed with fields, meads, agreeable woods, groves, ſhades, rivers, &c. whither the ſouls of good people were ſuppoſed to go after this life.

Orpheus, Hercules, and Æneas, are ſuppoſed to have deſcended into elyſium, in their life-time, and to have returned again. Virgil. lib. vi. ver. 638, &c. Tibullus, lib. i. eleg. 3. gives us fine deſcriptions of the elyſian fields.

Virgil oppoſes elyſium to tartara; which was the place where the wicked underwent their puniſhment.

"Heic locus eſt, partes ubi ſe via findit in ambas:
Dextera, quæ Ditis magni ſub mœnia tendit:
Hac iter elyſium nobis: at læva malorum
Exercet pœnas, et ad impia tartara mittit."

He aſſigns elyſium to thoſe who died for their country, to thoſe of pure lives, to truly inſpired poets, to the inventors of arts, and to all who have done good to mankind.

Some authors take the fable of elyſium to have been borrowed from the Phœnicians; as imagining the name elyſium formed from the Phœnician עלז, *alaz*, or עלץ, *alats*, or עלס, *alas*, *to rejoice*, or *to be in joy*; the letter *a* being only changed into *e*, as we find done in many other names; as in *Enakim*, for *Anakim*, &c. On which footing, elyſian fields ſhould ſignify the ſame thing as a place of pleaſure; or,

"—— Locos lætos, & amœna vireta
Fortunatorum nemorum, ſedeſque beatas." Virg.

Others derive the word from the Greek λυω, *ſolvo*, *I deliver*, *I let looſe*, or *diſengage*, becauſe here men's ſouls are freed, or diſencumbered from the fetters of the body. Beroaldus and Hornius, Hiſt. Philoſoph. lib. iii. cap. 2. take the place to have derived its name from Eliza, one of the firſt perſons who came into Greece after the deluge, and the author and father of the Ætolians. According to Diodorus Siculus (l. 1. c. 36.) the whole fable of the infernal regions was borrowed from the funeral rites of the Egyptians, and introduced into Greece by Orpheus. Hence Homer is ſaid to have borrowed his ideas and deſcriptions, which occur in various parts of the Odyſſey. Accordingly in the fourth book he gives the following account of elyſium in the addreſs of Proteus to Menelaus:

"Elyſium ſhall be thine; the bliſsful plains
Of utmoſt earth, where Rhadamanthus reigns.
Joys ever young, unmix'd with pain or fear,
Fill the whole circle of th' eternal year:
Stern winter ſmiles on that auſpicious clime:
The fields are florid with unfading prime:
From the bleak pole no winds inclement blow,
Mold the round hail, or flake the fleecy ſnow.
But from the breezy deep, the bleſt inhale,
The fragrant murmurs of the weſtern gale."
Pope's Od. b. iv. v. 765, &c.

The other poets as well as the philoſophers ſeem to have copied their notions of hell and of the elyſian fields from Homer. Plato, in his account of the ſtate of departed ſpirits, repreſents the ſoul of the deceaſed as paſſing into a place, which he calls divine, and as being there judged. If his life was conformable to the right of reaſon, he is advanced to a higher apartment, where he enjoys pleaſure and proſperity in the ſociety of the gods; whilſt the ſouls of bad men ſink into a noiſome abyſs, there to dwell in thick darkneſs, and to endure every kind of miſery. Socrates alſo adopted ſimilar ideas. This philoſopher diſtinguiſhed a threefold ſtate of ſouls departed. Thoſe who had neither ſingular merit nor enormous vices, inhabited the confines of Acheruſia, where, being purified by the waters of the lake, they received the rewards of the few virtues they had practiſed. The ſouls of the wicked wandered about their tombs, where they were tormented in different ways. After which, having drank the water of Lethe, they entered into new bodies, more or leſs honourable, according to their merit. The ſouls of the good went immediately into the elyſian fields. Pythagoras maintained, that the ſoul, upon its immediate ſeparation from the body, was conducted by Mercury into a place of the pureſt air, in which were the elyſian fields, called by Virgil the "aerial regions," *aerios campos*. The ſouls of the philoſophers, which were the beſt of all, became like to the gods, while thoſe of the wicked were tormented by the furies without intermiſſion. Both the one and the other, after a certain period of purification, returned to the earth to animate new bodies. Thus did this philoſopher inculcate, firſt in Europe, the doctrine of the metempſychoſis, or tranſmigration of ſouls, which he is ſaid to have borrowed from the Egyptians, and which had been taught before by Orpheus and Homer, who had borrowed it from the ſame people. Accordingly we learn from Herodotus, that the Egyptian prieſts maintained, that the ſoul does not die with the body, but is received into Amenthes, which was a place under ground, reſembling the hell of the Greek poets. Plutarch ſays, that this word denotes "that which gives, and that which receives," and adds, that it was a place in the centre of the earth, the common receptacle of departed ſouls. Hence, after a certain period, they were releaſed, and united to new bodies. The poets have delivered ſentiments ſimilar to thoſe of the philoſophers concerning the ſtate of ſouls after death, and whilſt each had his peculiar notions, all agreed, that the ſoul goes either to Elyſium or Tartarus; though they are far from being unanimous as to the ſituation of theſe two manſions. Some place the elyſian fields in the middle region of the air; ſome in the moon; others in the ſun; and others again in the centre of the earth adjoining to Tartarus. The moſt common opinion is, that they lay in one of the iſles of the ocean, called the "Fortunate iſlands," which are reckoned to be the Canaries. According to Ol. Rudbecks the elyſian fields were ſituated in Sweden. In the opinion of many of the ancients, the manſion of the bleſſed was in the charming country of Betica (the preſent Andaluſia in the extremity of Spain towards Cadiz,) whither the Phœnicians had travelled from the earlieſt times, and which was repreſented as a delicious country, poſſeſſing a fertile ſoil, abounding with enchanted groves, enriched by mines of gold and ſilver, and watered with rivers, ſtreams, and fountains. According to Homer, the infernal regions were in the country of the Cimmerians, who are ſaid to have inhabited the weſtern coaſts of Italy, near Baiæ and Puteoli, where Ulyſſes arrives on the ſame day that he takes his leave of Circe. Virgil has adopted Homer's notion, and places the mouth of hell upon the ſame coaſt, near the lake Avernus. Others, however, of the poets, place the entrance of hell at the promontory of Tenarus, where was the cave from which Hercules dragged Cerberus when he went down to hell. Others ſeek for it in Theſprotia, and Lucan refers it to the banks of the Euphrates. The ancients differ in opinion with reſpect to the time, during which departed ſouls continued in the infernal regions. Some ſuppoſe that ſouls doomed to Tartarus continued there a thouſand years, before the period of their tranſmigration commenced. Pindar fixed the reſidence of the bleſſed in the elyſian fields for ever; whence, according to Virgil and the other poets, they were to depart after a certain period of time, having drank the water of oblivion; and this period was uſually limited to a thouſand years. (See Tartarus.) The poets, Homer, Virgil, Pindar, Claudian, Catullus, &c. deſcribe the regions of bliſs under a variety of pleaſing images, ſuch as green bowers, gliding ſtreams, murmuring ſprings, charming meadows, ſerene air, perpetual ſprings, warbling birds, &c. Tibullus, whoſe imagination was voluptuous, repreſents it as abounding with mirth and all ſenſual pleaſures. Virgil admits merely chaſte and innocent enjoyments, and in this reſpect he has copied Homer.

ELYTROCELE, (from ελυΊρον, the *vagina*, and κηλη, a *tumour*,) in *Surgery*, a hernia in the vagina.

ELYTROID, in *Anatomy*, from ελυτρον, a *ſheath*, and ειδος, *form*, is a name applied to one of the coverings of the teſticle. See Generation, *Organs of*.

ELYTRON, properly a covering of any ſort, and for any ſubſtance. Hippocrates has appropriated the word to ſignify the membranes which involve the ſpinal marrow.

ELZEVIRS, in *Biography*, celebrated printers at Amſterdam and Leyden, lay claim to a ſhort notice in this work, on account of the many valuable books which were printed at their preſſes, and of the perfection to which they carried their art at a comparatively early period. The firſt of the family was Lewis, who was diſtinguiſhed for his editions from the year 1595. He was ſucceeded by Bonaventure, Abraham, and Daniel, of whom the laſt died about the year 1680. The ſmall types of theſe famous printers have a clearneſs and elegance which have rarely been equalled. Virgil, Terence, and the Greek Teſtament, printed in 1633, diſtinguiſhed by characters in red ink, are reckoned maſter-pieces; and the beſt of their claſſics ſtill maintain a high value. Moreri.

ELZT, or Eltz, in *Geography*, a town of Germany, in the country of Lower Saxony, and biſhopric of Hildeſheim on the Saale; 9 miles S.W. of Hildeſheim.

EM, or Embak, a river of Ruſſia, in the government of Riga or Livonia, which iſſues from the lake Wyrtz, and falls into the Peipus.

EMANATION, formed of the Latin *e*, out of, and *manare*, to flow or ſtream, the act of flowing, or proceeding, from ſome ſource or origin. Such is the emanation of light from the ſun; or that of effluvia from odorous, &c. bodies; of wiſdom from God, &c.

The principle of emanation was adopted from the moſt remote times by the oriental philoſophers, and by means of emanation from an eternal fountain of being, they endeavoured to explain the nature and origin of things. Zoroaſter, at an early period, maintained this ſyſtem, alleging, that various orders of ſpiritual beings, gods or dæmons, have proceeded from the deity, which are more or leſs perfect, as they are at a greater or leſs diſtance, in the courſe of emanation, from the eternal fountain of intelligence; among which, the human ſoul is a particle of divine light which will return to its ſource, and partake of its immortality; and matter is the laſt or moſt diſtant emanation from the firſt ſource of being, which, on account of its diſtance from the fountain of light, becomes opake and inert, and whilſt it remains in this ſtate is the cauſe of evil: but, being gradually refined, it will at length return to the fountain whence it flowed. This doctrine of emanation afterwards produced many fanciful opinions in theology. It was adopted by the ancient Indians, and taught under various modifications by the Brachmans. The ſame ſyſtem was likewiſe received among the Egyptians, taught by Orpheus and Pythagoras, and communicated to the Greeks either from Egypt or from the Eaſt. Wherever it originated, it was taught for many ſucceſſive ages in the more civilized regions of Aſia and Africa, and both before and after the commencement of the Chriſtian era, it gradually ſpread through the Alexandrian, Jewiſh, and Chriſtian ſchools. It was a diſtinguiſhing tenet of the Jewiſh Cabbala, of Simon Magus, and of the Gnoſtics and modern Platoniſts. This ſyſtem, as it was taught by the oriental, Alexandrian, and Cabbaliſtic philoſophers, comprehended the following tenets. All things are derived, by emanation, from one principle; which principle is God. From him a ſubſtantial power immediately proceeds, which is the image of God, and the ſource of all ſubſequent emanations. This ſecond principle ſends forth, by the energy of emanation, other natures, which are more or leſs perfect, according to their different degrees of diſtance, in the ſcale of emanation, from the firſt ſource of exiſtence, and which conſtitute different worlds, or orders of being, all united to the eternal power from which they proceed. Matter is nothing more than the moſt remote effect of the emanative energy of the Deity. The material world receives its form from the immediate agency of powers far beneath the firſt ſource of being, and is the neceſſary effect of the imperfections of matter. Human ſouls are diſtant emanations from Deity; and, after they are liberated from their material vehicles, will return, through various ſtages of purification, to the fountain whence they firſt proceeded. Nothing can be more fanciful than the numerous fictions which are blended in this ſyſtem, and which have been grafted upon it by enthuſiaſts of different deſcriptions, both philoſophical and theological; inſomuch that it has been the ſoul of enthuſiaſm and fanaticiſm. (See THEOSOPHISTS.) Some of the modern Eclectic philoſophers attempted to unite the atomic and emanative ſyſtems; and Jordano Bruno, in particular, founded his doctrine on the ancient ſyſtem of emanation. See BRUNO.

EMANATION is alſo uſed for the thing that proceeds, as well as the act of proceeding. The power given a judge is an emanation from the regal power; the reaſonable ſoul is an emanation from the divinity.

EMANATION is alſo uſed among the ſchoolmen, for the production of a leſſer thing, in order to the production of a greater, by virtue of ſome natural connection, or dependence between them.

Hence that is called an emanative cauſe (in contradiſtinction to an efficient cauſe) which produces an effect by its mere preſence, without the intervention of any action; as a roſe doth a ſmell, &c. Others, and with good reaſon, deny that there is any ſuch thing as an emanative cauſe, to produce an effect without any action. See CAUSE.

EMANCIPATION, formed from the Latin *ex*, of, and *mancipium*, a ſlave, in the *Roman Law*, was the act of ſetting a ſon free from the power and ſubjection of his father.

Emancipation differs from manumiſſion, as the latter was the act of a maſter in favour of a ſlave, the former that of a father in favour of his ſon.

The effect of emancipation was, that the goods, and moveable effects, which the ſon ſhould thenceforth acquire, ſhould be his ſole property, and not the property of his father, as they were before emancipation. Beſides, emancipation put the ſon in a capacity of managing his own affairs, and of marrying without his father's conſent, though a minor, or pupil, and under twenty-five years of age.

There were two kinds of emancipation; the one *tacit*, which was by the ſon's being promoted to ſome dignity, or by his coming of age, or by marriage; in all which caſes, the ſon became his own maſter of courſe.

The other *expreſs*, where the father declared before the judge, that he emancipated his ſon. This was not performed without ſome formality: the father was firſt to ſell his ſon imaginarily to another man, whom the lawyers call *pater fiduciarius*, *father in truſt*; of whom being bought back again by the natural father, he manumitted, or ſet him free, by a declaration before the judge. This imaginary ſale was called mancipatio; and the manumiſſion conſequent thereon, emancipatio.

Emancipation obtained in France, chiefly with regard to minors, or pupils, who were hereby ſet at liberty to manage their effects, without the advice, or direction, of their fathers or tutors. It muſt be obſerved, however, that emancipation only extended to the ſelling of moveables, and letting of leaſes, &c. of immoveables; not to the ſelling or mortgaging of immoveables; which were only done with the conſent of a curator, ordinarily a perſon appointed, when emancipated.

Formerly emancipation was performed in the ordinary courts of juſtice, when deſired by the child; but if he were a minor, the king's letter was alſo required. Though there were other ways of emancipation, as by marriage; arriving at the age of twenty years; and in ſome provinces by the death of the mother, becauſe the children were there under the power of the father and mother conjointly; ſo that the death of either of them emancipated the child.

Emancipation by marriage, in France, gave a power of marrying again, without the father's conſent though under age; but among the Romans, Cujas tells us, a widow, under twenty-five years of age, though emancipated by her former marriage, returned into the power of the father, and might not marry a ſecond time, without his conſent.

Du-Cange obſerves, that the word emancipation was alſo uſed in the monaſteries, in ſpeaking of monks promoted to any dignity, or removed from under the power of their ſuperiors; as alſo in ſpeaking of monaſteries, chapels, &c. themſelves, when exempted by the pope, from the juriſdiction of the ordinary.

EMANUEL, in *Biography*, king of Portugal, ſon of the infant Don Ferdinand, duke of Viſco, ſucceeded his couſin John II. in 1495. He was then in his twenty-ſixth year, and highly eſteemed for the excellent qualities of his mind. He began his reign by reſtoring the nobility to that conſequence in the ſtate of which it had been the policy of his predeceſſor to deprive them. He ſhewed an inclination to favour the Jews, who had been enſlaved in the former reign; but by the violence of his adviſers, he did not dare to follow the bent of his own mind, and demanded of theſe unhappy people, as the terms of their liberty, that they ſhould inſtantly profeſs themſelves Chriſtians, in name, though a period of twenty years ſhould be allowed them for their converſion. Moſt of them complied with the required condition; but others, and thoſe not a few, voluntarily put an end to their lives, rather than ſubmit to a dereliction of principle. Some of them were ſo indignant at the requiſition that they firſt murdered their own children, and then committed the raſh deed upon themſelves; thinking death in any form better than an abandonment of the religion of their fathers. In 1496 he married Donna Iſabella, daughter of Ferdinand and Iſabella of Spain, who died the next year, having firſt given him a ſon and heir. This was the period in which the new paſſage to the Indies was diſcovered by Vaſco de Gama, a circumſtance which proved the ſource of great riches to Portugal., and contributed to fix the epithet of *fortunate* upon this prince. In 1499 he married the younger ſiſter of his late wife; and in 1501, under his auſpices, the Brazils were diſcovered, which have proved a more laſting benefit to Portugal than her Indian poſſeſſions, and which has at length become an aſylum to the exiſting monarch, driven by Bonaparte from his European poſſeſſions. Emanuel, in gratitude for the important diſcoveries made in his reign, founded the famous monaſtery of Bethlehem, near Liſbon. He now adopted the plan of making conqueſts in Africa, in which he was not very ſucceſsful, but by the talents of Albuquerque he formed a very uſeful alliance with the king of Congo. Although proſperous in a high degree, he met with mortifications ſufficient to lead him to declare his purpoſe of reſigning his crown into the hands of his ſon. The eagerneſs which the young man ſhewed for power, and the marked attention which the courtiers paid him, cauſed the monarch to change his purpoſe. He died in 1521, in the 53d year of his age, at a time when he was regarded as one of the moſt powerful and ſplendid princes in Europe. Emanuel, when religion was out of the queſtion, was capable of liberal and generous conduct. He treated with great favour Don George, natural ſon of the late king, for whom his father had endeavoured to procure the ſucceſſion to the crown; and he reſtored to their titles and eſtates the Braganza family, who had ſuffered attainder and confiſcation in the late reign. In the hiſtory of his country, Emanuel ſtands very high for piety, humanity, munificence, and thoſe other good qualities that do honour to an enlightened ſovereign. Univer. Hiſt.

EMANUEL-PHILIBERT, duke of Savoy, ſon of duke Charles III., was born in 1528, and though deſtined for the church, yet by the early death of two elder brothers, he was brought up as heir to the ſovereignty. He viſited the court of the emperor Charles V., by whom he was created knight of the Golden Fleece. He accompanied Philip II. into England, and was afterwards entruſted by him with the command of his armies. He was general at the ſiege of Metz, and at the battle of St. Quintin, in 1557, in which the French ſuſtained a ſignal defeat. He married Margaret, daughter of Francis I. of France, and by that alliance regained all the dominions which his father had loſt. At the perſuaſion of ſome bigots he attempted the extirpation of the Vaudois, proteſtants of Savoy, but was defeated in his projects, and by the influence of the ducheſs, who was well diſpoſed towards the reformation, he willingly allowed them the exerciſe of their religion. He died reſpected and beloved in 1580, after a reign of 27 years. Univer. Hiſt. Moreri.

EMARGINATUM FOLIUM, in *Botany*. (See LEAF.) The term applies only to the extremity or apex of a leaf, and expreſſes a notch in that part, apparently cauſed by a greater tightneſs or contraction in the nerve, than in the ſofter more dilatable parts adjacent, which are therefore extended beyond it. The petals of flowers, however, are very often emarginate in their original conformation, as in many ſpecies of Chickweed or Sandwort.

EMASCULATION, the act of taking from a male thoſe parts which are characteriſtic of his ſex. See CASTRATION.

EMAUX *de l'Eſcu*, in *Heraldry*, the metals and colours of a ſhield, or ſcutcheon.

EMBA, or YEMBA, in *Geography*, a river of Ruſſia, which takes its riſe in the ſouthernmoſt part of the Ural mountains, and conſtitutes the border between the Uſimſkoi government and the country of the Kirchiſtzi, though the forts are much more to the weſt, namely, on the river Ural. The Emba takes up only one river of note, the Sagiſs, has a ſtrong current, but is at the ſame time very ſhallow. It is the moſt eaſterly of all the rivers that fall into the Caſpian.

EMBABE', a village of Egypt, oppoſite to Boulac, near Cairo, upon the weſt bank of the Nile, famous for the excellent quality of its butter, and for a variety of lupins, which grow in its vicinity, and called embaben. Theſe are ſold ready dreſſed in the ſtreets and markets, and they ſupply Lower Egypt. Their general appellation in the country is "termeſs." The Chriſtians of the Eaſt eat lupins as a ſtimulus for drinking brandy. Flour is made of them, which is uſed for cleaning the hands and ſoftening the ſkin. The ſtalk, reduced to aſhes, is preferred to other charcoal in the compoſition of gun-powder.

EMBALMING, the opening of a dead body, taking out the inteſtines, and filling their place with odoriferous and deſiccative drugs and ſpices, to prevent its putrefying.

The word is formed from *balm*, which was a principal ingredient in the embalmings of the ancient Egyptians.

Dr. Grew, in his Muſeum Regalis Societatis, is of opinion, that the Egyptians boiled their bodies in a large cauldron, with a certain kind of liquid balſam. His reaſon is, that in the mummies preſerved in the collection of the Royal Society, the balm has penetrated not only the fleſhy and ſoft parts, but even the very bones; ſo that they are all as black as if they had been burnt.

The Peruvians had an effectual method of preſerving the bodies of their incas, or kings, embalmed.

The mode of embalming dead bodies among the Egyptians was as follows: when a man died, his body was carried to the artificers, whoſe trade it was to make coffins; they took the meaſure of the body, and made a coffin for it, proportioned to its ſtature, the dead perſon's quality, and the price that people were willing to give. The upper part of the coffin repreſented the perſon who was to be ſhut up in it, whether man or woman. If it was a man of condition, this was diſtinguiſhed by the figure which was repreſented on the cover of the coffin; there were generally added paintings and embelliſhments, ſuitable to the quality of the perſon. Vide Caſſian Collat. 15. cap. 3. & Cicero, Tuſc. Quæſt. lib. i. Herodot. lib. ii. cap. 86. Diodor. lib. ii. cap. 5.

When the body was brought home again, they agreed with the embalmers at what rate particularly they would have it embalmed, for the prices were different; the higheſt was a talent of ſilver, eſtimated at about 258*l.* 6*s.* 8*d.* or, as others ſay, about 300*l.*: twenty minæ was a moderate one, and the loweſt price was a very ſmall ſum. They immediately ſent for a deſigner, who marked the body, as it lay extended, at the place where it ſhould be opened, on the left ſide, and the length of the inciſion. A diſſector, with a very ſharp Ethiopian ſtone, made the inciſion, and hurried away as faſt as he could, becauſe the relations of the perſon deceaſed, who were preſent, took up ſtones, and purſued him as a wicked wretch, with an intention to ſtone him.

This operation being finiſhed, the embalmers, who were looked upon as ſacred perſons, entered to perform their office. They drew all the brains of the dead perſon through his noſtrils, with a hooked piece of iron, provided particularly for this purpoſe, and filled the ſkull with aſtringent drugs; they likewiſe drew all the bowels, except the heart and kidneys, through the aperture which they had made in the ſide. The inteſtines were waſhed in wine from the palm-tree, and in other ſtrong and binding drugs. The whole body was anointed with oil of cedar, after having been filled with myrrh, cinnamon, and other ſpices, for about thirty days, ſo that it was preſerved entire, not only without putrefaction, but had a good ſcent with it. Αιγυπτιοι δε τα εντερα εξελοντες ταριχευουσιν αυτους. And the Perſians, as the ſame author, Sextus Empiricus, obſerves, were uſed νιτρῳ ταριχευειν. Sext. Empir. Pyrrhon. Hypoth. lib. ii. cap. 24.

Bodies thus preſerved are called *mummies*, from the Arabic word *mam*, which ſignifies wax, this being an ingredient in the preparation.

After this the body was put into ſalt for about forty days; wherefore when Moſes ſays, that forty days were employed in embalming Jacob, we are to underſtand him as meaning the forty days of his continuing in the ſalt of nitre, without including the thirty days paſt in performing the other ceremonies above-mentioned, ſo that, in the whole, they mourned ſeventy days in Egypt, as Moſes likewiſe obſerves.

Afterwards the body was taken out of the ſalt, waſhed, wrapt up in linen ſwaddling-bands, dipped in myrrh, and rubbed with a certain gum, which the Egyptians uſed inſtead of glue. Then the body was reſtored to the relations, who put it in a coffin, and kept it in their houſes, or in tombs made particularly for this purpoſe. There are ſome found, at this day, in Egypt, in chambers, or ſubterraneous vaults, which fully juſtify the truth of what is here ſaid.

They who were not rich enough to bear this expence, contented themſelves with infuſing, by a ſyringe, through the fundament, a certain liquor extracted from the cedar, and leaving it there, wrapt up the body in ſalt of nitre. This oil preyed upon the inteſtines, ſo that when they took it out, the inteſtines came along with it dried, and not in the leaſt putrefied. The body being incloſed in nitre, grew dry, and nothing remained beſides the ſkin glued upon the bones. They who were too poor to be at any conſiderable expence, did no more than cleanſe the inſide, by ſyringing a liquor into it; this done, they put the body, without farther ceremony, into nitre for ſeventy days, in order to dry it. Calmet, Diction. Bibl. Pococke's Deſcription of the Eaſt, vol. i. p. 230, &c.

The preſent method of embalming in Egypt differs very much from the ancient. Mallet informs us, that it is now the cuſtom to waſh the body ſeveral times in roſe-water; then to perfume it with incenſe, aloes, and other odours, in great abundance; the body is afterwards wrapped up in a winding-ſheet, made partly of ſilk, and partly of cotton, moiſtened probably with ſome liquid perfume; this is again covered with another cloth of unmixed cotton, to which is added one of the richeſt ſuits of clothes of the deceaſed. Letter X. p. 88.

The art of embalming, ſays Sonnini, is now unknown to the Egyptians. As ſoon as a perſon is dead, they preſs the different parts of the body, in order to make it diſcharge all its impurities; they repeatedly waſh it, ſhave it, pluck out all the hair, and ſtop all the apertures cloſely with cotton; they then pour upon them odoriferous waters, and the perfumes of Arabia penetrate into all their pores. The inanimate remains are then committed to the earth; and upon the ſpot where the head of the deceaſed lies, they erect a ſmall ſtone pillar, crowned with a turban. Every Friday they reſort to the foot of this ſepulchral monument, and renew their mournful adieus.

Dr. Ward, in his Diſſertations on this ſubject, ſuppoſes that the Jewiſh method of embalming was very different from the Egyptian, and that this appears from ſeveral paſſages in the New Teſtament. Both, as he conceives, ſwathed up their dead; but inſtead of the Egyptian *embowelling*, he ſuppoſes the Jews contented themſelves with an *external unction;* and that inſtead of myrrh and caſſia, they uſed myrrh and aloes. To this account he alſo adds the ſuppoſition, that St. John might mention the circumſtance of our Lord's embalming, in order the better to obviate the falſe report which then prevailed among the Jews, that the body of our Lord had been ſtolen away in the night by his diſciples; for the linen, he ſuppoſes, could not have been taken from the body and head, in the manner in which it was found in the ſepulchre, on account of its clinging ſo faſt from the viſcous nature of theſe drugs, if they had been ſo fooliſh as to attempt it. It is certain that the modern Egyptian mode of embalming, if it may be ſo called, differs very much from the ancient; but it is not eaſy to determine how far the Jewiſh method, in the time of our Lord, differed from that of the Egyptians. It does not appear indeed to be certain, that the Jews were not accuſtomed to embowel their dead in embalming. As all other nations ſeem to have embalmed exactly according to the Egyptian manner, the ſame cauſes that induced them to do ſo, probably occaſioned the Jews not to vary from them in this reſpect. It does not, however, follow from hence, that our Lord was embowelled, though St. John ſays (ch. xix. 40.), that he was buried with ſpices, "as the manner of the Jews was to bury;" for theſe words do not neceſſarily ſignify, that all was done that was wont to be done in thoſe caſes among the Jews. Indeed, the contrary appears to have been the fact, from the farther preparations made by the women, who probably were not acquainted with what had been done, though Dr. Ward ſuppoſes the contrary; ſince St. Luke expreſsly tells us (ch. xxiii. 55.), that "the women, which came with him from Galilee, followed after, and beheld the ſepulchre, and how his body was laid." Admitting this ſtatement, Ward's thought concerning the difficulty of taking off the bandages, beſmeared with very glutinous drugs, muſt appear to be unfounded; for in that caſe, the women could have done nothing more as to the embalming of him. Beſides, aloes and myrrh do not appear to poſſeſs that very glutinous quality which Dr. Ward aſcribes to them; and it is more reaſonable to ſuppoſe that St. John mentions this circumſtance, concerning which the other evangeliſts are ſilent, becauſe he publiſhed his hiſtory for the uſe of perſons leſs acquainted with the cuſtoms of the Eaſt, than thoſe for whoſe information the others wrote. This reaſon induced him to ſay to thoſe who were wont to *burn* their dead, that our Lord was *buried with ſpices*, which was *in general* the Jewiſh method of diſpoſing of their dead; and this he might very well do, though the ſhortneſs of the time occaſioned ſome deviation from what they commonly practiſed. This ſhortneſs of time prevented them alſo from ſwathing him with that accuracy and length of bandage, which they would otherwiſe have uſed; in conformity to the cuſtom obſerved among the Egyptians, and probably alſo among the Jews: for we are informed, that the Egyptians have uſed above a thouſand ells of filletting about a body, beſides what was wrapped about the head. Such, indeed, was the hurry of the diſciples, that our Lord's head was ſimply bound about with a napkin; a practice uſed by the Mahometans at this time. What was done by Joſeph and Nicodemus with the mixture of myrrh and aloes, which they provided, doth not appear. Dr. Lardner ſuppoſes, they might have formed a bed of ſpices. A modern Jew, cited by biſhop Kidder, objects to the hiſtory of the New Teſtament; alleging that the quantity was ſufficient for 200 dead bodies, that is, allowing half-a-pound for each body. But this quantity falls far ſhort of that which modern ſurgeons uſe in embalming. It appears from what Joſephus (Antiq. lib. 15.) ſays of the funeral of Ariſtobulus, the laſt of the high prieſts of the family of the Maccabees, that the larger the quantity of ſpices uſed in their interments, the greater honour was thought to be done to the dead; and therefore we may eaſily account for the quantity brought by Nicodemus, though we may not be able to tell preciſely how he diſpoſed of it. Might not large quantities of precious perfumes be ſtrewed, or deſigned to be ſtrewed, about the body of our Lord? Harmer's Obſ. vol. ii.

It is no wonder that we find human bodies preſerved without corrupting for many ages, by means of ſpices, and other ingredients, proper to reſiſt putrefaction, applied with the niceſt care; but it is ſtrange that there ſhould be a ſort of embalming performed by nature, in ſome places, where bodies are preſerved merely by the virtues of the ſoil in which they lie; yet this is evidently the caſe in ſome inſtances. We have, in the Philoſophical Tranſactions, an account of a man and a woman who were loſt in the great ſnows on the moors of Hope, near the woodlands in Derbyſhire, on the 14th of January, 1674. Theſe perſons were not found till the 3d of the May following, at which time they ſmelt ſo ſtrong, that the coroner prudently ordered them to be buried on the ſpot. Theſe bodies lay buried in the peat-moſs 28 years before they were looked at again; when ſome people of the country, who had heard of the ſtrange virtues of the ſoil thereabouts in preſerving dead bodies, opened the ground, and found them no way altered, the colour of the ſkin being fair and natural, and the fleſh as ſoft as that of perſons newly dead. Phil. Tranſ. N° 434, p. 415.

After this the place was remarked where they lay, and they were ſhewn for a ſight for 20 years, though they were much changed by having been ſo often uncovered in that time.

EMBANKMENT, in *Rural Economy*, a large body, mound, or bank of earth, conſtructed and thrown up in different ways, according to circumſtances, with the view of guarding, protecting, and defending lands on the borders of the ſea, rivers, and lakes, from being inundated and injured by them.

They are of different kinds and forms, according to the nature of the ſituations and the materials of which they are conſtituted. In embanking againſt the ſea and large rivers, where the ſlopes next them are naturally gentle and eaſy, they are moſtly of the earthy deſcription, being well put together, and covered on the ſurface with turf cut from the tough ſward of the land in the neighbourhood; but, in caſes where the banks, borders, and ſhores, are more ſteep and bold, they are uſually of a more hard and ſolid nature: being often made with ſtone, brick, gravel, ſand, ſhells, and other ſimilar ſubſtances, laid cloſely in ſome ſort of tenacious material, ſuch as clay, mortar, and other matters of the ſame quality. Wood is likewiſe, in ſome inſtances, employed in their conſtruction.

In works of this ſort, very much depends upon the form in which they are conſtructed, and the nature and management of the materials which are made uſe of in the buſineſs. In reſpect to the firſt, it may be remarked, that banks of theſe kinds are commonly conſtructed with too narrow baſes for the heights which are given them; from which circumſtance, the ſides which are oppoſed to the effects of the water become too ſteep and upright; conſequently, in caſes of high tides or floods, they are utterly incapable of reſiſting their weight, which has equally a lateral and downright preſſure. Beſides this, there is another diſadvantage attending this method of forming them, which is, that the floods, as well as the tides, in ebbing and flowing, have a more continued action on one part than would be the caſe, if the ſlopes were more gentle and gradual; conſequently, they have a much greater tendency to break down and deſtroy the ſuperficial parts of the banks. With ſome variations in the forms, moſt of the embankments in this country are, however, made in this way. They may ſucceed in ſome particular inſtances; but in general it is found, that breaches are frequently taking place in them, from the effects of the ſea or floods, which are not capable of being filled up or repaired, without conſiderable difficulty and trouble; and which, if ſuffered to continue even for a ſhort ſpace of time, endanger the whole embankment.

The common form of embankment is ſhewn at *fig.* 1, *Plate* X. *Agriculture*, and the improved form pointed out at *fig.* 2, in the ſame plate.

The angles or ſlopes of theſe ſorts of works are made very different in different caſes; but that ſhewn in the above figure ſeems in general well calculated for the purpoſe of reſiſting the impreſſion of heavy tides, or the waters of floods. The greater breadth they have in proportion to their height, the more effectual they muſt be in reſiſting the power of the waters which come upon them.

In regulating the heights of embankments, it is neceſſary to aſcertain the greateſt depth of water at the higheſt tides or floods; making the ſummits of them about two feet higher than the points to which they riſe at ſuch times. By ſome, a leſs height than this above the higheſt mark of the tides or floods has, however, been conſidered ſufficient; but it is always proper to be on the ſafe ſide, as the conſequences of an overflow are very ſerious.

In forming embankments with ſtones, or other ſimilar materials, which, as has been ſeen, is eſſential in bold ſteep banks or ſhores, it is neceſſary that they be laid in proper materials, and be cloſely jointed next the ſea, or the rivers, ſo as to be fully capable of reſiſting the entrance of water; as, unleſs this be the caſe, they will by no means be complete: for the water, inſinuating itſelf between the openings, ſinks down among the ſtones, ſoftens and looſens the clayey or earthy matters underneath, by which portions of them are continually forced out and waſhed away; hollows being formed in that way below, and the ſtones naturally ſinking down; in conſequence of which, the waters ruſh into the cavities with conſiderable impetuoſity, and quickly diſplace others, and the whole embankment is ſoon deſtroyed. This very frequently takes place with the heads thrown acroſs rivers, and ſuch paved or cauſewayed banks as are formed with the view of protecting and preſerving thoſe bold and open ſhores, which are liable to be undermined and carried away by the waſhing operation of the waters which come againſt them. In order to render the embankments perfectly ſecure in ſuch caſes, they ſhould be laid with good mortar, and be pointed with a ſtrong cement. A good coat of gravel, in ſome caſes of this kind, is even found far ſuperior to paving with ſtones.

In conſtructing embankments of the quay, or other ſimilar kinds, a mortar formed from powdered unburnt lime-ſtone and coarſe ſharp ſand is employed; the whole being pointed with puzzolana earth, by which they become as ſolid as rock, and fully reſiſt the effects of water. The lime of particular ſorts of lime-ſtone is found more proper for forming this ſort of mortar cements than that of others: thus, that found at Dorking in Surrey is ſuppoſed to conſtitute the moſt durable ſubſtance of this kind of any in the kingdom; and has been employed in forming the new docks in the river, near London. And an excellent ſort of lime-ſtone for the ſame purpoſe has likewiſe been diſcovered near Worſley, in Lancaſhire, which is there termed Sutton lime.

It has been ſuggeſted by a late writer, that an excellent mortar cement for this uſe, which hardens under water, may be compoſed by having four parts of blue clay, ſix of the black oxyd of manganeſe, and nine of carbonate of lime, ſubmitted to a white heat, and then well incorporated with ſixty parts of ſand, and as much water as may be neceſſary to form it into a mortar.

It is invariably found, in examining the ſhores of the ſea, and the banks of rivers, that ſuch as have eaſy and gently declining ſlopes from their beds to their borders or banks; and thoſe which are formed in a ſteep upright manner, of rocky materials, ſuch as are ſhewn at *figs.* 3, and 4, are the leaſt expoſed to injury from the effects of their waters: the two former being the moſt ſecure, when ſpread over or coated with good coverings of ſand or gravel, or uniformly turfed over quite down to the water-ſide with the ſward of a tough old paſture. The ſtrength and firmneſs of their banks are in proportion to the extent of the ſlope; and their durability depends on that of their being made uniform on their ſurfaces, both in reſpect to hardneſs and ſmoothneſs: as, in the former caſe, from the great length of ſlope, the flows and decreaſes of the waters act more momentarily on their different parts, and their greater weight renders their banks more firm; while, in the latter caſe, by the equality of their ſurfaces, the power of the waters is rendered the ſame on one part as another, and no obſtacles are left for the producing of eddies, or other means of forming holes or breaks in them.

In the latter, or thoſe of the bold, upright, rocky kind of banks, their ſtrength chiefly depends on the reſiſtance of the large quantity of materials by which they are backed, and not on the manner in which they are diſpoſed, as in the former caſe; and their durability, on that of the uniform compactneſs of texture in the parts oppoſed to the effects of the waters: as, where theſe have fiſſures in them, or are ſofter in ſome parts than others, the waters are liable to enter and break down the banks in time, according to the particular nature of the caſes. A ſtriking example of this kind lately occurred in the Iſle of Wight.

It is, therefore, of importance that the modes and forms of embankment, which are thus naturally preſented, ſhould be improved upon by art. It is evident, that if a cut was formed behind the embankment, as in *fig.* 5, at the letter *x*, the ſhores or banks, though, in this caſe, as it were, detached from the land, would be found equally ſtrong and capable of reſiſting the preſſure of the waters, as in their original ſtate. Hence, if a mound or bank was formed, and placed out at the diſtance of one, two, or three miles from the ſhore or other embankment, within the bed of the ſea or other waters, as at *y* in the ſame figure, it would be equally capable of reſiſting them as in the former inſtance, and not more liable to be broken down by their preſſure than in its former ſtation; and would alſo defend them as completely from the intermediate ſpace of land, as it did before from the narrow trench. Conſequently, on this principle, vaſt tracts of land may, in different parts of the kingdom, be obtained by judicious embankments.

Though the ſhores of bold ſteep coaſts may not afford examples equally capable of being followed with advantage as the above, they nevertheleſs ſuggeſt uſeful hints for the purpoſe of defence, in caſes of bold, abrupt, broken ſhores, conſtituted of earth, or of that material and rocky ſubſtances intermixed. It readily preſents itſelf to the mind, that the raiſing a good perpendicular ſtone-wall againſt ſuch banks, renders them nearly as ſtrong and laſting as thoſe formed by nature of ſteep, ſolid, rocky bodies. This ſort of walled bank is exhibited at *fig.* 6. But though this method may be practiſed, in caſes of the above kind, with great advantage, it is not by any means applicable in general to rivers; as, with them, the water, during the periods of floods, ſtands in need of room to ſpread, which is the great uſe of giving their banks a ſloping form; while, in this way, by being confined, it would have the effect of doing more injury than was the caſe before. Inſtances may, however, happen in which it may be had recourſe to with propriety, in defending a part of the bank of a river, without giving it a ſloping direction, or for protecting one part of a bank at the riſk of that which is oppoſite to it; but well-conſtructed piers, in ſuch caſes, are frequently more perfect, and conſtantly attended with leſs expence. But inſtead of theſe, art may ſuggeſt one that may anſwer in ſome reſpects more perfectly; as in place of bringing together ſuch a maſs of earthy or other ſubſtances, as may be proper for conſtructing ſuch banks as are ſhewn at *figs.* 1, and 7, it may be more advantageous to have one formed, ſuch as is ſhewn at *fig.* 8, the ſide of which next the water forms with the baſe an angle of about 45 degrees. This will be capable of bearing all the weight or preſſure of water that can poſſibly be brought upon it, equally well with that of *fig.* 1, except that the operation of the tides would break the ſuperficial part of the ſide next the ſea, unleſs prevented by coating it with ſome durable ſubſtance, ſuch as paving ſtones, bricks, or other ſimilar materials.

But various different ones may be invented between this and the firſt natural kind, which differ only in the degree of inclination which they have towards the ſea; that which ſlopes in the higheſt degree, as *fig.* 1, having the ſurface covered over with ſand or gravel; and that which has the leaſt ſlope, as *fig.* 8, may be covered with pavement; the different intermediate ſlopes being protected by materials which have a quality between the two, ſuch as coarſe gravel, chalk-ſtones, brick, and ſand, as ſhewn in *fig.* 9. This embankment is wholly conſtructed of a ſandy loam, being depoſited upon a ſoil of the ſame quality; but as it would not, for ſome time after being formed, be ſufficiently impervious to water, a column of clay is carried upright in the middle, from the clayey ſubſtratum of the ſoil underneath, as ſhewn at *x x* in the ſection.

In caſes where the ſhores are of a very ſandy nature, it is frequently neceſſary to form the embankments wholly of a ſort of wicker-work. In ſuch circumſtances, three or four rows of pailing may be put down, of different heights; and the vacant ſpaces between them be well filled, by forcing in furze, bruſh-wood, or even ſtraw, as repreſented at *fig.* 10. Theſe ſubſtances, by detaining the mud and ſand, as the tide paſſes through them, or during high floods, ſoon form a ſort of embankment, ſuch as that ſhewn in the above repreſentation. It ſhould afterwards be covered with ſome plant, which is capable of binding and giving it ſolidity, ſuch as the *elymus arenarius*. This embankment would continue, during extraordinary tides, to retain ſtill larger quantities of the ſandy materials, until ultimately raiſed higher than they could reach, by which a ſafe bank would be formed. It is ſuggeſted by Mr. Loudon, in his uſeful "Treatiſe on forming Country Reſidences," from which many of the above hints have been drawn, that from twenty to thirty thouſand acres of land might be gained in this way, in a very few years, in different parts of the rivers Severn, Humber, Frith, &c.

In all caſes of embankment, however they may be formed, tunnels and ſluices of a proper kind, with valves towards the ſea or rivers, muſt be occaſionally placed, according to circumſtances, ſo as to permit the water that may be collected within to paſs away, and that of the ſea or rivers to flow up, with different intentions in the view of improving the land.

The utility of projecting points is very conſiderable, in different caſes, on the ſea-coaſts and rivers, in defending the bays and inlets of the former, as well as guarding the banks of the latter, by diverting their ſtreams or currents to the oppoſite ſides. Hence ariſes the formation of piers, which become highly beneficial in defending embankments, as well as the borders of rivers and brooks. In the firſt of theſe caſes, they may generally be conſtituted and coated over with the ſame ſort of material as that of which the embankment is formed; while, in the latter, they ſhould be formed of ſome ſort of ſtony matter, being conſtructed in ſuch a way as to decreaſe in every direction as they advance outwards, as repreſented in *fig.* 11. In each of theſe caſes, they are, however, capable of being conſtituted of bruſh-wood, ſecured by means of ſtakes, often with more perfect ſucceſs. And it frequently happens that a ſimple rude wicker-work fence, of not more than three or four yards in length, may be fully ſufficient for the purpoſe. Embankments formed of ſtone, unleſs conſtructed in the manner repreſented at the above figure, are apt to cauſe eddies below them; while thoſe formed of bruſh-wood cannot have this effect.

It is obvious that conſiderable attention muſt be required in deciding the moſt proper ſituations for conſtructing theſe ſorts of projections in, and the diſtances to which they ſhould extend into the rivers: as a too extended projection may be highly dangerous to the oppoſite bank, and of courſe do harm inſtead of being beneficial; while not carrying them out ſufficiently may prevent the effect which is wanted. In caſes where piers are to be formed of ſtone, as in rivers where the bottoms are of a rocky nature, the plan repreſented at *fig.* 11. is probably the moſt proper, as it will ſcarcely cauſe any eddy, and be nearly equally mild with that of wicker-work in the effect which it produces. Different works of theſe ſeveral kinds have been conſtructed in the northern parts of the iſland with much ſucceſs.

Proper Materials for Embankments.—There cannot be any doubt, but that different ſorts of materials may be made uſe of in different ſituations and kinds of works of this nature, with more advantage than others, both in ſo far as duration and expence are concerned.

Thoſe ſteep upright embankments which are conſtructed with the view of protecting bold ſhores, or coaſts, and the banks of particular rivers, may probably be beſt formed of good brick, rubble, or aſhler work in the manner of a wall, as ſeen at *fig.* 6. in the plate, the materials being laid in the ſtrongeſt ſort of mortar that can be made. But where this is not the caſe, they may be built in the common way, and pointed with puzzolana earth, or what is termed the Roman cement, prepared by Meſſrs. Parker and Co. London.

The different kinds of ſloped embankments may be formed either with common earthy materials, clay, mud, or a mixture of theſe ſeveral different ſubſtances: and any other matters which are capable of uniting into a ſolid, firm, compact maſs, may be had recourſe to for the ſame purpoſe. Where the ſides next the ſea or other waters form angles of from twenty to thirty or even thirty-five degrees, with their baſes, they may be coated with ſand, the ſhells from the ſea, or coarſe gravel from the borders of the ſhores. And ſtones, broken down to uniform ſizes of a few pounds in weight, may be employed in a ſimilar manner. But where none of theſe ſubſtances are capable of being procured in ſufficient abundance, a method practiſed in Holland, of covering them with ſuch periſhable materials as mats, reeds, ſtraw, bark, and others of the ſame nature, may be had recourſe to; but theſe are obviouſly diſadvantageous, as requiring very frequent renewal. They might likewiſe be protected by a low fence of bruſh-wood, fixed in an erect manner all along at the bottom of the bank, of an equal height, as tending to break off the violence of the waves. Another method might alſo be employed, which is, that of covering the whole front of the bank with bruſh-wood, either made into bundles or in the manner of wicker-work, or fixed down in a neat manner by means of long poles and ſtrong hooked ſtakes. And further, they may be laid in the form of cauſeway with ſtones in moſs, or covered with wicker-work applied upon the moſſy material when ſpread out over the bank. And there are ſtill many other modes which may be adopted under particular circumſtances.

In all caſes where the ſides and ſlopes towards the ſea conſtitute angles of from thirty-five to forty-five degrees, with their baſes, as in *fig.* 8, recourſe may be had to ſtones of the flag kind as coverings, which ſhould be jointed with cement mortars formed in ſome of the manners mentioned above. And where theſe ſorts of ſtones cannot be provided, if clay can be found, proper kinds of bricks may be made, and uſed in the ſame way as the ſtones. But where the ſlopes or inclined planes are from forty to forty-five degrees, it is frequently more cheap and economical to have them covered with ſtones of about ſix or eight pounds in weight, applied to the thickneſs of a foot and a half or nearly two feet; or theſe may be uſed on a bed of common moſs of three inches, or of peat-moſs of the flow kind, of ſix inches in thickneſs, ſpread upon the banks, only to the thickneſs of ſix or eight inches. Stones of theſe kinds may likewiſe be formed into a ſort of cauſeway, or be laid in ſtrong clay, and their ſurfaces be jointed with lime or a ſtrong cement mortar, which has the property of quickly hardening, and of enduring the operation of the air and tides, which alternately act upon it.

There may likewiſe be caſes in which it may be the moſt advantageous practice to have the ſides next the ſea or rivers protected by coverings of wood only, in which caſes, larch may be the moſt proper, or ſuch others as are durable, having their ſurfaces covered over with pitch and ſome ſort of ſharp ſand. And old ſail cloth, or oil cloth pitched and coated over with ſand in the ſame manner; or even thin plates of metals have been ſuggeſted as uſeful in particular inſtances.

Expence of forming Embankments.—This muſt obviouſly be very different in different ſituations and circumſtances, according to materials and the price of labour, but though in general pretty conſiderable, it is ſeldom ſo high as is commonly ſuppoſed. It is probable that in cheap diſtricts, and where the materials are plentiful, the expence of forming an earth bank covered with ſand or gravel, ſuch as that ſhewn at *fig.* 1, could not be leſs than from four-pence or ſix-pence, to ten-pence or a ſhilling the cubic yard. And ſuch as have more ſteep and bold ſlopes, as from thirty-five to forty-degrees, and are formed with pavement on the ſurfaces, cannot coſt leſs than from nine-pence to one ſhilling and ſixpence the cubic yard. One made on the plan of that ſhewn at *fig*. 6. could not be conſtructed for leſs than from twelve or fifteen to thirty pounds for every thirty-two yards. And one conſtituted of bruſh-wood, in the ſame method, for ſoft ground which will not admit of a wall, would not be lower than from ſix-pence or eight-pence to ſix or ſeven ſhillings for each foot forward in a lineal manner. In many ſituations the expences would, however, in all ſorts of embankments, ſtand a great deal higher than theſe.

In ſome diſtricts embankments are formed by the rod and the floor, the former being from four to five pounds, and the latter about four ſhillings and ſix-pence, the workmen finding all ſorts of neceſſary things for the buſineſs.

Extent of Land capable of being gained by Embankments.—It is evident, that great quantities of land might in many ſituations be obtained from the ſea and large rivers by the forming of proper embankments. Some notion of this may indeed be formed by a careful examination of ſuch lands, as lie along their ſhores and banks, by aſcertaining the diſtances to which the waters ebb out at common tides, as it is found by experience, that one half of the extent of land, thus uncovered in any particular ſituation, may at leaſt be gained; hence throughout the whole kingdom it could hardly be eſtimated at a leſs quantity than from two to three millions of acres, but it is probably much more than even the laſt quantity, if it were capable of being aſcertained with any degree of accuracy or correctneſs.

Importance of Embankments.—When the extent and value of the lands which are capable of being gained by theſe means are fully conſidered, there can be no doubt of their being of the greateſt conſequence to the intereſts of the country. It has been well remarked by a late writer on this ſubject, that there are numerous places in the kingdom where vaſt improvements may be effected by the judicious application of theſe means. Vaſt tracts of land of the beſt kind may not only be gained from the ſea, but likewiſe from the large rivers and lakes, beſides the beneficial conſequences which muſt neceſſarily ariſe from the prevention of ſuch rivers from overflowing their banks, and injuring the level grounds in their vicinity by ſuch inundations. In ſome caſes, it is ſuppoſed, that by raiſing a bank of only three or four feet in height, at very ſmall expence, ſome thouſands of acres might be prevented from being overflown, the crops from being carried away, and much other miſchief from being produced. In other inſtances the forming of very trifling banks might be the means of obtaining much extent of country, which in its preſent ſtate is of but very little value; yet ſo indifferent are people in general about improvements of this deſcription, that though immenſe tracts are year after year overflown, and the moſt dreadful devaſtations committed, they have recourſe to no means of prevention; nay, even though the ſea itſelf, ſays the writer, as if to rouſe them from their inaction, preſents to their view twice every four and twenty hours large tracts that might by proper means be made of very great value, yet theſe repeated invitations are diſregarded, and no attempts are made to poſſeſs what might, in many caſes, be ſo eaſily and ſo advantageouſly acquired. This is conſidered altogether as extraordinary and unaccountable, while the acquiſition of diſtant poſſeſſions is conceived by them of ſuch great importance, as there can be no doubt but that the addition of portions of ground at home, when brought into proper cultivation, is of far greater national advantage than double the quantities gained in other diſtant countries.

The acquiſition of additional territory at home ſhould, therefore, be more attended to, and have more expence beſtowed upon it than has hitherto been the caſe. In particular ſituations, indeed, a few active and enterpriſing perſons have taken advantage of the opportunities which have been preſented; as in the counties of York, Lincoln, Cambridge, and others, many hundred thouſands of acres have been gained by embankments. In Norfolk, too, a conſiderable extent of land has been gained in this way. In the neighbourhood of Cheſter, the river Dee company have likewiſe gained ſeveral thouſands of acres from the ſea, which have been ſince divided into different beautiful farms, the whole of which pay in rent more than two thouſand pounds *per* annum. And in Holland the whole country has, in a great degree, been obtained by theſe means.

It is ſtated by Mr. Beatſon, in the ſecond volume of Communications to the Board of Agriculture, that large ſums have been expended in ſome places by individuals, with a view of guarding againſt inundations; but owing to the embankments they have made being injudiciouſly placed, and as badly conſtructed, the deſired effect has not always been produced, particularly in the northern parts of Cheſhire, on the banks of the river Merſey, where works of this kind have been thrown up at a great expence, which, from the manner of their being placed, may, in ſome caſes, by confining the courſe of the river, do more harm than good. By the appearance of that part of the country, ſo far as he could judge from the curſory view he had of it, it ſeemed to him that the inundations from that river might have been effectually prevented at a much eaſier rate, if a proper method had been taken at firſt; but from a certain ill-judged and miſtaken tenaciouſneſs of property, the embankments are reared ſo cloſe upon the ſides of the river, that, in many places, it is confined to a ſpace not more than twenty yards over. Owing to this, and to an aqueduct acroſs the river, with only one arch inſtead of two, which it ought at leaſt to have had, the water ſometimes, in great floods, riſes, he was informed, to the height of about twenty feet above its ordinary level, and overflows the embankments, although now, by frequent additions, they are about that height. Inſtead of twenty yards, had theſe embankments been eighty or a hundred yards diſtant from each other, and the river widened in the narroweſt places, one-third or one-fourth of their preſent height would have been quite ſufficient. They would have been much eaſier conſtructed, and leſs liable to damage by the floods, and a great deal of money would have been ſaved, not only in the firſt conſtruction, but in keeping the banks afterwards in repair. Neither would that ſpace of ground between the embankments and the river be altogether uſeleſs; on the contrary, it would have produced the richeſt paſture, or meadow-hay, by its frequent manurings with the fertilizing particles left upon it, when flooded by the ſwelling of the river; and in thoſe places, if any, that are unfit for paſture or hay, willows or other aquatics might have been planted to great advantage; and thus it might have been of more value perhaps than at preſent, and the interior grounds more effectually ſecured from the ravages occaſioned by a ſudden flood. Notwithſtanding the general indolence ſhewn in moſt parts of the country reſpecting the acquiſition of land by embanking, and the ſeeming averſion that moſt people have to engage in ſuch undertakings, there have been, however, ſome ingenious and enterpriſing projectors, whoſe ideas upon that ſubject have ſoared far beyond the bounds allotted to common underſtandings. From the ſpeculations of ſuch people, the moſt important advantages are ſometimes produced; and ſurely the man who is poſſeſſed of a ſpeculative turn of mind, and who conſiders no obſtacles inſurmountable, is a much more uſeful member of ſociety than he who is perpetually ſtarting difficulties againſt every new project, and is for all things remaining *in ſtatu quo*, that is, for leaving the world as he found it. The idea of embanking Lancaſter ſands, for example, never would have occurred to a torpid genius of this kind. A thouſand difficulties and impoſſibilities would have immediately ſtarted up at ſuch a propoſal, which, to a more expanded mind, appear perfectly practicable to overcome. What then, ſays he, muſt thoſe anti-projectors think, when they are told it is propoſed to exclude the ſea entirely from theſe extenſive ſands, which form a bay, expoſed to a ſouth-weſterly wind, more than ten miles acroſs, containing a ſurface of near forty thouſand acres, and where the tide riſes about fourteen to eighteen feet perpendicular height. Some propoſals and eſtimates have already been made for carrying this project into execution. One very public-ſpirited and enterpriſing gentleman; the late Mr. John Wilkinſon, offered to begin a ſubſcription for that purpoſe, by leading off with the princely ſum of 50,000*l.*; but ſo many unexpected obſtacles have come in the way, by the claims of lords of the manors, and in proportioning the tythes, in the event of acquiring ſo large a tract of country, that few people have on that account choſe to embark their fortunes in this immenſe undertaking, ſeeing that their profits may be liable to ſo many deductions; conſequently nothing concluſive has yet been done in it. Ulverſtone and Duddon ſands, on the ſame coaſt, have alſo been propoſed to be embanked. The latter, over which the writer went with major Gilpin, a gentleman who has paid great attention to that buſineſs, appears to be the moſt practicable. According to his opinion, there might be about nine hundred acres of very good land gained there, by laying out a ſum not much exceeding 20,000*l.*. If, on a correct ſurvey being made by perſons properly ſkilled in ſuch undertakings, ſo valuable an acquiſition is proved to be attainable at ſo ſmall an expence, can there be the leaſt heſitation about immediately commencing a project ſo highly advantageous to that part of the country, and to every individual concerned in it.

That there are many large tracts of land in different parts of the kingdom, both on the ſea-coaſts and on the ſides of lakes and rivers, much more eaſily attainable than Lancaſter ſands, or any of the ſands here noticed, there cannot be the ſmalleſt doubt. It is, therefore, an object worthy of the attention of thoſe who are ſo fortunate as to poſſeſs property in ſuch ſituations, to have it aſcertained by perſons of experience in ſuch matters, how far the acquiſition of additional portions of land may be adequate to the expence which it may be neceſſary to incur in procuring it.

But embankments are important in other views than thoſe of gaining ground by them. When rivers are concerned, one material advantage is the deepening of their courſes, by which veſſels of greater burthen than they admitted formerly may be permitted to trade in them.

And further, as embankments become more frequent on the borders of rivers and ſea ſhores, the intervening diſtances may become a ſort of bays, in which accumulations of ſhells, mud, ſand, gravel, and other matters, may take place by the influx of the tides; and theſe, however difficult they may be at firſt to embank, will in time be as eaſy to perform the work on, as the natural bays and creeks are at this period. In this way many rivers, which in their preſent ſtate are eight or ten miles in width at their junction or influx with the ſea, may in the courſe of years be reduced to leſs than half theſe diſtances. Conſequently ſuch embankments would be equally beneficial to the proprietors of land, and the merchant or manufacturer, as many rivers would become more eaſily navigable, and thoſe obſtacles which interrupt their mouths be wholly removed.

Embanking againſt the Sea.—When encroachments of this nature are to be guarded againſt by embankments, the methods of aſcertaining their proper heights have been ſhewn above. But as new works of this ſort, eſpecially where the banks are large, are liable to ſubſide too much, it may be a proper precaution to take the levels frequently for ſome time after they are completed, in order to guard againſt any miſchief which might ariſe in this way. Where the banks are low this is not, however, ſo neceſſary, as the ſettling is always more or leſs according to their height; in low banks it will of courſe be very little. In the making of ſuch embankments, it is ſcarcely poſſible to lay down any general rule in regard to their ſize or dimenſions, as theſe muſt be directed by ſituation and circumſtances, under the management of an expert engineer. In caſes where the embankment to be formed is to exclude the ſea from a piece of low marſhy ground, over which it only flows at ſpring tides, the work is eaſy and capable of being accompliſhed at no great expence. But where it is intended to reclaim a portion of land which is covered every tide, in ſome bay or creek, or on the ſides or windings of ſome large river in which the tide ebbs and flows, the buſineſs will be in ſome degree more difficult, according to the depth and rapidity of the current of the water. And where it is propoſed to exclude the ſea from ſome expoſed ſituation at the mouth of a river, or in a bay or inlet, which is uncovered every tide, the operation will be the moſt difficult and expenſive of all, according as it is expoſed to prevalent winds, and the depth of the water to be reſiſted. Each of theſe ſituations, therefore, requires a different method of management. The buſineſs of embanking againſt the ſea, when at any conſiderable diſtance within high-water mark, is not only the moſt tedious, but at the ſame time the moſt difficult of any; as when the materials are not very good and the work not well performed, the force of the water at every flowing of the tide will quickly undo all that has been effected, eſpecially if the ſoil be of a ſandy nature, as is often the caſe in ſuch ſituations. If it be a ſtrong clay, as is ſometimes the caſe in marſhy places, there will be the leſs riſk of its being waſhed away. In ſandy ſituations it has been adviſed by ſome to lay bundles of ſtraw or reeds well faſtened down, or any other impediment, to hinder the ſoil from being carried away by the ebbing tide. Where a ſufficient ſupply of good ſtrong turf cannot be had, expedients may be tried: but where ſuch turf can be provided, as is the caſe in moſt marſhy ſituations, and where the embankment required is not to exceed the height of four or five feet, it is beſt to finiſh the ſlope with good turf as expeditiouſly as poſſible, as the work proceeds; that is, ſuppoſing the length of thirty, forty, or fifty feet or yards of it can be completed in a tide; it is better to finiſh that length to its intended height, than to trace out or begin a greater extent than can be finiſhed before the tide returns, by which a great deal of the ſoil might be carried away, and much of the work be demoliſhed, which is not ſo likely to be the caſe when the ſlope is finiſhed. Turf which contains the roots of bent or ruſhes is very good for this uſe. The firſt thing, however, to be done in an embankment of this kind, is to ſtrike out the intended line of it, ſetting out the breadth at the baſe, alſo the width of the excavation or trench to be made in the inſide, from which moſt of the materials that compoſe the bank are to be taken: this trench alſo ſerves as a drain to keep the grounds within dry. There ſhould alſo be trunks or ſluices at different parts of it, to ſhut of themſelves againſt any external water, and to open when the tide ebbs, to let out any water from within. The width of it ſhould be proportioned to the quantity of materials required from it for the raiſing of the embankment, as eight, ten, or fifteen feet wide, and three or four feet deep, leaving a *berme*, or ſpace, between the edge of the trench and the inner bottom of the embankment. If the ſoil be ſtrong, one foot or eighteen inches will be ſufficient for this purpoſe; but if looſe or ſandy, three or four feet at leaſt will be required. The more eaſy and gradual the external ſlope is made, and the leſs ſudden the reſiſtance againſt the ſea will be, as has been ſeen above, and of courſe the embankment be leſs liable to injury; this ſlope ſhould therefore be formed according to the expoſure of it to the winds and tides; nothing, however, can be a greater error than the making it too bold or upright. *Fig.* 1. in the plate, is ſuppoſed to be a ſection of an embankment of this nature, in which the baſe or horizontal line *g h* ſhould at leaſt be three times the perpendicular height *h i*, but *l m*, the inſide ſlope, need not be more than three-fourths of the perpendicular height, that is, nine inches for every foot of riſe. The inſide ſlope ſhould be faced with turf likewiſe, laid greenſide downwards, as in building common ſod walls. Some expert ſodders can finiſh this ſort of work extremely neat by ſetting the ſod on edge, according to the ſlope intended to be given, and with proper mallets and beetles ramming the earth hard behind, which conſolidates the work as it advances, and tends to render it durable. As ſoon as the firſt or lower courſe is finiſhed, the upper edge of the ſods is pared with a ſharp knife quite even, by laying a rule to them, and then they go on with the ſecond courſe, which they finiſh in the ſame manner, and thus proceed until the whole height is completed, which, when properly finiſhed, has a ſmooth beautiful appearance, not a joint between the turfs being ſeen. Where turf is uſed in covering the outſide ſlope, it ſhould all be laid with the graſs uppermoſt, as already noticed, and be well beaten down with a flat ſod-beetle for the purpoſe, and in order the better to ſecure them, it may be proper to drive ſmall ſtakes, about eighteen inches in length, through every ſod. In cutting ſods for this uſe, they ſhould be taken up in a careful manner, and be all traced by a line of the ſame breadth; their edges being cut as even as poſſible, that they may make the cloſer joints, which will tend very much to their ſecurity, until they are grown properly together. In laying the different courſes of ſuch ſods, care ſhould alſo be taken that the joints of the one be covered by the other, in the manner that good brick work is made.

Where it is propoſed to reclaim a piece of land, upon which the ſea ebbs and flows every tide, to a greater depth than in the foregoing caſe, as in a creek, or on the ſide of a large river, a different mode of proceeding muſt be purſued, according to the ſoil, and the nature of the materials to be employed. Where plenty of ſtones can be readily procured, a bank may be formed of them, with a mixture of clay, either by means of land carriage, or which, in ſome inſtances, is better, by conveying them in flat bottomed boats, or punts, and throwing them over-board until the bank is formed. Where ſtones cannot be eaſily had, clay, or other materials proper for the buſineſs, may be thrown in, in ſufficient quantity, in the ſame manner, with perhaps nearly equal ſucceſs. It is ſuppoſed that moſt of the embankments in Holland were formed in this way, the clay dug from the canals being made uſe of for the purpoſe. In either caſe it is requiſite to fix up ſtrong poles before the work is begun, as guides for laying down the materials. Proper ſluices muſt likewiſe be laid in ſuitable directions for taking off the back water when the tide ebbs, under the inſpection of the engineer. Much, in all caſes of this ſort, depends on a ſkilful engineer, who is capable of ſuggeſting and contriving various means of facilitating the buſineſs, and of obviating the difficulties that may ariſe in its execution. A perſon of real genius is often capable, by his different contrivances, of rendering the accompliſhment of a great undertaking comparatively eaſy, which to others would be almoſt impracticable, or carried on at ſuch a heavy expence as to counterbalance the advantages to be drawn from it. In caſes of the kind juſt noticed, he might ſuggeſt the erection of ſtages or platforms, in ſuch a manner as to carry on the work at all times of the tide, which would be an immenſe ſaving, as the delays cauſed by the tides in this ſort of buſineſs are both tedious and expenſive. Waggons might likewiſe be contrived in ſuch a way as to carry on ſuch platforms large quantities of materials at once, which could be eaſily emptied and filled; and at the ſame time be drawn by machinery, in ſuch a manner as to ſave much labour and expence, both in carriage and tide work.

There is another ſpecies of ſea-embankment which is, perhaps, the moſt important of any; as there are few eſtuaries or mouths of rivers in which large tracts of land may not be gained by it. The ſhoals, or flats formed at the entrance of ſuch rivers, are moſtly compoſed of the richeſt materials and moſt fertiliſing particles, brought down from the towns and circumjacent country through which they paſs. Such ſhoals and flats may, therefore, under proper management, be in moſt caſes readily converted into the moſt fertile plains. In ſuch ſituations the firſt object is that of collecting the whole river into one ſtream, and preventing its overſpreading a wider extent than is merely ſufficient for its diſcharge, or it may be better, perhaps, to alter its courſe altogether, and cauſe it to be diſcharged at ſome other outlet. It is in this latter method that it has been propoſed to reclaim the extenſive tract covered by the tides, known by the names of the Lancaſter and Milthrop ſands, as well as thoſe of Ulverſton and Duddon. And the principle on which it is founded is this: it has been found by experience that where the courſe of a river is changed in ſuch a manner as to make it diſcharge itſelf into the ſea at a different place to that where it did before, the former place will, in a few years, by the continued accumulation of ſand and mud brought in every tide, be ſo choaked up and raiſed above its former level, as to form of itſelf, in the courſe of time, a bank that, with a very little aſſiſtance, will quite exclude the ſea; for as the current of the river before carried away all that ſediment which the motion of the waves naturally ſtirred up, from its being now removed, it is obvious that all or moſt of the muddineſs will not only be carried further up the old channel of the river, but a great part of it be depoſited there as the tide recedes. It has been found that in ſpring-tides and particular winds, this ſediment is depoſited in larger quantities than at other times, and the writer has been informed that a gentleman in Lancaſhire, who has gained ſome land in this way, has found, on making a perpendicular cut in the ground ſo recovered, that the different layers were ſo diſtinct, he could readily diſtinguiſh thoſe made at ſpring-tides from the reſt. This curious fact is well deſerving of the attention of all thoſe who have lands ſituated at the mouths of rivers, as there may in many ſuch ſituations be conſiderable tracts gained in this manner at a very light expence. But though this fact may exiſt in ſome places, as has been proved by experience, nevertheleſs it is ſuppoſed that the effect cannot be the ſame in all ſituations. Where there is a great extent of flat or muddy ſhores, the motion of the waves will no doubt ſtir up the mud or ſand, and carry great quantities of them along with the current on the flowing of the tide, and when the tide ebbs, though ſome of the lighter particles will be carried away again, yet it is reaſonable to ſuppoſe the heavier ones will be left behind. If the ſhores are bold and rocky, except juſt near the entrance of the river, there will be the leſs of this mud; but on ſuch ſhores there can, indeed, be little or no occaſion for embanking, unleſs perhaps in ſome creeks, narrow at the entrance and ſpreading out wide above. If the ſea were excluded from ſuch creeks, a great deal of land might probably be gained.

It was found, on having a ſurvey made of the Lancaſter ſands, and of the propoſed alteration of the courſe of the river Kent, that the length of the cut, neceſſary to be made from a little below Dalham Tower to the river Lune, was 21,340 yards, or twelve miles and one furlong. This cut was propoſed to be about thirty-four yards wide, and four yards of average depth, making in the whole an excavation of 2,902,240 cubic yards: the expence of excavating which, at 4½*d.* per yard, would amount to 54,417*l.* But perhaps this eſtimate is rather under-rated at 4½*d.* the cubic yard; but on the contrary the average depth of the excavation is preſumed to be conſiderably over-rated at four yards, as a great part of the depth neceſſary may be made up by the ſoil thrown out; conſequently whatever is made up cannot be conſidered as a part of the excavation; beſides if the river Kent, Lindale pool, and the other ſtreams propoſed to be taken into this new cut, require, when united, a ſpace or channel to contain them whoſe tranſverſe ſection is 136 yards ſuperficial, it would be much leſs expenſive, it is ſuppoſed, to add eleven yards to the breadth, and to take one from the depth propoſed, unleſs it be neceſſary, from the level of the bottom of the river, to make the bottom of the new cut of a certain ſtated depth. The whole expence of completing this great undertaking has been eſtimated at only 150,000*l.*, and in the opinion of ſome perſons fifty, or perhaps ſixty thouſand leſs might be ſufficient. It is, however, apprehended, that in this eſtimate there has been no allowance made for the neceſſary buildings on ſo extenſive a tract, or for incloſing and draining; all which, as well as the intereſt of money laid out before any return can be expected, ſhould be conſidered in calculating the expence of bringing into improvement ſuch lands as theſe. And further, there are other eſtimates to be made for neceſſary buildings in its cultivation; beſides in the eſtimates which have been made, it is taken for granted, that if the freſh water be conducted another way, as propoſed, in a few years the ſea will completely exclude itſelf from this extenſive tract of land, and conſequently no allowance whatever is made for any ſort of embankment acroſs thoſe ſands. Experience has not, however, ſo ſufficiently ſhewn the certainty of this method of gaining land from the ſea, as to place that ſort of confidence in it that is requiſite. If, indeed, it could be fully depended on, the ſpeculation would be admirable, as well as the advantage and profits ariſing from ſuch an acquiſition immenſe; but if after laying out nearly perhaps 200,000*l.* in altering the courſe of the rivers, &c. it ſhould be found that the ſea left little or nothing behind, or if it did leave ſome at one time, but carried it all away at another, in what predicament muſt thoſe perſons concerned find themſelves? They muſt either loſe the whole of the money laid out, or they muſt expend at leaſt 200,000*l.* more, perhaps, in performing what they had ſo implicitly truſted to the operation of the ſea. If, however, it were certain that even a fiftieth part of an inch was depoſited every tide, the ſucceſs of the undertaking would be unqueſtionable, and a concern in it highly profitable, as in very little more than eight years ten feet of perpendicular height would be raiſed, and it would be an eaſy taſk to accompliſh the reſt of the buſineſs.

The Duddon ſands are another tract, it is ſuppoſed, where great improvement is capable of being effected at a very eaſy rate, when compared with that juſt noticed. In the preſent ſtate a great deal of land, that is capable of producing the beſt crops, is often overflown and rendered ſo wet and marſhy as to be of little or no value. While, by altering the courſe of that river, and bringing it farther north on the low marſhy ground, it would ſeem from viewing it, without actually taking the levels, that not only the whole of the ground might be completely drained, but a conſiderable tract of lands be reclaimed. The making of the new channel for the river ſeems perfectly eaſy and practicable, the ground being nearly level, with the exception of a ſmall riſe at one place, all the way from where the new cut would begin, which is about two hundred yards above Duddon bridge to Havering pool; where it would empty itſelf into the ſea. The length of this cut would therefore be about ſix miles, which ought to be made navigable all the way, with a lock near the ſea, and a baſin with proper landing places for delivering goods. The quantity of land that might be thus gained, including the ſands and marſhy ground on each ſide, would, it is ſuppoſed, on the authority of major Gilpin, be about 2000 acres, and the whole expence under 20,000*l.* The land, too, has every appearance of becoming one of the moſt fertile kind; in proof of which a farmer, who ſome years ago gained a few acres of it by embanking them againſt the ſea, found that it produced the beſt crops of all kinds, even with little or no manure. So large a tract of valuable land, capable of being gained at ſo very trifling an expence, is therefore an object highly worthy of attention, not only as a profitable concern, but on account of many other advantages that would ariſe from it. It is, therefore, ſurpriſing, that the proprietors in the vicinity or other enterpriſing individuals have not long ago taken the neceſſary ſteps to reclaim theſe ſands. The execution of theſe projects would, it is conceived, be attended with the moſt beneficial effects to a very extenſive tract of country, and be ultimately felt in ſome meaſure by the nation at large. There would not merely be an addition of territory larger than either of the iſlands of Guernſey or Jerſey, but it would tend to improve at leaſt four times that extent of the interior country. A ſafe and ſpeedy communication would be opened between the towns of Lancaſter, Whitehaven, Ulverſton, Ravenglaſs, Dalton, Bootle, Egremont, &c. and all the intermediate country, inſtead of a mountainous and very circuitous route, or a precarious and dangerous paſſage over Lancaſter ſands, in croſſing which accidents are not unfrequent. Independently of the advantage ariſing from the produce of the lands to be acquired, the produce of the interior part of the country, which in many places is extremely fertile and well cultivated, would be eaſily brought to market; whereas it is at preſent, with the utmoſt difficulty and inconvenience, that any commodity whatever can be tranſported over theſe dangerous ſands and almoſt inacceſſible mountains. By diverting the river Duddon into the navigable cut propoſed, it would yield the moſt important advantages to the town of Broughton and all the back country, by facilitating the importation of coal, lime, and other produce of every kind, and the exportation of ſlate, iron, and other productions of the country. But though different public-ſpirited individuals have been active in forwarding theſe highly laudable and important undertakings, the oppoſition which has been given by the proprietors of ſome trifling fiſheries, who were offered a full indemnification, and from ſome lords of manors, who would neither contribute towards ſuch improvements, nor relinquiſh any part of their claims to the ground when improved, they have been for ſome time in a great meaſure in a dormant ſtate. It is hoped, however, that in theſe enlightened times, when the ſpirit for improvements of this kind ſhould be particularly arouſed, theſe important and neceſſary projects may be again taken up in a ſerious and effectual manner, and that every obſtacle which may ſtand in the way of their completion may be ſpeedily removed. And that if the attempt of re-claiming Lancaſter ſands ſhould be conſidered as a too expenſive and too mighty undertaking to begin with, an experiment may be made on Duddon ſands, where the money propoſed to be expended is comparatively trifling, and where, if the ſcheme ſhould ſucceed, there could not be the ſmalleſt reaſon for doubting the ſucceſs of the other.

In the marſhland diſtrict of the county of Norfolk, lying between the rivers Wyn and Ouze, immenſe tracts of the moſt rich land, ſuch as is compoſed of the muddy depoſitions left by the tides and floods, which is there called ſilting, have been obtained by means of embanking. In this important buſineſs, the late count Bentinck, and his ſon, the preſent poſſeſſor, have been largely concerned. This kind of work has ſometimes been undertaken by the tenants on a new piece of marſh, in conſideration of having the land free for twenty-one years. But in theſe caſes the banks have often been very imperfectly made, not having coſt more than forty ſhillings a rod. And thoſe which were conſtructed by the landlords were indeed frequently but little better, being moſtly deficient in not having ſlope enough given them towards the water. Count Bentinck therefore laid his out upon a ſcale never practiſed in that part of the iſland before, and his ſucceſſor has ſtill far exceeded it. That planned by the former extends about four miles, and has added to the old eſtates not leſs than a thouſand acres. The baſe of the embankment, in this caſe, is about fifty feet, the ſlope to the ſea thirty-ſix feet, forming an angle, it is ſuppoſed, of about twenty-five or thirty degrees. The crown is four feet in width, and the ſlope to the fields ſeventeen feet, in an angle ſuppoſed of about fifty degrees; the ſlope towards the ſea being very neatly turfed over. The firſt expence incurred in forming this bank was four pounds per rod, but a very high tide coming before it was finiſhed, not only made ſeveral breaches, but occaſioned an additional height and ſlope to be given to ſeveral different parts, in order to bring it to the dimenſions mentioned above, all of which made the groſs expence to amount to about five pounds the rod. The whole coſt was ſomething more than 5000 *l.* The expence of the houſes, farm buildings, and other things, was about as much more, for five new farms, which was a greater expence than was neceſſary, as the land would have let as well in two or three as five farms. Suppoſing, therefore, the expence at 10,000 *l.* and the new rental as 1000 *l.* a-year, it is juſt ten *per cent.* for the capital laid out. The expence here, however, ſeems to have run too high, when the neceſſary repairs of the bank are taken into the account. The repreſentation, given at *fig.* 11. in the plate, fully explains the nature of the embankment formed in this caſe.

In another new embankment, in which two hundred and ſeventy-three acres of marſh land, and eighteen of bank were gained, the men were paid four ſhillings and ſix-pence a floor of four hundred cubical feet, finding wheeling planks, barrows, truſſels, &c. When it is thus formed, the front ſlope is ſodded, for which they are paid in addition four ſhillings a floor of four hundred ſquare feet, earning from five ſhillings and ſix-pence to ſeven ſhillings a day, and there is ſome little further expence neceſſary for beating it down in a firm manner. The whole of the expence of the bank, ſluice, and every thing elſe, was about 3300 *l.* The land was immediately offered to be rented at four pounds an acre for four years, or three pounds an acre for ſix years; which, in the former caſe, would amount to 4368 *l.* in that length of time, or one thouſand guineas more than the whole of the capital laid out in the undertaking.

On this coaſt the operation of *ſilting* up, or raiſing the ſurface of the marſh land by the repeated depoſitions of muddy matters from the ſea, is performed in a more rapid manner than in many others; and the little hollows and creeks are found from experience to ſilt up much faſter where the tide waters are ſpeedily taken off by proper cuts and channels formed for the purpoſe, than where the contrary is the caſe.

Embanking againſt Rivers.—The embankments againſt rivers may be divided into two kinds; namely, ſuch as are for preventing their encroaching on the adjacent lands, and for protecting thoſe lands and the neighbouring level country from being overflown, when the water riſes above its ordinary level. It may be remarked, that where the courſe of a river is a ſtraight line, or nearly ſo, it hardly ever makes any encroachment upon its banks, unleſs, perhaps, in very large rivers when they riſe above their common level, either owing to an increaſe in the waters, or to their being, in ſome degree, affected by the tides. In either caſe, the waves occaſioned by a ſtrong wind, where the river is wide, will moulder away the banks on that ſide upon which it blows, unleſs prevented in proper time. This may be done either by ſecuring the bank properly with ſtones, or by driving a row of long piles pretty cloſe together at a little diſtance from the ſhore, the piles being of ſuch a length, and ſo driven, that their tops may be always above the higheſt riſe of the water. It is ſurpriſing the effect that piles driven in this manner have in reſiſting the power of the waves in ſuch ſituations.

Some years ago, when Mr. Beatſon was on duty as an engineer at a fort near Portſmouth, built on a point of land much expoſed to the ſea, the waves made ſuch havock, that the walls on that ſide were conſtantly giving way, although built in the moſt ſubſtantial manner, and having bulwarks of large heavy ſtone beſides to protect the foundation: however, all would not do; thoſe bulwarks were ſoon knocked to pieces, and ſeveral times the wall itſelf. At length it was propoſed to drive a number of piles at about forty to fifty yards from the fort. Theſe piles were twelve or fifteen inches in diameter, and driven about one diameter from each other nearly in a ſtraight line, parallel to the wall where the waves did ſo much damage. They were driven into the ground with a pile engine till perfectly firm, perhaps eight or nine feet deep, and about two feet of the top of them left above the level of high-water mark. After this was done the wall received no farther injury, the ſpace between the piles and the fort being always perfectly ſmooth, however tempeſtuous the waves might be without. The ſame ſimple method might, it is ſuppoſed, ſometimes, perhaps, protect the banks of large rivers, if expoſed to the waves, when other methods might fail.

But it is ſuggeſted, that the moſt common courſe of rivers encroaching on their banks, is the reſiſtance occaſioned by a ſudden bend. In flat countries, apt ſometimes to be overflown, where there are any ſuch bends or windings in the rivers, it would be of great advantage to ſtraighten the courſe as much as poſſible, for, as every impediment or obſtruction will naturally cauſe the water to riſe higher than it otherwiſe would do, and as ſuch bends have that effect, conſequently, in the time of a flood the waters will overflow a greater extent of country, and to a greater depth than if the river had a free and uninterrupted courſe ſtraight forward.

If the windings of the river cannot be altered, and encroachments are making on ſome part of the banks, it muſt firſt be conſidered, whether the force of the water can be driven to another place where no injury can be done. If, for example, a river is encroaching on its banks, at *x*, *fig.* 2. a jutty of ſtone, a little way up the river in the direction *y z*, would throw off the current towards *w*, and might totally prevent any further encroachment. On the river Nith, in Dumfriesſhire, it is ſtated that a good deal has been done in this way by Mr. Millar of Dalſwinton, a gentleman of the moſt enterpriſing genius and moſt liberal mind, who has paid more attention, and laid out more money in making important and uſeful experiments, than almoſt any other private individual. The courſe of the river, where Mr. Millar has been carrying on his operations, is ſaid to be nearly as ſhewn at *fig.* 3. by *r s t u*; at *t*, it was encroaching moſt rapidly, and ſeemed inclined to take a new courſe towards *v*, which would have deſtroyed ſome very fine land, and done a great deal of miſchief in that part of the country. To prevent this, Mr. Millar made a large cut about 400 yards in length from *w* to *r*, and threw in a great quantity of ſtones quite acroſs the river at *s*, to direct its courſe in a ſtraight line from *r* to *w*. This had, in a great meaſure, the deſired effect, by totally preventing its progreſs at *t*, but now it began to encroach on its banks at *u*. He at firſt endeavoured to prevent this by driving in at a conſiderable expence a number of piles at a little diſtance from the bank, and wattled them with willow branches, &c. thinking thereby to protect the bank. The piles were drove in with heavy mallets, apparently firm into the ground; they continued ſo for ſome months, till a heavy fall of rain came on, which ſwelled the river, undermined the piles, and carried them all away. But, indeed, it is in vain to think of piles doing any good in ſuch a ſituation, unleſs firmly driven in by a pile engine; for it is not poſſible to drive them in properly with mallets; this muſt have been the cauſe of their giving way ſo ſoon. The piles not ſucceeding, Mr. Millar was reſolved to try another plan; ſeveral of his adjacent fields being covered with an immenſe quantity of ſtones, he ordered them to be gathered and thrown into the river, ſo as to form a jutty at *x*, a little way above the injured bank. Being obliged to go from home about that time, and to leave the execution of the work to ſome country people, they carried out this jutty too much at right angles to the ſtream. It had not, therefore, the deſired effect, but rather made the matter worſe than before; for, if a jutty is carried out at right angles, as at *a* in *fig.* 4, the current will be forced from *a* to the oppoſite ſide of the river at *b*, and from thence it will rebound towards *c*, more violently than it did before. But if a jutty be placed obliquely, as at *d*, it will force the current gradually towards *e*, in which poſition one jutty may do more good than ſeveral placed improperly at right angles. Mr. Millar was, therefore, under the neceſſity of making other jutties in this way, and has now the ſatisfaction to find that they anſwered the purpoſe intended. Theſe he made laterally formed a ſort of convex ſlope, the convexity being parallel to the current. Strong planks were alſo firmly ſet on edge among the ſtones, their ends pointing towards the river, ſo that if ever any current came ſo rapidly as to move any of the ſtones, it muſt move them all in a body the whole length of the plank. Perhaps this precaution was unneceſſary; for although ſtones are thrown into a river looſe in this manner, the fluſh ſand, &c. that come down the river will ſoon fill up all the cavities, and render it as firm and ſolid as a regular built wall. Mr. Beatſon has been the more particular in this deſcription, he ſays, in order to ſhew the errors that Mr. Millar at firſt fell into, and the great expence they occaſioned, whereas, had he been on the ſpot himſelf, and got the work executed as he intended, it would have ſaved a great deal of unneceſſary labour as well as money.

It is ſtated by the ſame writer, that the next ſort of embankments againſt rivers, are thoſe to prevent them overflowing their banks, and inundating large tracts of country. This may be conſidered as the ſimpleſt and eaſieſt of all ſorts of embanking, if judiciouſly executed. It is, therefore, the more inexcuſable to ſee, in ſome places, extenſive tracts of the richeſt meadows completely overflown by every flood for want of them.

Two ordinary ſized rivers riſe no more even in the greateſt flood than five or ſix feet above their common level, unleſs when they meet with ſome conſiderable interruption or confinement in their courſe. But if interrupted or confined, they will riſe twenty feet or more, as is the caſe with ſome parts of the river Merſey already mentioned. If, for example, a given quantity of water is ſix feet deep, when running over a ſpace twenty feet wide, it is clear, if that ſpace was only made ten feet wide, the water would riſe to twelve feet, and if it were made forty feet wide, the ſame quantity of water would only riſe to the height of three feet.

It is, therefore, of great conſequence, in preventing inundations, to give the river as much width as poſſible, by widening every narrow place. All kinds of obſtructions ſhould alſo be removed, whether occaſioned by windings, ſhoals, ſtones, trees, buſhes, or any thing elſe. In ſome caſes this may even preclude the neceſſity of embanking; but where embanking is neceſſary, let the banks by all means be at a ſufficient diſtance from each other, to contain with eaſe, between them, the largeſt contents of the river in great floods. The diſtance and height of the banks may eaſily be aſcertained by meaſuring a ſection of the river when at its higheſt, or when the flood mark is viſible. By not attending to this, a great deal of money has been thrown away on the embankments on the river Merſey, and after all they do not effectually anſwer the intended purpoſe; a great part of the country being ſtill overflown every time the river riſes to any conſiderable height.

Where a ſufficient diſtance is allowed between the embankments their height need not exceed from four to ſix feet. If irremovable obſtacles are in the way, which cauſe the river to riſe higher, the banks muſt be higher in proportion. In either caſe, however, the ſlope of theſe kinds of banks on each ſide may be equal to its perpendicular height, and the breadth on the top about one-third of that height, which, ſuppoſing the bank ſix feet high, the baſe would be fourteen feet, and the breadth of the top two feet, as ſhewn at *fig.* 5. in the plate.

The materials for making theſe banks ſhould be taken as much as poſſible from the ſides of the river, which will have the double effect of widening the river and forming the embankments; and there ſhould be a trench on the inſide (from which materials may alſo be got) with ſome ſluices, as formerly directed, to drain off any water from within; alſo ſluices to let in water from the river, if required, which would very much fertilize the meadows if properly laid out for that purpoſe.

Such farms as are ſituated on the borders of rivers are frequently, it was obſerved by a late writer, liable to much injury and inconvenience from them; 1ſt. From part of the ſoil being carried away in times of flood. 2d. From their overflowing their banks. 3d. From their flowing back in times of flood into the channels of the rivulets and ſtreams that conduct the water from the more elevated and diſtant grounds

grounds to the rivers, whereby theſe rivulets and ſtreams are made alſo to overflow their banks.

In reſpect to the firſt, the danger of the ſoil being carried away in time of floods, it is increaſed or decreaſed according to circumſtances, as the form of the banks, the nature of the ſoil, the rapidity of the river, and the quantity of water that lodges on the margins of the banks, or falls over them into the river. Where the banks of a river are perpendicular, eſpecially if the ſoil be of a rich mouldering nature, the danger of part of them being carried away by floods is much greater than where they ſlope gently from the ſurface of the field to the bed of the river, as has been already fully ſeen.

Where that is not the caſe naturally, they ought to be moulded into that form by art; as when a river, in place of being confined in its progreſs, has a power of efflux and reflux, the damage to be apprehended is inconſiderable, compared with what is likely to happen when, being reſtrained within too narrow limits, it is conſtantly ſtruggling for an extenſion of ſpace. Where the ſoil is rich free mould, and the under ſtratum oppoſite to the greateſt force of the water, ſand, or gravel, this ſtruggle never fails to be attended with bad conſequences. If the ſoil and ſubſoil be one entire maſs of clay or ſtrong loam, and the current of the river does not preſs more upon one part than another, a moſt ſubſtantial improvement may be effected by ſloping the bank, ſo that the declivity may be one foot in three or four from the ſurface of the field to the bed of the river. This ſome may object to, as ſacrificing a certain portion of valuable land; but it ſhould rather, it is thought, be conſidered as a premium paid for the inſurance of the remainder, than as a total loſs. If gravel, mixed with ſmall ſtones, can be conveniently procured, ſpreading theſe materials on the ſloping bank to the depth of eight or ten inches, and till beyond the flowings of the river, will prove a good ſecurity againſt further damage; and if the bank be planted thick with any ſort of willow, eſpecially the Dutch willow, it will in a ſhort time become an impenetrable fence, while the annual cuttings of wood will ſoon be equal to the heritable value of the land thus apparently ſacrificed. Where no gravel can be procured, the new ſloped bank ſhould be immediately covered with well ſwarded turf, which ſhould be preſſed down as hard as poſſible, either with the back of a ſpade, or with wooden mallets. If this be done in the beginning of ſummer, and willows be planted the following autumn, the improvement, it is ſuppoſed, will be both effectual and permanent. In caſe the river run with extraordinary violence againſt any one particular part of the bank, it may be neceſſary to make a fence or bulwark of ſtone in the front of that place; the beſt way of doing which, is, in place of building a wall, to drop the ſtones in a careleſs manner, but ſo as they may lie cloſe together on the ſloped bank, as already ſuggeſted.

This is a much more ſecure mode of fencing, if the bank be made with ſufficient declivity, than any ſtone wall that ever was built for the purpoſe, and while it is the moſt ſecure, it is alſo the leaſt expenſive; but care ſhould be taken to lay the ſtones all the way from the bed of the river, till conſiderably beyond where the river flows in common. Where the ſoil is of a ſtrong adheſive nature, and the under ſtratum is ſand or a pebbly gravel, it becomes in a much greater degree neceſſary to ſlope the banks. The water, when ruſhing violently along, has a powerful effect in undermining the bank, and carrying off thoſe incoherent ſubſtances; ſo that the ſoil, having nothing to ſupport it, naturally gives way, and frequently in ſuch quantities as to occaſion very ſerious loſſes both to proprietors and tenants. In all ſuch caſes, the ſlope ſhould be made much more gradual than where the ſoil and ſubſoil is of the ſame quality, and ſuch as will nouriſh aquatic plants. The banks, having been ſloped according as circumſtances require, a thick coat of gravel, mixed with ſmall ſtones, where ſuch can be procured, ſhould be laid on ſo as to form a kind of natural beach, over which the river, when in flood, may have power to extend itſelf at pleaſure. Should it be difficult or impoſſible to procure ſuch materials as are proper for forming this beſt of all defences, ſtrong thick ſods ſhould be placed on the ſurface in the manner before directed, which, if laid on in ſpring, or early in ſummer, will have time to unite, and to become one compact body before the autumnal floods (which are thoſe whence the greateſt danger is to be expected) begin to flow. If the ſubſoil be of ſuch a nature as that willows will not grow, ſuch ſods as are full of the roots of ruſhes ſhould be made choice of in preference to all others; as where theſe plants thrive and ſpread over the ſurface, it becomes in a great degree impenetrable by water, even in great floods, and when the river runs with conſiderable violence and rapidity.

The directions above given will, it is ſuppoſed, be found more or leſs practicable and uſeful according as the river on ordinary occaſions runs with greater or leſs rapidity. In level, or nearly level diſtricts, all that is neceſſary is to ſecure full ſcope for the rivers to overflow their uſual bounds without interruption; when that is ſecured by either of the methods before mentioned, floods, unleſs very violent, ſeldom do any material damage to the banks of rivers in ſuch ſituations. It becomes in many caſes extremely difficult to fence rapid running rivers in ſuch a manner as to prevent part of the banks from being carried away by inundation. Sloping the banks would be attended with no good conſequences. Even ſtrong bulwarks made of ſtone are often ſwept away by the overpowering flood. A method has, however, been ſuggeſted, of fencing the ſides of a rapid running river, which has been practiſed with ſucceſs, after ſeveral other attempts had failed; it is by means of a ſort of large baſkets, provincially termed creels, formed of hazle, willow, &c. into a kind of open net work, which being placed along the bottom of the banks, were filled with ſtones. This is a very ſimple, and by no means an expenſive expedient; and as theſe baſkets may be made to contain two or three tons of ſtone, it can only be on few occaſions, and in very particular ſituations, that a baſket, containing ſuch a weight, can be diſplaced or carried away. Such a mode of fencing as this, it is imagined, would prove effectual in many parts of Scotland and Wales, where the rivers run with uncommon rapidity. Owing to inattention, or rather to not being aware of the conſequences, much damage is often done to the banks of rivers in level diſtricts, eſpecially if the banks be perpendicular, and of a conſiderable height, by allowing the land floods to fall over them into the river. As the water from the furrows approaches the bank, it is frequently ſtopped in the furrow of the head ridge, which becomes for a time a kind of reſervoir; the conſequence of which is, that a conſiderable proportion of water ſinks and filters through the earth, which being thus ſoftened and ſwelled, is more eaſily undermined and carried off by the river. Sometimes little cuts or openings are made for the furrows acroſs the head ridge, for the purpoſe of conducting the rain water into the river; here, again, the conſequences are equally bad. Whoever will examine the bank of a river where this mode of management is adopted, and it is very common, will obſerve, that at every one of theſe cuts or openings a little creek is formed, in conſequence of the bank having been more ſoftened, and by that means having become a more eaſy prey to the river when in flood. To prevent theſe evils, it is neceſſary, beſides ſloping the banks, to devote a part of the lands adjoining to the breadth of twenty or thirty yards, for inſtance, either to paſturage or the growth of trees, and to form a drain at a proper diſtance from, and parallel to the bank, for the purpoſe of collecting and carrying off the water from the furrows. Were this done, and were the water from this drain conducted into the river by conduits formed a little above its ordinary level; much land, which is annually loſt by neglecting this ſimple precaution, would be ſaved, and preſerved in a proper ſtate.

In the ſecond caſe it is evident that injuries, although of another nature, are often ſuſtained by farmers, from rivers overflowing their banks. Sometimes the farmer is prevented from ſowing his field; at other times the crops of grain and graſs are greatly injured, by being covered for a conſiderable time with water; and at others again, the whole produce of the year, the hay and corn crops are ſwept away. To prevent evils ſo complicated, and ſo ſerious in their nature, is certainly the buſineſs of every man, who, from the ſituation of his farm, has reaſon to apprehend, that without uſing proper precautions, he may be ſubjected to ſuch viſitations. Theſe damages can only happen in level tracts, where the banks of the rivers are low, and where the courſe is not of ſufficient breadth to contain the water in time of flood. Some people, although very improperly, raiſe mounds of earth cloſe to the top of the bank, and of a height exceeding that to which the river can be expected at any time to riſe. Theſe mounds, from being placed ſo near the river, are unable to reſiſt the preſſure of the water, and by giving way, frequently admit a current into the fields, which proves much more injurious in its courſe than if no mound whatever had been erected. Were a mound of earth, formed on the ſide of the drain, propoſed to be made for carrying off the land water, and were that mound well ſloped on the ſide towards the river, it would be the moſt ſecure and effectual guard againſt rivers doing injury to the adjoining lands, of any that could be adopted. By theſe mounds being placed at a diſtance from the river, the force of the ſtream would be much leſſened, and the natural boundaries of the rivers greatly enlarged, as in proportion as the mounds are removed from the centre of the current of the river, in like proportion will they become more ſecure, as being leſs liable to violent preſſure. The propriety of erecting theſe mounds at a proper diſtance muſt, therefore, be ſufficiently evident, as when mounds are erected near the top of the bank, which can only be owing to ill-judged parſimony, they form as it were a part of the bank, and are liable to be undermined and ſwept away. Whereas, when they are placed at the diſtance of twenty, thirty, or forty yards, they ſerve rather as a boundary to confine the overflowing waters which glides along the bottom, than as a barrier to prevent the encroachments of an impetuous river during the time of floods.

In regard to the third caſe it is obſerved, that farmers who poſſeſs lands in low ſituations often ſuſtain damage from rivers, in time of flood, by their flowing back into the channels of the rivulets and ſtreams that conduct the water from the more diſtant and elevated grounds to the rivers, whereby theſe rivulets and ſtreams are made alſo to overflow their banks.

The only precaution that can be adopted, in ſuch a caſe, or at leaſt the one which appears to have the greateſt probability of anſwering the purpoſe, is to erect mounds at a diſtance from the banks, and of a ſize proportioned to the quantity of water which, from the cauſe now mentioned, may be ſuppoſed at any time to ſtagnate in theſe channels. This may be done at a very trifling expence either in money or land. If the proprietors do not chooſe to ornament the county and improve their own eſtates, by planting trees on the borders of the rivulets and ſtreams, the farmers may ſo conſtruct theſe mounds, as that they may become fences to their arable fields, while that portion of the farm, neceſſarily and properly cut off for the protection of the remainder, may be devoted to paſturage.

Several different embankments of a ſucceſsful kind have been lately effected in the northern parts of the kingdom. An important work of this nature has been executed on the eſtate of lord Galloway, ſituated on the mouth of the river Cree, near Cree town, by his lordſhip's tenant, Mr. Thomas Hannay, who ſtates in the third volume of the "Farmer's Magazine," that he "entered to the farm about four years ago, on a leaſe of twenty-one years, and his life; at which time upwards of 100 Scottiſh ſtatute acres were regularly flooded by the higheſt ſpring-tides, excepting about three months in ſummer, when the tides were lower. They were ſeldom, however, covered above the deepneſs of one or two feet, and never above four or five. Eighty acres of the above conſiſted of a rich ſea marſh, or *ings*, as they call them there, almoſt a true level, excepting where hollows were formed by the egreſs and regreſs of the tides, and the paſſage of freſh water from the higher grounds; and about four or five acres, which were about ſixteen inches lower, being a younger marſh, and nothing but what they call ink-graſs growing upon it (as he is no botaniſt he can give it no other name); other graſſes, ſuch as clover, rib-graſs, &c. grew on the reſt of the marſh, forming a very beautiful cloſe cover in the ſummer. The other twenty acres were at an average about eighteen inches higher; conſequently, the ſea did not cover them ſo often. It had formerly been ploughed, but not for about twenty years paſt. Laſt time it was in corn, it was flooded immediately after being ſown, which rendered the crop almoſt entirely uſeleſs, and deterred former tenants from ploughing it again. He began to bank this field in the autumn of the year 1798, by making a dike along the ſide oppoſite to the river, in a direct line facing the eaſt. This dike was made, at an average, about three feet and a half high, and ſix feet broad at bottom, and twenty inches at top, built after the ſame manner with that mentioned below. "He incloſed, along with the ſaid fields," he ſays, "four acres of the marſh adjoining, by making a dike five feet high, and five feet in bottom almoſt wholly of ſolid ſeals or ſods, with a very little ſtuff, properly beat, in the heart of it, which makes an excellent fence, and promiſes to be a very durable one. This dike, together with two ſmall drains, one on each ſide of it, about two feet deep, coſt 3*d.* per yard. He has been more particular in mentioning this dike here, he ſays, as the diviſion dikes of the whole marſh, which is now divided into four parts, are all built after the ſame manner, only that there is no looſe ſtuff in the heart of ſome of them, but all of ſolid ſeal, jointed like brick, as may be ſeen at *fig.* 6, which repreſents an end-view, or ſection of it. This dike, meant as a permanent fence, anſwered as a temporary bank, and enabled him to plough that field in ſpring 1799, although the bank round the whole marſh was not finiſhed till the winter following." He "ſowed oats on this field, and, conſidering the badneſs of the ſeaſon, had a very good crop; particularly ſo on that part which had not been ploughed formerly. On further conſideration, he altered the plan of the bank round the marſh, (which extends in a circular direction facing the north,) by making it, at an average, about four feet and a half high, and allowing about two feet in the baſe for one in height, as at *fig.* 7, where *a b c* repreſent an end-view, or ſection of it, every ſmall ſpan repreſenting the ſection of a feal or ſod; *ab* ſhews the inſide of the bank, with the green ſide of the feal down; *bc* the baſe; *a c* the ſide next the water, with the green ſide of the feal out, (which adds greatly both to the ſtrength and beauty of the bank); and *d* the heart of the dike, made up with ſtuff properly compreſſed with a rammer. The ſtuff was taken from a ditch in the inſide of the bank, leaving a caſement of a foot, which ought to have been three at leaſt; and, where the ground is of a ſandy nature, more; as the freſh water, running in the inſide, was likely to undermine the bank, had he not prevented it, by cutting a new drain, and filling the old one with the ſtuff caſt from it. The only creek worth noticing, through which the bank paſſed, was was one about forty feet wide, and nine feet deep, in the bottom of which a wooden pipe, with a ſtopper, was laid through the bank. No tide offered the ſmalleſt injury to the bank till January laſt, when there was one of the higheſt ever remembered by the oldeſt inhabitant, which broke it at this creek. This, he thinks, was owing to the wooden pipe not being made ſtrong enough, as the weight of the ſtuff and water preſſed in the ſides of it, and thereby admitted the water below. The tide made alſo three ſmall breaches in that part of the bank, which was built after the firſt manner; but in the part made after the manner repreſented in the figure, no breach took place, though it was rather lower than the other part. There are now about fifty acres of the ſame kind of marſh land adjoining his; and alſo about 100 acres on the other ſide of the river, banked in, all neraly in the ſame manner as repreſented in the figure. The bank on the farm adjoining his, ſuffered little from the high tide; but the one on the other ſide of the river was made almoſt a complete wreck, owing to its lying quite oppoſite to the ſouth-weſt winds, which always ſend up the higheſt tides; but this is not the caſe on this ſide, theſe winds blowing right over their bank. In his opinion, the bank on the other ſide of the river, in order to be durable, would require to be thirty feet broad, and eight feet high, covered with feals, with the green ſide out; and that no ſtuff ſhould be lifted within ſix or ſeven feet of it, the ground being of a ſandy nature. It might be made after the form ſhewn at *fig.* 8. He has now got the breaches in his bank made up, and has begun to give the whole a complete repair, by adding, at an average, fifteen inches to its height, and two feet of baſe for each foot in height. The whole bank is about 1500 yards in length, and, when the repairs are completed, will altogether coſt him betwixt 80 and 90*l.*

"In the year 1800, he ploughed another field, he ſays, of about twenty-ſix acres of the marſh, beſides the one formerly mentioned, on which he had an excellent crop of oats, thought by many to be the beſt they had ever ſeen. Laſt year, he had the ſame field, part in oats, and part in wheat: the wheat was a very good crop; and the oats, which were of the Poliſh kind, far exceeded the crop of the former year. Laſt ſummer, he levelled the old ridges of the firſt-mentioned field, all by the ſpade; gave it a complete ſummer-fallow; ſhelled and dunged it well; had part ſown with wheat, part with potatoe-oats, and all with graſs-ſeeds. The other field is ſown, part with wheat, and part with beans drilled; and, what is very ſurpriſing, he ſays, although the wheat was covered ſeveral times by the ſalt water, when the bank was broke, ſome of it to the depth of three feet, yet it is all looking well. The whole marſh is, he ſays, this year, under the plough. It may be worthy of obſervation, that the four or five acres, which he mentioned as being a younger marſh, harrowed eaſier than the reſt, and produced as good, if not better, crops."

Another improvement of the ſame nature has been accompliſhed, on what in Scotland is termed Carſe land, on the farm of Netherton of Grange, belonging to James Peterkin, eſq. by Mr. John Hoyes, his tenant; the eſtate having been let to him on a nineteen years leaſe. The work was undertaken under an agreement with the proprietor, to allow one year's rent of 195*l.* ſterling, with the further allowance of ameliorating the farm-houſes to the extent of 150*l.* more. It is ſtated in the work already mentioned, that, "under theſe circumſtances, the embankment was begun about the 1ſt of June, 1802; and, in November, it was brought to its full height over the whole; ſo that the Carſe has been completely defended from the ſea ever ſince the ſpring tides in October. He cannot poſitively aſcertain, he ſays, the extent of ground gained, as it has not been meaſured ſince the dike was erected; but, from the laſt ſurvey of that part of the eſtate, it would appear fifty acres were improveable; from which is to be deducted the quantity occupied by the baſe of the dike, the border on the outſide, with a few detached ſpots, probably included in the meaſure." The method adopted for carrying on the operations was this: "After looking over the Carſe, and marking out the line or dike, the length of which is 1400 yards, moſtly in a right line, except an angle at the diſtance of 300 yards from the weſt end, and a ſegment of a circle at about 250 from the ſouth-eaſt end, it was reſolved to make the embankment ſix feet of height in the higheſt part of the ground, and to allow two feet of breadth in the bottom of every foot of height, as ſeen by the draught of the mould at *fig.* 9. After taking the level of the Carſe, it was found, he ſays, that where the ground was low, and a good deal of it broken by runs of the ſea and outlets for the water, the dike would require to be eight and ten feet high, to have it on a level at the top; ſo that the average will be nine feet high. The embankment was built in the following manner: It was begun on the higheſt ground, near the weſt end, and two moulds ſet up at the diſtance of ſeventy or eighty yards; the height ſix feet by twelve broad in the baſe; the ſlope on the outſide ſix feet, on the inſide four feet, and the breadth at the top two feet; the ſides made up with feal from the broken ground on the outſide of the dike, which were laid with the graſs-ſide down, two feal deep on each ſide of the dike; the outſide feal of the firſt courſe with the ends out and in, and the other running along; the next courſe, the outſide feal running along, and the inſide out and in, and ſo on alternately, each courſe conſiſting of a head and runner; the body of the dike being made up of the Carſe ground from which the feal had been cut, and packed down by men with beaters. When this was brought to the height of four or five feet, another piece was begun, leaving an intermediate ſpace, where there were any water-runs, for the egreſs of the tide: this was found neceſſary, to draw off the water from the low parts of the Carſe, which would have been filled up in ſpring-tides; and, by coming in at the end and over the high ground, would have been prevented from getting out by the dike, if it had not been done in that way; ſo that the embankment was all in detached pieces, till it was brought near the height. Theſe intermediate ſpaces were then filled up, betwixt the fall of one and riſe of next ſpring-tide, after laying down wooden pipes wih ſtoppers in the dike, to carry off the ſink-water." He adds, that "it was a great labour to get the work carried on; in ſome places having to croſs over lakes and runs made by the tides, which required vaſt quantities of materials, the dike being in ſome places upwards of ten feet high, and twenty-two broad in the baſe; the greateſt part of the dike is ſixteen to eighteen feet broad. There was one lake, of 150 feet in length, and fifty feet in breadth, filled up with earth, clay, and ſand, to the height of five feet; on which the dike was then built. This forms a mound, on the outſide of the dike, of fifteen or ſixteen feet broad; and through this there are pipes laid, to carry off the ſink-water." He further adds, that "a ſtream of water formerly ran this way; but it was turned by the weſt end of the farm, by cutting a canal, which conveys the water through the embankment there, by means of an outlet built of ſtone, with a ſluice on the inſide, raiſed to the level of the running water, and a folding-door on the outſide, to be ſhut by the ſpring-tides. At this place, a road, that formerly led to Findhorn at low water through the Carſe, is carried over the top of the dike, by making a mound of earth at each ſide, with a gradual approach and deſcent." It is ſtated further, that "ſince the Carſe has been encloſed, the tides have been ſo high, that the water, during a ſevere ſtorm, was from ſix to ſeven feet deep at the back of the dike: the wind, being from the north, occaſioned a heavy ſwell and ſurge, but no water came over the top of it." He ſuggeſts, that "it is in contemplation, as ſoon as the enſuing ſeaſon permits, to cover the outſide with feals, the green ſide uppermoſt; and he has no doubt, when finiſhed, it will effectually ſecure the lands from any further viſitation of the ſea. The expences of the embankment cannot be well aſcertained at preſent; but it will be a good deal more than is allowed by the proprietors." He ſays, that "a great part of the land is already ploughed; but, the winter ſetting in ſo ſevere, prevented the whole from being done. It is intended to fallow it, in preparation for a crop of oats in the ſucceeding ſpring; but this intention may not be unalterably adhered to. There are various ſorts of ſoil in it: ſome of it clay, ſand, gravel, black rich earth, and parts of it of a moſſy nature; in ſome places below the gravel, which may, he thinks, have been forced on by the tides, a thin ſtratum of clay, upon ſand; and ſome parts, clay and ſand alternately. There are other parts not ſo rich as might be expected, the ſurface having been carried off by former tenants, for mixing in their dunghills or compoſt heaps. In *fig.* 9, *a* is the breadth of the dike at the top, when finiſhed; *b*, the breadth of dike at bottom, being twelve feet, when it is ſix feet high; *c*, the breadth when eight feet high; *d*, the breadth when ten feet high; *f*, the ſlope on the ſea-ſide of the dike, which is always equal to the half of the breadth of the bottom: the inſide ſlope, and breadth of the dike at top, is equal to the other half; and *e* is a plumb-rule in a frame, made to apply to the mould or dike: the intention of it was, to find if the dike was kept on the proper ſlope, where a line could not be applied from one mould to another, as in a round or turn, or when the moulds were obliged to be taken down; but this one only anſwered for the ſea-ſide, another being uſed for the inſide, to fit its ſlope." *Fig.* 10. is a ſcale of the mould one-eighth of an inch to a foot.

Various other improvements of this nature have been accompliſhed, in particular circumſtances and ſituations; and large tracts of land thereby rendered more than doubly beneficial to their occupiers. The methods which have been had recourſe to, in ſuch caſes, will be fully detailed in ſpeaking of *Hough-land* and *Rivers*.

A curious, uſeful, and highly ingenious method of embanking, and preventing the waters of the tides from ſoaking through the porous banks, formed in fenny and mooriſh ſituations, has been deſcribed by Mr. John Smith, in the fourth volume of "Communications to the Board of Agriculture," who begins by "conciſely obſerving, that the great land of the fens is divided into three large levels; and that each of theſe levels is ſubdivided into numerous diſtricts by banks: but as theſe banks are made of fen moor, and other light materials, whenever the rivers are ſwelled with water, or any one diſtrict is deluged either by rain, a breach of banks, or any other cauſe, the waters ſpeedily paſs through theſe light, moory, porous banks, and drown all the circumjacent diſtricts. The fens have ſometimes ſuſtained 20,000*l.* or 30,000*l.* damage by a breach of the banks; but theſe accidents ſeldom happen in the ſame diſtrict twice in twenty years; the water, however, ſoaks through all fen-banks every year, in every diſtrict; and when the water-mills have lifted the waters up out of the fens into the rivers in a windy day, a great part of the water ſoaks back through the porous banks, in the night, upon the ſame land again." And he adds, that "this water that ſoaks through the bank drowns the wheat in the winter, waſhes the manure into the dikes, deſtroys the beſt natural and artificial graſſes, and prevents the fens from being ſown till too late in the ſeaſon. This ſtagnant water lying on the ſurface, cauſes alſo fen agues, &c. Thus, ſays he, the waters that have ſoaked through the porous fen-banks have done the fertile fens more real injury than all the other floods that have ever come upon them."

Having been much concerned in fen-banking from his youth, he had ſome time ſince deviſed the plan which he now finds to anſwer ſo well; but found it difficult to prevail with any gentleman, who had a proper extent of this ſort of land, to give it a fair trial. However, during the laſt autumn, he prevailed with a perſon in the pariſh where he lives to try it, which ſhewed it to be equal to his higheſt expectations.

This improved method of embanking chiefly conſiſts in this: that "a gutter is cut eighteen inches wide, through the old bank down to the clay, (the fen ſub-ſtratum being generally clay,) the gutter is made near the centre, but a little on the land-ſide of the centre of the old bank. This gutter is afterwards filled up in a very ſolid manner with tempered clay; and to make the clay reſiſt the water, a man in boots always treads the clay as the gutter is filled up. As the fen-moor lies on clay, the whole expence of this cheap, improved, and durable mode of water-proof banking coſts in the fens only ſixpence *per* yard. This plan was tried laſt autumn on a convenient farm, and a hundred acres of wheat were ſown on the land. The wheat and graſs lands on this farm are now all dry, whilſt the fens around are covered with water. This practice anſwers ſo well on this farm, that all the farmers in this pariſh are, he ſays, improving their banks in the ſame manner, and ſome have begun in adjacent pariſhes."

It is unqueſtionably a mode of practice that requires to be fully known and underſtood, in all thoſe diſtricts which have lands of this deſcription; as by it great advantages may probably be derived.

Embanking againſt Lakes.—The buſineſs of forming embankments, in caſes of what are termed lakes, or mires, in this part of the country, and loughs in Scotland and Ireland, is much more ſimple and eaſy than in the preceding caſes. It has been remarked by Mr. Beatſon, that the waters in theſe ſituations generally ſubſide during the ſummer months, riſing conſiderably in winter, and whenever the ſeaſon is very wet. In particular caſes, the extent of ſurface, which is overflown in the winter ſeaſon, ſo far exceeds that which it covers during the ſummer, that it would be an object, and ſometimes a conſiderable acquiſition, to confine the water within its ſummer boundaries, or to cut off ſome of its parts. Where theſe are intended, the principal outlet muſt be firſt carefully examined, and be conſiderably widened and enlarged; which, on the principle already noticed, in ſpeaking of rivers, will prevent the water from riſing ſo high as was formerly the caſe. Where the levels will not admit of much depth being had, or where the ground is of a rocky nature, and would of courſe be difficult and expenſive to deepen, the breadth ſhould be increaſed as much as poſſible, and all obſtacles cleared away, that the water may run freely in a ſhallow ſtream. Where it is required to aſcertain with exactneſs, or to fix with certainty, the future limits of the water, a ſection of the greateſt quantity running out during a flood ſhould be taken. Suppoſe this ſection, for example, be ten feet in width and four feet in depth; by making it forty feet in width, the ſame quantity of water will not riſe above one foot: conſequently, by this means alone, three feet in height will be gained all round the lake, which, in caſe of embanking it, would be a great object. During the ſummer ſeaſon, when the water is loweſt, is the moſt proper time for carrying on theſe, as well as other embankments. When, however, any materials are to be brought from a diſtance, they may be laid down or be prepared at other ſeaſons, with the exception of turf, which ſhould always be uſed as ſoon as poſſible after it is cut. The manner of conſtructing embankments of this kind may be ſufficiently underſtood, from what has been already ſaid in the other deſcriptions of embankments: obſerving, however, as a general rule, that when the materials on the ſpot will anſwer the purpoſe, they ſhould invariably be made uſe of, although at the expence of digging a trench larger and deeper than would otherwiſe be neceſſary. It ſhould conſtantly be attended to, in executing all ſorts of embankments, that the greateſt care be taken to make them perfectly firm and ſolid, by continually beating them, and examining them carefully, during the whole of the time they are in the ſtate of being formed.

The various methods and plans of management, which are neceſſary to be adopted in the improvement of ſuch lands as have been gained from the ſea, will hereafter be more fully conſidered and explained. See Marsh-*Land.*

Embankment, in *Canal-making*, is a term for any large mound of earth, either for confining the water of a canal or reſervoir, or upon which a canal or aqueduct is formed acroſs a valley or low piece of ground. It may have arches under it, for the paſſage of a road, a river, or brook: ſuch are called *aqueduct-arches*, and ought by all means to be conſtructed on the true curve of equilibration, for avoiding the great expence and diſgrace which attends the failure of leſs ſcientific arches, as at Wolverton on the Grand Junction Canal. See Canal.

EMBAR, in *Geography*, a town of Africa, in the country of Senegal.

EMBARCADERO, in *Commerce*, a Spaniſh term, much uſed along the coaſts of America, particularly thoſe on the ſide of the South ſea.

It ſignifies a place which ſerves ſome other conſiderable city farther within land, for a port, or place of ſhipping, *i. e.* of embarking and diſembarking commodities. Thus Calao is the embarcadero of Lima, the capital of Peru; and Arica the embarcadero of Potoſi. There are ſome embarcaderos forty, fifty, and even ſixty leagues off the city which they ſerve in that capacity.

EMBARGO, a reſtraint or prohibition, laid by a ſovereign on merchant-veſſels, to prevent their going out of port; ſometimes to prevent their coming in; and ſometimes both, for a limited time. See Proclamation.

Embargoes are uſually in time of war; in apprehenſions of invaſions, &c. One great occaſion of embargoes is, that the government may make uſe of the merchant-veſſels, with their equipage, &c. in armaments, expeditions, tranſporting of ſoldiers, &c.; another is, to ſtop the communication of intelligence at ſuch critical ſeaſons. Embargoes are of very miſchievous conſequence to commerce.

EMBARKATION *of Ordnance and Stores.* The firſt thing neceſſary is to prepare a liſt of all the articles to be embarked, with the weight of each. This liſt muſt have an ample column for remarks; and the reputed tonnage muſt have an allowance of one-third added, for all articles whoſe weights and meaſures are not alwaye the ſame, but receive, or loſe, in conſequence of damp, dirt, &c.; ſuch as tents, &c.: but the tonnage of ordnance, ſhells, ſhot, &c. ſhould be ſet down at their actual weight, according to their natures, calibres, &c. reſpectively. If veſſels are paid for according to the tonnage they carry, the maſter will, of courſe, ſtow away to the beſt advantage, and load with as much as the veſſel can poſſibly contain; whereas when freighted for a voyage, upon the eſtimated tonnage of the hold, they will ſtow ſo very looſely, as both to carry leſs, and to ſubject the cargo to conſiderable injury. It is, therefore, proper that a naval officer ſhould be appointed to ſuperintend every embarkation, and to ſee that every thing is ſtowed to the beſt advantage. It may be uſeful, in this place, to ſhew how tonnage is eſtimated. The uſual method of finding the tonnage of any ſhip is,—Multiply the length of the keel by the length of the beam, and half that product by the breadth of the beam; divide the laſt product by 94, and the quotient will be the ſhip's tonnage. Thus, ſay a ſhip's keel meaſures 90 feet, and that her beam, *i. e.* her extreme breadth, be 30:

$$90 \times 30 = 2700 \times 15 = \frac{40500}{94} = \overset{\text{Tons.}}{430.8}$$

The tonnage of goods and ſtores is taken ſometimes by weight, and ſometimes by meaſurement; and that method is allowed to the veſſel which yields the moſt tonnage: were it otherwiſe, the owners would be conſiderably loſers in the freight of bulky, light articles, on which the calculation by weight would give them but little claim to charge; and, *vice verſâ*, if ordnance, ſhot, &c. were to be carried by meaſurement, they would be under a ſimilar diſadvantage. In tonnage by weight, 20 cwt. make a ton; and in tonnage by meaſurement, 40 cubic feet make a ton, the ſame as in timber computations. All carriages, or other ſtores to be meaſured for tonnage, ſhould be reduced to their ſmalleſt dimenſions, by taking to pieces, and packing into as little ſpace as poſſible. All ordnance is ſhipped according to actual weight; as are alſo muſket cartridges in boxes or barrels, and other ſuch ponderous articles. The following table will exhibit the rates of tonnage allowed for the embarkation of the moſt material ſtores in the ordnance department.

EMBARKATION.

Do. 2 Buſhels	250	0	8	1

When ordnance and ſtores are embarked, all appertaining to the ſame ſpecies ſhould be claſſed and divided into the ſeveral veſſels, in ſuch manner as may inſure the ſafe arrival of a certain portion; thereby avoiding that great inconvenience which could not fail to ariſe, were any one veſſel, containing the whole of any particular ſtores, to be loſt, taken, or unable to make the place of deſtination. With each piece of ordnance ſhould be embarked every thing neceſſary for its ſervice; ſo as to be inſtantly come at, when required to be landed. This principle ſhould be carried to the fulleſt extent: even the platforms for the battering cannon ſhould be in the ſame veſſel with them; and, in ſhort, every precaution ought to be taken to obviate delay, or omiſſion, or imperfection. In general, all the heavy ſtores ſhould be put in firſt; both to prevent their cruſhing leſs ſubſtantial articles, and to ſerve as ballaſt: the lighter ſtores, being generally moſt periſhable, ſhould be ſtowed uppermoſt, and be all numbered according to their ſeveral natures, and to their ſeveral intentions. Thus, every piece of ordnance, its carriage, and even all the parts of that carriage, together with its ſponges, rammers, limbers, and boxes, ought to bear the ſame number; ſo that, when about to be landed, the whole may be diſcharged at one time from the ſhip, and be ſent on ſhore in that regular manner, which may enable the artillery men and artificers to mount every one in ſucceſſion with promptneſs and exactitude. All the cheſts, barrels, &c. muſt be lettered and numbered diſtinctly, in ſuch manner as may indicate their reſpective contents. The numbers, &c. ought to be painted in clear white on a black ground, thereby to be legible at night: for the ſame purpoſe, it would perhaps be found uſeful to have the letters marked with white-headed tacks; ſo that, when not legible, for want of light, as often happens, they may be traced with the finger. In ſhipping gun-carriages, it is eligible to ſend them down into the hold, &c. without taking off the axle-trees from the cheeks; as they cannot be replaced without proper workmen, and a tedious operation. When a carriage is diſmounted, all the ſmall articles, ſuch as elevating-ſcrews, linch-pins, drag-waſhers, &c. ſhould be carefully collected, and ſecured either in a ſmall box, or in a bag of leather, tarpaulin, &c. duly marked.

In order to give more room, all articles, of the ſame deſcription in particular, ſhould be placed ſo as to lock into each other, or to fit in ſuch manner as may leave the leaſt poſſible intervals. A perſon ſhould attend to regiſter, not only the ſeveral articles as they ſhould be ſhipped, but to note the exact part of the hold, &c. where each might be ſtowed. Theſe precautions, added to the affixment of particular marks, ſuch as numbers, in white paint, on each bow, and each quarter of every tranſport, ſo as to be diſtinguiſhable at ſeveral miles diſtance, will tend conſiderably to facilitate the debarkations, and enable the ſeveral commanders and public officers to aſcertain with perfect preciſion the amounts of loſſes, and the ſituations of the ſeveral ſtores, according as veſſels may lie to windward, or to leeward, &c. It is a matter of conſiderable importance in embarking ſtores, to have them ready at hand which would be the firſt wanted in caſe of emergency: as well as to arrange them in ſuch manner as ſhould anſwer the purpoſes of the expedition in the moſt efficacious manner. Thus, if it is expected that troops will have to diſembark in the preſence of an enemy, the light field-pieces, and howitzers, in lieu of being ſent below, ought to be kept, together with all their implements, and a certain portion of their ammunition in ſome ſecure part, whence they could be lowered into the boats at a ſhort notice. Entrenching tools ſhould alſo be held in equal readineſs, together with abundance of ſand-bags. When troops are to be embarked, every precaution muſt be taken to prevent confuſion, and to obviate danger. Certain corps ſhould be appointed to be in readineſs on given days at particular ports; taking with them only ſuch baggage as ſhould be allowed on the occaſion. The ſtores of every deſcription and the diſpoſable lumber ſhould be previouſly ſent on board, under charge of the quarter-maſter, who ſhould be particular in ſeeing that every thing neceſſary to the comfort and efficiency of the troops were duly arranged. The tranſports being in readineſs, they ſhould, if poſſible, be brought up to a pier, ſo that, by the aid of gang-boards, the files might march on board at once; otherwiſe recourſe muſt be had to boats and ſmall craft, in which the troops muſt proceed from the ſhore to the ſhipping. The lee-ſide is generally preferred for embarking; it being the ſmootheſt water, and often the aſcent up the gang-ladder leſs difficult. The ſafeſt mode is for the arms to be handed up into the main chains, and from thence into the veſſel. The bayonets ought to be well ſecured to their ſcabbards, and the pouches ſhould be buttoned down. The men neareſt the gang-ladder ſhould be the firſt to aſcend; the others taking care to balance the boat, &c. as ſhe becomes lighter, and requiring equipoiſe in conſequence of being quitted by the troops. It ſhould be obſerved as a ſtanding regulation never to let one boat lie abreaſt of another that is diſcharging her crew into a veſſel: otherwiſe there will not only be danger of broken-legs, but of being upſet: each boat ſhould range up under the lee-quarter, in ſucceſſion, and when evacuated by the troops ſhould pull a-head, by means of a painter, or a boat-hook, ſo as not to impede its ſucceſſor. When the troops are on board boats, they ſhould ſit as low as poſſible, keeping their muſkets perpendicular, and reſted on the bottom, or on their own feet. In going on board the men ſhould proceed very leiſurely and ſilently to their places, ſpreading ſo as to preſerve the due time of the boat, and ſitting down ſo ſoon as duly arranged. In caſe of accident, or running foul of any other veſſel, they ſhould be particularly enjoined to remain ſeated, and not to obſtruct the boat's crew in their endeavours to remedy the miſhap. Where troops are to embark in the face of an enemy, the greateſt order and coolneſs will be requiſite; eſpecially when within the reach of their cannon. If the embarkation in boats is to be made from a ſhip, they muſt all be manned from that ſide leaſt expoſed to the enemy's fire; the ſhip covering them as they ſucceſſively put off, and reſt on their oars, until the whole may be ready to ſtart together by ſignal; after which no time ſhould be loſt in gaining the ſhore, and in forming on the beach. It ſometimes occurs, that a river is to be croſſed in boats for the attack of an enemy poſted on the oppoſite bank: in ſuch caſe, the number of boats being previouſly aſcertained, the troops muſt be told off into as many diviſions as there may be veſſels to convey them, the ſtrength of each diviſion correſponding with the tonnage of that it is to occupy. Each diviſion then proceeds on board with rapidity, but with perfect regularity, and the whole put off without delay. Where the water is rather ſhallow, the boats muſt lie out ſo far as to be afloat after the men have, by wading, got on board. All debarkations from boats and ſhipping ſhould be conducted with as much order as circumſtances may admit; and even when troops are driven back to their boats, as much ſhould be preſerved as the preſſure of purſuit may allow. It is a well-known fact, that many re-embarkations have taken place in the preſence of a ſuperior force without diſorders, or allowing the enemy to make a ſingle priſoner. The greateſt danger generally ariſes from allowing the boats to lie in ſo cloſe, as to touch the ground, whereby, when the troops have got on board, they have been unable to puſh off, and thus remained ſubject to a galling fire. When re-embarking after a repulſe, it ſhould be ſtudied to man ſome of the craft, (eſpecially a few of the lighteſt conſtruction, and any gun-boats whoſe draught of water may allow them to lie near the beach,) for the purpoſe of covering the retreat, and to take in flank ſuch of the enemy as ſhould follow the fugitives into the water. When ſuch a precaution is obſerved, the embarkation will proceed quickly, and the enemy will content themſelves with a diſtant fire on the retreating force; in lieu of mixing pell-mell, as they would do if there exiſted no pre-eſtabliſhed check. Troops embarked on board tranſports, or ſhips of war, are only allowed three-fourths of a ſeamen's ration of proviſions; unleſs when acting as marines, when they are on a footing. The meſſes are formed of ſix men in each, for each of which a ſpace of ſix feet ſquare is allowed, that is, 36 ſquare feet; but only four are ever there at the ſame time, it being a rule that one-third of each meſs ſhould always remain on deck. When embarked for foreign ſervice, ſix women are allowed proviſions for every hundred men; and when on home ſervice, ten women are allowed with the ſame number. That part of the charter-party which relates to the proviſion, firing, candles, utenſils, &c. intended for the uſe of the troops, is always ſubject to the inſpection of their commanding officer on board; and is ſometimes copied out, and hung up in the cabin, open to the peruſal of all. The regulations regarding ſmoking, extinction of lights, &c. are alſo poſted up in various parts, together with the whole allotment in regard to births, meſſes, and particularly the accommodations for the officers of the veſſel, and thoſe attached to the troops. It being neceſſary to eſtabliſh ſome limit for the quantities of baggage taken on board, the following proportions were fixed for that purpoſe.

For a field-officer - - -	five tons.
For a captain - -	three tons.
For a ſubaltern - -	a ton and a half.

General officers are rarely limited, but it is uſually intimated to all embarking, that the quantity of baggage ſhould be reduced as much within bounds as might be practicable.

The embarkation of horſes is uſually effected by means of ſlings of canvas, which paſſing under their bellies, and being duly ſecured with cords, enable the crew to hoiſt them in, and to lower them down between decks without doing the ſmalleſt injury to the animals; which, however ſpirited they may be while on terra firma, generally become perfectly paſſive under ſuch circumſtances. On arriving at the place of deſtination they are debarked in the ſame manner. It certainly is among the moſt important improvements in this branch of ſervice, that the horſes can be ſlung, during bad weather, to the beams in ſuch manner as to prevent their ſuffering in conſequence of the ſhip's motion. Yet we cannot but judge, from the crippled ſtate in which cavalry are ſometimes debarked, that much room remains for improvement.

EMBARRAS, EMBARRASMENT, a French term, though now naturalized; denoting a difficulty, or obſtacle, which perplexes or confounds a perſon, &c.

EMBASIS, in the writings of the *Ancient Phyſicians*, the name of a large veſſel, in which they prepared their medicated baths, and which was capable of holding the perſon to be bathed at his full length.

EMBASSADOR, or AMBASSADOR, is a public miniſter ſent from one ſovereign prince or independent ſtate to another, as a repreſentative of that prince or ſtate, and furniſhed with credentials which verify his miſſion as an embaſſador.

Such a public miniſter is called in Latin *legatus*, or *orator*, but the meaning of the word embaſſador is much more extenſive. The only circumſtance in which the modern embaſſador and the ancient legatus agree is the protection of the law of nations. See LEGATION.

The Engliſh word embaſſador is probably derived from the Spaniſh *embaxador*, the ſame as the French *ambaſſadeur*, which comes from *ambaſciator*, a Latin word of the middle age, formed of *ambactus*, or *ambact*, an agent, domeſtic, or client among the Gauls. The term *ambaſcia* is found in the Salic law, Tit. xix. and in the law of Burgundy.

The cuſtom of ſending embaſſadors dates from the origin of civil ſocieties. As ſoon as mankind were divided into diſtinct nations, differences would ariſe which muſt be amicably ſettled by the interference of neighbours, guarded againſt by the protection of the more powerful, or decided by wars ending in reconciliations. The negociating of theſe mediations, alliances and treaties of peace is entruſted to public miniſters; and ſovereign princes having, like private perſons, intereſts to diſcuſs with other princes regarding their own concerns as individuals, ſuch as the contracting of matrimonial alliances; the management of theſe tranſactions is likewiſe confided to public miniſters, or negociators. See NEGOCIATION.

Among the public miniſters ſent as negociators, from one independent ſtate or ſovereign prince to another, embaſſadors hold the firſt rank. Envoys, miniſters plenipotentiary, and reſidents, are negociators of leſs eminence. (See ENVOY, PLENIPOTENTIARY, and RESIDENT.) Their functions are the ſame; they are equally under the protection of the law of nations, and they enjoy nearly the ſame privileges.

The pre-eminence of embaſſadors manifeſts itſelf chiefly in the particular ceremonial of their reception in the country where they are appointed to reſide. They are entitled to be ſaluted with the firing of guns; to be complimented by deputies of the prince or ſtate to which they are ſent; to make a ſolemn public entry; to ſpeak at the audiences they obtain with their heads covered; to have places of honour aſſigned to them at all public ceremonies; to keep a canopy or throne in their dwelling; and, ſince the year 1593, when this title was firſt given them at Rome, to be ſtyled excellencies. The name of embaſſador, Cicero obſerves, is ſacred and inviolable: "non modo inter ſociorum jura, ſed etiam inter hoſtium tela incoluma verſatur:" (In Verr. orat. 6.)

The privileges which embaſſadors ſhare with other public miniſters, ſent as negociators, are.

1. The right of being received by the prince or ſtate to which they are deputed, unleſs there be a juſt cauſe for refuſing to receive them. The duke of Buckingham, ſays Hume, had Engliſh familiarity, and French levity, two of the moſt offenſive qualities in an embaſſador. When, in 1626, he was deſirous of being once more embaſſador at the French court, it was ſignified by the French embaſſador to the court of St. James's that for reaſons well known to the duke his perſon would not be agreeable to his moſt Chriſtian majeſty. His preſumption to talk of love to the queen in a former embaſſy had given offence, and would have been a juſt cauſe for his non-admiſſion.

The correſponding obligation of receiving foreign embaſſadors has its foundation in the deareſt intereſts of ſociety and of humanity. As nations are in continual need of mutual aſſiſtance, they could never freely communicate, if the law of nations had not made it an imperious duty to all ſtates to admit the embaſſadors who are ſent to them. Even the embaſſadors of an enemy have a right to be received and to be heard, ſince it is the duty of nations at war with each other to endeavour by all poſſible means to re-eſtabliſh the accuſtomed relations of peace and amity.

2. The inviolability of their perſons. Embaſſadors repreſent the ſovereign or chief magiſtrate of an independent ſtate; their miſſions are frequently of the moſt delicate nature, and could not be accompliſhed if the ſecurity of their perſons were not expreſsly provided for. Thoſe who inſult an embaſſador infringe not only the civil law, which forbids the doing of injuries in general, but more particularly the public law of nations, which extends its ſpecial protection to public miniſters, that the harmony of nations may not be diſturbed, or if unfortunately the ties of friendſhip have been broken, that the effecting of a reconciliation may labour under no reſtraint. The ſmalleſt inſult offered to an embaſſador ought to be puniſhed with the greateſt ſeverity; the neglect to puniſh the offender is a juſt cauſe of war.

If an embaſſador groſsly offends, or makes an ill uſe of his character, he may be ſent home, and accuſed before his maſter: who is bound either to do juſtice upon him, or avow himſelf the accomplice of his crimes. (Mont. Sp. of L. 26. 22.) But writers on the law of nations are not agreed, whether this exemption of embaſſadors extends to all crimes, as well natural as poſitive: or whether it only extends to ſuch as are *mala prohibita*, as coining, and not to thoſe that are *mala in ſe*, as murder. Our law ſeems formerly to have taken in the reſtriction, as well as the general exemption. For it has been held, both by our common lawyers and civilians (1 Roll. Rep. 175. 3 Bulſtr. 27.) that an embaſſador is privileged by the law of nature and nations; and yet if he commits any offence againſt the law of reaſon and nature, he ſhall loſe his privilege (4 Inſt. 153.); and therefore, if an embaſſador conſpires the death of the king in whoſe land he is, he may be condemned and executed for treaſon; but if he commits any other ſpecies of treaſon, it is otherwiſe, and he muſt be ſent to his own kingdom. However, the general practice of this country, as well as of the reſt of Europe, ſeems now to purſue the ſentiments of the learned Grotius, that the ſecurity of embaſſadors is of more importance than the puniſhment of a particular crime. And therefore few, if any, examples have occurred within a century paſt, where an embaſſador has been puniſhed for any offence, however atrocious in its nature.

Even the domeſtics and the perſons in the retinue of an embaſſador are inviolable. If any one of them were inſulted, the puniſhment ought to be as ſevere as if the inſult had been offered to the embaſſador himſelf. The domeſtics of the duke of Créqui, French embaſſador at Rome, having been inſulted by the Corſican guards of Pope Alexander VII. Louis XIV. inſiſted upon their being ſeverely puniſhed.

But this inviolability extends only to the perſons who compoſe the embaſſador's family, as his wife and children, and who being actually in his retinue are regiſtered as ſuch by the police of the country where he reſides. Should, however, any of them be guilty of a great crime, as a forgery, theft, or murder, it would be no violation of the law of nations to claim the offender, and to puniſh him according to the laws of the country. When Sully reſided in England as embaſſador of Henry IV of France, he was informed that one of his gentlemen had killed an Engliſhman in a houſe of ill fame. He immediately got him arreſted, and ſent word to the magiſtrates of London that they might ſeize the murderer. The latter having been tried, the king of England granted him his pardon and his liberty.

In conſequence of this inviolability the actions of an embaſſador or of any perſon in his retinue are not ſubject to the controul of the private law of the country in which he is appointed to reſide; and with regard to civil ſuits they cannot be proſecuted for any debt contracted in that country as long as the embaſſador continues in it in his public capacity. This privilege is allowed in the Engliſh courts of law, and, the more effectually to enforce the law of nations in this reſpect, when violated through wantonneſs or inſolence, it is declared by the ſtatute 7 Ann. c. 12. (an act paſſed in 1708, in conſequence of the arreſt of an embaſſador from Peter the Great, czar of Muſcovy, for a debt of 50*l*.) that all proceſs whereby the perſon of any embaſſador, or of his domeſtic or domeſtic ſervant, may be arreſted, or his goods diſtrained or ſeized, ſhall be utterly null and void; and that all perſons proſecuting, ſoliciting, or executing ſuch proceſs, being convicted by confeſſion on the oath of one witneſs, before the lord chancellor and the chief juſtices, or any two of them, ſhall be deemed violators of the laws of nations, and diſturbers of the public repoſe; and ſhall ſuffer ſuch penalties and corporal puniſhment as the ſaid judges, or any two of them, ſhall think fit. But it is expreſsly provided, that no trader, within the deſcription of the bankrupt laws, who ſhall be in the ſervice of any embaſſador, ſhall be privileged or protected by this act; nor ſhall any one be puniſhed for arreſting an embaſſador's ſervant, unleſs his name be regiſtered with the ſecretary of ſtate, and by him tranſmitted to the ſheriffs of London and Middleſex. Theſe exceptions are ſtrictly conformable to the rights of embaſſadors, as obſerved in the moſt civilized countries. In conſequence of this ſtatute, thus declaring and enforcing the law of nations, theſe privileges are now held to be part of the law of the land, and are conſtantly allowed in the courts of common law. (Fitz. 200. Stra. 797.) Blackſtone's Commentaries, vol. i. and iv.

3. The moſt perfect freedom and independence in the diſcharge of their official duties. This is a further conſequence of their inviolability. If an embaſſador ſhould even excite diſturbances, or enter into any conſpiracy againſt the prince, or the ſtate to which he is ſent, the general practice of Europe is in favour of the opinion of the learned Grotius, in his book "De Jure Belli et Pacis," that the inviolability of an embaſſador is of greater importance than the puniſhment of a particular crime. His public character ought to be conſtantly and invariably reſpected; but he may be diſmiſſed, and ſent back to the prince or ſtate whoſe repreſentative he is. The biſhop of Roſs, embaſſador of the queen of Scotland at the court of Weſtminſter, having engaged in a conſpiracy with the duke of Norfolk againſt the queen, he was arreſted, confronted with his accomplices, and ſent back to Scotland. In the reign of Henry IV. of France, the Spaniſh embaſſador took a part in the conſpiracy of the count d'Auvergne and duke d'Angoulême, who were both tried; but no mention was made of the embaſſador. A certain Mérargues had agreed, with the ſecretary of the ſame embaſſador, to deliver Marſeilles into the hands of the Spaniſh monarch. The French parliament condemned Mérargues to death; but the Spaniſh ſecretary was delivered to the king of France, who gave him up to the Spaniſh embaſſador, and obliged the latter to ſend the ſecretary out of the kingdom.

If an embaſſador be diſmiſſed and eſcorted to the frontiers, he is entitled to the privileges and immunities of his dignity, as long as he is on the territory of the ſtate that ſends him back. He ought alſo to be allowed a convenient time to prepare for his departure. This indulgence muſt even be granted to the embaſſador of a power againſt which a declaration of war has been iſſued, and he muſt be furniſhed with paſſports to return home unmoleſted. The cuſtom of the Turks, who, in the caſe of war being declared, confine the embaſſador of the power againſt which it is declared in the caſtle of the Seven Towers, is in direct violation of the law of nature, and of the public law of nations. The enlightened ſovereigns of Europe ſhould join in remonſtrating againſt ſo unjuſt a practice, and inſiſt upon its abolition.

4. The inviolability of the houſe in which they reſide. An embaſſador's dwelling is a ſacred aſylum, where no perſon can be arreſted without the embaſſador's conſent. Any felon, however, that might have taken refuge in an embaſſador's houſe, ought to be given up to the criminal juſtice of the country.

Neither have embaſſadors the right of trying or puniſhing, within the walls of their manſion, perſons of their retinue who have been guilty of any crime. Though independent of the criminal and civil laws of the country in which they reſide, they cannot exerciſe any judicial functions, becauſe the judicial power of the ſovereign they repreſent does not extend to that country.

5. The right of having divine ſervice performed in their houſes, at a chapel of their own, according to the rites of the worſhip of their country: but embaſſadors cannot claim the free acceſs of others to their chapel than the ſubjects of the country they repreſent, who are under their ſpecial protection in this reſpect. At the time when the Proteſtants were cruelly oppreſſed and perſecuted in France, the French Proteſtants reſiding at Paris have frequently been moleſted in going to and coming from the chapel of the Dutch embaſſador; but he had no right to remonſtrate againſt this cruelty, becauſe it was exerciſed on the ſubjects of the king of France.

6. The right of being exempt of all duties, charges, taxes, impoſts, exciſe and cuſtom dues. This right has ſometimes been reſtricted in countries where it had been abuſed by embaſſadors, who, forgetful of their dignity, had not ſcrupled to make it a cover to an illicit trade.

7. The privilege, that in caſe of death, the houſehold furniture, moveables, and perſonal property of embaſſadors, or of any individual in their retinue, devolve to their heirs, though aliens, without being liable to any deduction, tax, or alien duty, commonly called "Droit d'Aubaine." But this right does not extend to immoveables, or landed property.

8. The right of legalizing or certifying the authenticity of documents or writings which are to be tranſmitted to the ſtate or country which they repreſent, and that of granting paſſports to the natives of that country.

9. The right of following the court at which they are appointed to reſide, to whatever place that court is removed to, unleſs the prince ſhould declare his abſence to be merely temporary, and requeſt the embaſſador's non-attendance. During the ſeven years' war in Germany, from 1756 to 1763, the Engliſh embaſſador at the court of Berlin attended the great Frederick of Pruſſia at all his head-quarters.

10. Laſtly, embaſſadors conſider themſelves as entitled, and indeed cuſtom appears to have ſanctioned it as a right, to receive ſome valuable trinkets as preſents at their laſt audience, when they take leave of the prince at whoſe court they have reſided.

Embaſſadors ought to be very attentive not to ſuffer any of their privileges or immunities to be infringed upon; neither ought they to paſs over any attack on the perſon or dignity of the prince, or on the character of the ſtate they repreſent. Whenever they have a complaint of a breach of privilege to prefer at the court where they are appointed to reſide, they are ſupported in their demands of redreſs by the whole diplomatic body, or corps diplomatique, that is to ſay, by the aggregate of all the foreign miniſters reſiding at the ſame court.

But embaſſadors cannot claim their privileges and immunities, unleſs they have proved their miſſion as embaſſadors by the delivery of their credentials; nor can they diſplay their character of public miniſters in any other country than that to which they are ſent in that quality. When they are under the neceſſity of traverſing the dominions of any other ſovereign prince, they muſt provide themſelves with the permiſſion to travel through that country by means of regular paſſports, for the law of nations does not oblige a prince or nation to reſpect an ambaſſador on his journey through their country, if he ſhould attempt to traverſe that country without having previouſly obtained their permiſſion.

At Athens the embaſſadors from foreign princes and ſtates always mounted the tribunal, or pulpit, of the public orators, and there opened their commiſſion, and acquainted the people with their buſineſs. At Rome they were introduced to the ſenate, and delivered their commiſſion to them. Among us they make their addreſs immediately and ſolely to the king.

Athens and Sparta, ſays M. Tourreil, when in all their glory, were never ſo much delighted as to ſee and hear a number of embaſſadors in their aſſemblies, ſuing for their protection or alliance. It ſeemed to them the nobleſt homage that could be paid them; and that ſtate which received the moſt embaſſies, was judged to have the advantage over the other.

There are ſome uſages to which embaſſadors ought to conform. They ſhould never attend at any marriage, chriſtening, funerals, or other private ſolemnity; nor muſt they even go into mourning on any occaſions of their own, becauſe they are no longer private individuals; they are the repreſentatives of a ſovereign prince or independent ſtate.

Embaſſadors, in modern times, are either *ordinary* or *extraordinary*.

An *embaſſador ordinary* is he who conſtantly reſides at the court of a ſovereign prince or independent ſtate, to maintain a mutual good underſtanding between the two ſtates, to watch over the permanent intereſts of his country, to tranſact ſuch affairs as may occur, and to give a regular account of his proceedings and obſervations to the prince or ſtate which he repreſents. The practice of keeping embaſſadors ordinary in foreign courts is but of modern invention. It is generally aſcribed to the cardinal de Richelieu. Raymond de Beccaria, baron de Forquevaux de Pavie, knight of the order of St. Michael, was one of the firſt public miniſters who reſided permanently at a foreign court. He was ſent to Spain in 1565, as embaſſador ordinary of Charles IX. of France at the court of Philip II. probably on account of the miſunderſtanding which prevailed between the Spaniſh monarch and his conſort Elizabeth, who was a French princeſs.

The frequent intercourſe which takes place between modern nations; the many relations in which they ſtand to each other; their mutual intereſts; their political and commercial jealouſies; the wiſh of being rapidly and confidently informed of their reſpective projects, enterpriſes, connections and partialities, of the ſprings by which their governments are ſet in motion, and of the general adminiſtration of their concerns abroad and at home; and laſtly, the want of a powerful protection for individuals trading in foreign countries, are indeed circumſtances which confer on the permanent reſidence of public miniſters in foreign courts a high degree of public convenience and utility. Every independent European ſtate has adopted the practice, except the Helvetian Republic, and the ſublime Ottoman Porte. Theſe two ſtates have hitherto at leaſt employed only embaſſadors extraordinary.

An *embaſſador extraordinary* is he who is ſent from one ſovereign prince or independent ſtate to another on ſome particular occaſion or emergency, and who retires as ſoon as the buſineſs of his miſſion is terminated. Hence it follows that an embaſſador extraordinary may be diſpatched to a court or country where an embaſſador ordinary of the ſame prince or ſtate is permanently reſiding. Thus the king of Great Britain appointed Mr. Roſe embaſſador extraordinary to the United States of America in 1808, for one particular purpoſe, whilſt the honourable Mr. Erſkine continued as Britiſh embaſſador ordinary at Waſhington.

In ancient times, all embaſſies were extraordinary. They were generally undertaken from motives of neceſſity, policy, or adulation, ſometimes even from the mere love of magnificence, and commonly compoſed of a great number of embaſſadors. This uſed alſo to be the caſe with the extraordinary embaſſies of the Swiſs, becauſe every canton appointed its embaſſadors. The embaſſy which Switzerland ſent to the king of France in 1663, conſiſted of forty-two embaſſadors.

In our days, extraordinary embaſſies of more than one embaſſador, are very rare; at leaſt they never conſiſt of more than three embaſſadors. Their number, however, is noways limited by the public law of Europe; neither is the retinue or train of an embaſſador extraordinary reſtricted to any particular number of perſons. It ought only not to be ſo numerous as to create any uneaſineſs in the country where the embaſſador extraordinary is appointed to ſojourn for a ſhort time. The duke of Feria, who went to France as embaſſador extraordinary of the king of Spain, to compliment Louis XIII. on his acceſſion to the throne, after the death of Henry IV. had ſo numerous a retinue, that the governor of Bordeaux refuſed to admit him in that city. He aſſigned him his quarters in one of the ſuburbs, and wrote to inform him, that he could not admit him in the place, becauſe his train formed a ſmall army, which might eaſily aſſail the governor with a thouſand firelocks. This cautious conduct of the governor was fully approved of at the French court.

Extraordinary embaſſies are generally very brilliant. The earl of Mancheſter's public entries into Venice as extraordinary Engliſh embaſſador in 1698 and 170 , are deſcribed as uncommonly magnificent. His excellency was attended by ſixteen footmen, and ſix pages, dreſſed in velvet and gold brocade, beſides his ſecretary, and a conſiderable number of Engliſh gentlemen.

The embaſſador extraordinary has the precedency before the embaſſador ordinary of the ſame power. When it happens that an embaſſador extraordinary is ſent to the ſame court after another embaſſador extraordinary, he who is laſt arrived has the precedency, unleſs the prince or ſtate by which they are appointed determines their rank differently. When embaſſadors ordinary are relieved, he who is going to quit the court or country where he has reſided walks at the right of his ſucceſſor in proceeding to the audience: but, in returning, he gives the right to the new embaſſador, becauſe his functions are terminated by the farewell audience.

With reſpect to the rank of foreign embaſſadors reſiding at the ſame court among themſelves, the nuncio of the pope was always conſidered as holding the firſt rank at the French court before the eſtabliſhment of the French republic in 1792. He uſed to compliment the king on particular occaſions in the name of the whole diplomatic body. In other courts the French embaſſador had the precedency before the embaſſadors of any other kingdom. The Spaniards alone diſputed his pre-eminence for a time: but it was ſolemnly recognized by Spain in 1662, and no other power did ever diſpute it. The French embaſſador claimed even the precedency before the Ruſſian imperial embaſſador. Mr D'Eſterno, the French embaſſador at the court of Berlin in 1786, found himſelf highly offended, that the queen of Pruſſia, conſort of the late Frederick William II. ſat down to cards with the Ruſſian embaſſador, whilſt he was only invited to take a hand with the princeſs Friderika, eldeſt daughter of the king of Pruſſia, at preſent ducheſs of York.

The right of ſending embaſſadors is generally veſted in the prince or chief magiſtrate, to whom the exerciſe of the executive power is entruſted in independent ſtates. It is an eſſential attribute of ſovereign power. Yet it is not abſolutely neceſſary that a prince be in the actual poſſeſſion of this power to appoint embaſſadors; provided he have not abdicated the crown, his embaſſadors ought to be received at other courts, unleſs there be ſome political motives for refuſing their admiſſion: but even in that caſe they are like other public miniſters, under the ſpecial protection of the public law of nations.

The actual poſſeſſion of the ſovereign power, whatever may have been the means by which it has been acquired, is conſidered as a ſufficient title to the right of ſending embaſſadors, and the embaſſadors of an uſurper have often been admitted in courts where thoſe of the lawful prince have been refuſed. The embaſſadors of Cromwell were received in France, when Charles II. himſelf could not obtain an audience.

To admit an embaſſador, is to acknowledge the ſovereignty of the prince, or the independency of the ſtate which he repreſents. France acknowledged the independence of the United States of America, by admitting Franklin as their embaſſador before they were declared independent by Great Britain.

During the minority of a monarch the regent may appoint embaſſadors, but always in the name of the king. They repreſent him in whom the executive power is veſted by the conſtitution and not his ſubſtitute. It is this repreſentative dignity which ſubjects the proceedings and motions of embaſſadors to formalities and ceremonies that frequently impede and obſtruct their negociations. Hence it is not unuſual to appoint a ſimple miniſter plenipotentiary to carry on an important and difficult negociation, but to furniſh him at the ſame time with the credentials of an embaſſador extraordinary, with the ſtrict injunction not to make any uſe of them unleſs he ſhould be ſucceſsful in his miſſion. In that caſe he delivers them only at the cloſe of the negociation, juſt before the ſigning of the treaty, which derives a certain additional ſolemnity for being ſigned by an embaſſador extraordinary.

As the functions of an embaſſador conſiſt in watching in the country where he is appointed to reſide over the intereſts of the ſtate which he repreſents, in making regular reports of his proceedings, and in communicating every circumſtance, the knowledge of which is deemed of importance to the miniſter at the head of the department for foreign affairs in his own country, it follows that an embaſſador ought to be well acquainted with the political ſtate and

the

the language of the country in which he reſides, with the temper and diſpoſition of the prince or chief magiſtrate by whom it is governed, with the particular character of the miniſter who manages its foreign affairs, with the relations of that country with the other powers of Europe, and with the particular policy which influences them towards that country. To this indiſpenſible political information an embaſſador ought to join a conſummate knowledge of mankind in general, an incorruptible integrity, an enlightened prudence, a ſagacious judgment, mild and refined manners, an inſinuating addreſs, a generous diſpoſition, ſound diſcretion, and dignified firmneſs, and above all a great command over himſelf. This catalogue of qualities, which are rarely combined, ſhews how difficult it muſt be to find fit ſubjects for embaſſies. There is in France a ſort of diplomatic gradation through which all individuals employed in miſſions to foreign courts are generally obliged to paſs. The firſt ſtep is that of ſecretary of legation of the ſecond claſs, then follows that of ſecretary of legation of the firſt claſs; the third ſtep is that of miniſter plenipotentiary, and the fourth that of embaſſador. Frequent exceptions, however, take place with regard to the appointment of embaſſadors, who are ſometimes taken from the army. (Wicquefort. l'embaſſadeur et ſes fonctions. Pecquet. diſcours ſur l'art de négocier. L'eſprit de Leibnitz, tome ii. Cheſterfield's letters ccii. ccxix. clii. cclxxxviii.)

EMBASSADRESS, in French *Ambaſſadrice*, is, in the common acceptation of the word, the wife of an embaſſador, who as ſuch ſhares his rank and privileges. But there have been embaſſadreſſes in their own right, or female embaſſadors. The famous league of Cambray was ſigned, in 1508, on the part of the emperor, by Margaret of Auſtria his daughter, to whom he had given full powers for that purpoſe. The peace concluded at Cambray, in 1529, in confirmation of that of Madrid, was alſo ſigned by the ſame Margaret of Auſtria, ducheſs of Parma, in the name of Charles V. and by Louiſa ducheſs of Savoy, mother of Francis I. by virtue of full powers given to theſe two illuſtrious ladies by the emperor and the king of France. In the year 1645, Louis XIV. expreſſedly appointed Madame la Maréchale de Guébriant his embaſſadreſs extraordinary, to conſign Mary de Gonzagues, daughter of the duke of Nevers, to the arms of her royal huſband, the king of Poland, who had married the princeſs by procuration. Circumſtances might indeed ariſe in which a lady might with great propriety be appointed embaſſadreſs at the court of a ſovereign princeſs, into whoſe confidence ſhe might more eaſily inſinuate herſelf than an embaſſador. In ſuch caſes ſhe would be under the ſpecial protection of the law of nations, and enjoy all the rights and immunities of an embaſſador.

EMBASSY, formerly *Embaſſage*, in French *Ambaſſade*, *legatio*, is the charge or office of an embaſſador, or any other public miniſter ſent to repreſent one ſovereign prince or independent ſtate at the court of another. It alſo denotes the ſolemn meſſage, miſſion, or errand, on which ſuch a public miniſter is ſent.

F. Daniel obſerves, that under the ancient French kings, their embaſſies conſiſted of a body, or number of perſons, joined together in commiſſion, and who compoſed a kind of council; ſomething like which is ſtill retained at treaties of peace. Thus the French embaſſy at Nimeguen, for the peace conſiſted of three plenipotentiaries; that of Utrecht, of two, &c. See EMBASSADOR.

EMBATTLED, a term in *Heraldry*, when the outline of any ordinary is notched ſo as to repreſent the battlements of a wall, or caſtle. See BATTLEMENT.

None were ſuffered, in ancient times, to embattle their houſes, but thoſe who had great dignities, as the barons, and the like. Camden proves this in his account of Tunſtal's ſeat in England, in which he expreſſes it as a ſignal mark of the royal favour, that he had liberty given to embattle it. The heralds expreſs this embattled line by the term *crenelle;* and when it has the embattling on both ſides, which is the more rare, they call it *bréteſſe*; which ſee.

EMBAUL, in *Geography*, a town of Africa, in the kingdom of Damel. N. lat. 15° 15′. W. long. 15° 37′.

EMBDEN. See EMDEN.

EMBELIA, in *Botany*, corrupted from the Ceylon name Aembilla. Burm. Ind. 62. t. 23. Juſſ. 427. (Ribeſioides; Linn. Fl. Zeyl. 190.) Claſs and order, *Pentandria Monogynia*. Nat. Ord. uncertain. *Juſſ.*

Gen. Ch. *Cal.* Perianth ſmall, five-cleft, inferior. *Cor.* Petals five, regular, undivided. *Stam.* Filaments five, equal; anthers . . . . *Piſt.* Germen ſimple, ſuperior; ſtyle one; ſtigma . . . . *Peric.* Berry . . . .

A ſmooth ſhrub, without thorns. *Leaves* alternate, oblong, entire. *Flowers* in terminal panicled cluſters. *Fruit* white, acid, uſed for making rob or jelly. Native of Ceylon. Schreber, by his index, ſeems to refer this plant to *Antideſma*, but their characters do not accord.

EMBER-GOOSE, in *Ornithology*, the *colymbus immer* of Linnæus; which ſee.

EMBER-*weeks*, are thoſe wherein the ember or embering days fall.

In the laws of king Alfred, and thoſe of Canute, theſe days are called *ymbren*, that is, *circular days*, from whence the word was probably corrupted into ember days. By the canoniſts, they are called "quatuor anni tempora," the four cardinal ſeaſons, on which the circle of the year turns; and hence Henſhaw takes the word to have been formed, *viz.* by corruption, from *temper*, or *tempora*. The ancient fathers called them "quatuor tempora jejunii."

Mr. Somner thinks they were originally faſts, inſtituted to beg God's bleſſings on the fruits of the earth. Agreeably to which, Skinner ſuppoſes the word ember taken from the aſhes, embers, then ſtrewed on the head.

The ember days are the Wedneſday, Friday, and Saturday, next after Quadrageſima Sunday, or the firſt Sunday in Lent, after Whitſunday, after Holyrood-day in September, and after St. Lucy's day in December; which four times anſwer well enough to the four quarters of the year, ſpring, ſummer, autumn, and winter. Theſe days are mentioned by Britton, c. 53, and other writers; and particularly in the ſtat. 2 and 3 Edw. VI. c. 19.

Theſe ember weeks are now chiefly taken notice of on account of the ordination of prieſts and deacons; becauſe the canon appoints the ſundays next ſucceeding the ember-weeks for the ſolemn times of ordination; though the biſhops, if they pleaſe, may ordain on any ſunday or holiday.

EMBERIZA, in *Ornithology*, a genus of the Paſſerine order, the character of which conſiſts in the bill being conic; mandibles receding from each other from the baſe downwards, the lower with the ſides narrowed in, and a hard knob within the upper mandible. This laſt-mentioned proceſs in the mouth is adapted in a very peculiar degree to the manners of the emberiza tribe; all the ſpecies feed on ſeeds, and by the aid of this knob they are able to break and comminute the ſhells of the harder kinds with facility. The genus is extenſive, and includes ſome very beautiful birds.

Species.

NIVALIS. Quill-feathers white, primaries black on the outer edge; tail-feathers black, the three lateral ones white. Linn. *Hortulanus nivalis*, Briſſ. *Ortolan de niege*, Buff. *Pied mountain finch*, Albin. *Snow bunting*, Lath. Donov. Brit. Birds.

Inhabits the northern parts of Europe, Aſia, and America, during ſummer, and migrates to warmer climates in the winter. Its ſize rather exceeds that of the chaffinch; it builds in cavities of rocks and lays five eggs, which are of a white colour, ſpotted with brown. The ſpecies varies conſiderably in its plumage at different ſeaſons of the year, and three diſtinct kinds are deſcribed as permanent varieties. One variety is white, with the feathers daſhed with yellow, and the chin and throat marked with very ſmall brown ſpots. This is called by Friſch Weiſs Fleckige Ammer. Another (hortulanus nivalis pectore nigro of Briſſon), is yellowiſh-white above, beneath with the breaſt black; wings and tail black and white intermixed. The pied chaffinch of Albin is the third; the body of this is reddiſh-brown; head and neck white, breaſt with a blueiſh ſpot; wings and tail varied with black and white.

MUSTELINA. Quill-feathers duſky, white at the baſe, the laſt entirely black; tail-feathers black; middle ones at the edge, and three lateral ones each ſide, white with a duſky ſpot without. Gmel. *Emberiza nivalis*, Linn. *Emberiza glacialis*, Lath. *Tawny bunting*, Brit. Zool.

About the ſame ſize as the former, and is by ſome writers erroneouſly confounded as a variety of it. The ſpecies occurs rarely in the northern parts of Britain.

MONTANA. Five firſt quill-feathers blackiſh-brown, the reſt white, ſpotted with brown at the tip; tail-feathers brown; three lateral ones each ſide entirely white. Gmel. *Leſſer mountain brambling*, Willughby. *Mountain bunting*, Lath. Donov. Brit. Birds.

Found in Yorkſhire and Lincolnſhire.

HYEMALIS. Black, belly white. Gmel. *Fringilla hyemalis*, Linn. *Paſſer nivalis niger*, Kalm. *Ortolan jacobin*, Buff. *Snow bird*, Cateſby. *Black bunting*, Lath.

The length of this bird is about ſix inches and a half. During winter, and more eſpecially in ſnowy weather, it is ſeen in Virginia and Carolina; its ſummer place of reſidence is unknown. By ſome it is called the chuck-bird. The fleſh is held in eſteem as an article of food.

MILIARIA. Brown, beneath ſpotted with black; orbits rufous. Linn. *Alaudæ congener*, Aldr. *Strilozzo*, Olin. *Cynchramus*, Briſſ. *Gerſt-ammer*, Gunth. *Le Proyer*, Buff. *Common bunting*, Lath. Donov. Brit. Birds, &c.

Common during the ſummer and autumn in moſt parts of Europe; in England they remain throughout the winter, but in the more ſouthern climates migrate at the approach of that ſeaſon. They aſſociate in flocks. The females build their neſt in a low hedge, or on a ſtump near the ground, and lay from five to ſix eggs. Theſe birds are rather larger than the yellow-hammer, and in the appearance of their plumage ſo cloſely reſemble the lark, that they are commonly ſold under the name of bunting larks in the London markets. They are caught in vaſt numbers for ſale during the winter ſeaſon; the fleſh is bitter, and inferior to that of the true lark.

HORTULANA. Quill-feathers brown, the firſt three whitiſh at the edges; tail-feathers brown, the two lateral ones black on the outer ſide. Linn. *Hortulanus*, Geſn. *Ortolano*, Olin. *Ortolan*, Lath.

The varieties of this ſpecies are numerous; the principal are β (ortolan jaune of Buff.); the plumage of which is yellowiſh, with the quill-feathers edged with white; γ (ortolan blanc) ſnowy white; δ (hortolanus quintus of Ray) which has the tail white; and ε (ortolan noiratre of Buff.) the colour of which is blackiſh, head and neck greeniſh, bill red, and legs cinereous.

Theſe birds are found chiefly in the ſouth of Europe, from whence they migrate northwards as far as Sweden, but have not been known to viſit England. The ſize is that of our yellow-hammer, and its ſong is not very diſſimilar to the notes of that common bird, but more melodious; its neſt is uſually built in a low hedge, or on the ground, and contains five eggs of a greyiſh colour. The celebrity of the ortolan for the tables of epicures is perfectly well known: they are caught for this purpoſe in vaſt number at the times of their periodical migrations in ſpring and autumn, and fattened in a peculiar manner. Their feeders place them in a dark room, with an abundance of oats and millet, upon which they feed with avidity, and become in a very ſhort time extremely fat, in which ſtate they weigh ſometimes three ounces each. When thus fed they are conſidered exquiſitely delicious, and fetch a high price. Ortolans are taken in great numbers in the ſouth of France and Italy, ſome parts of Germany, and the ſouthern provinces of Ruſſia and Siberia; and are potted or otherwiſe preſerved, and form an article of exportation to thoſe countries where theſe delicious birds are leſs commonly found.

SINENSIS. Reddiſh brown, beneath pale yellow; leſſer wing-coverts yellowiſh; quill and tail-feathers with the longitudinal ſtreak on the belly brown. Lath. Ind. Orn. *Ortolan de la Chine*, Sonner. *Chineſe bunting*, Lath.

Inhabits the ſouthern provinces of China during the months of October, November, and December. Size not mentioned.

CITRINELLA. Tail-feathers blackiſh, the two outer ones on the inner edge with a pointed white ſpot. Linn. *Emberiza flava*, Geſn. *Zivolo*, Olin. *Braunt*, Buff. *Yellow-hammer*, Ray. Donov. Brit. Birds.

A general inhabitant of Europe, in every part of which it appears to be common. The male differs from the female in having the colours of the plumage more obſcure, and the head only tinged with yellow; in the male the head is of a very vivid yellow, whence its name. The neſt of this common bird, as is well known, conſiſts of hay, and other dry ſubſtances, ſlightly put together, and placed either on the ground or in a buſh cloſe to it: the eggs from four to five in number, and of a grey colour with ſtreaks, and a few blotches of brown. Theſe birds are eaten in Italy.

OLIVACEA. Olive, beneath whiter; chin orange; pectoral band blackiſh. Gmel. *Emberiza dominicenſis*, Briſſ. *Olive*, Buff. *Olive bunting*, Lath.

Inhabits St. Domingo, and is about the ſize of the common wren.

PASSERINA. Above grey-ferruginous; middle of the feathers black beneath, whitiſh-aſh ſpotted on the ſides; tail-feathers black, the middle ones edged with ferruginous; the outer one each ſide nearly to the baſe, the next as far as the middle obliquely white. Pallas. *Paſſerine bunting*, Lath.

Size of the reed ſparrow. The head and chin in the male black; behind the eyes a pale ſtreak; tail rather forked; legs browniſh fleſh colour. Inhabits Ruſſia near the Ural, and Jaick.

PUSILLA. Above grey-ferruginous; beneath whitiſh; throat ſpotted; head with alternate longitudinal teſtaceous and black bands. Pallas.

A ſmall ſpecies, found among the ſnowy mountains of Dauuria.

RUSTICA. Head black, with three longitudinal white bands, chin, body beneath, and two outmoſt tail-feathers each ſide obliquely white. Pallas.

Inhabits Dauuria, chiefly in woody ſituations.

FUCATA. Grey-ferruginous; ears with a round rufous ſpot; eye-brows, line beneath the eyes and throat white; chin ſurrounded with a brown ſpotted circle. Pallas.

Frequent in rocky parts of Siberia.

SPODOCEPHALA. Grey-ferruginous, beneath pale ſtraw colour; frontlet black; head and neck hoary-aſh. Pallas.

Inhabits near the waterfalls in the Alpine regions of Dauuria. Size of the reed bunting.

CHRYSOPHRYS. Grey-ferruginous; crown black; eye-brows citron, from the middle of the crown to the nape a white band. Pallas.

Found with the latter; ſize of the common yellow-hammer.

MAELBYENSIS. Head and neck lead-cinereous; chin whitiſh; belly ferruginous. Sparrman, Muſ. Carl.

Deſcribed from a ſpecimen taken at Maelby, in Sweden, a ſeat of count Carlſon, in the dukedom of Sudermania. Some writers ſuggeſt that the bird mentioned might be either the female or young of the pine bunting.

RUTILA. Sanguineous rufous; beneath ſulphur; wings grey ruſty. Pallas.

Inhabits Siberia, and is the ſize of the yellow-hammer.

FERRUGINEA. Ferruginous; belly, and two ſpots on the primary quill-feathers, white. Arct. Zool. *Ruſty bunting*, Lath.

Native of North America.

AMERICANA. Above cinereous, ſtreaked with brown; beneath yellow; chin white; quill and tail-feathers black, with pale edges. Gmel. *Black throated bunting*, Arct. Zool.

Found in New York. Size of the yellow-hammer. The female is like the male, but has no black ſpot on the throat, nor ſtreak of yellow above the eye. Dr. Latham deſcribes a variety met with in Hudſon's bay, the colour of which is aſhy brown, beneath whitiſh, front and eyebrows yellow; band under the eyes, and the creſcent on the front, black; chin, as in the male of the other, with a triangular black ſpot in the middle.

BRASILIENSIS. Crown, neck, and body beneath, yellow; back, wings, and tail greeniſh, varied with yellow and brown. Gmel. *Guiram heemgata*, Ray. *Guirnegat*, Buff. *Braſilian bunting*, Lath.

Size of a ſparrow. The ſpecies inhabits Brazil.

MEXICANA. Above browniſh, beneath whitiſh, ſpotted with brown; head and throat yellow. Gmel. *Théreſe jaune*, Buff. *Mexican bunting*.

Length ſix inches and a half; the legs and bill pale; wings and tail browniſh. Native of New Spain.

MILITARIS. Head, wings, tail, and back brown; lower part of the back and breaſt yellow; ſhoulders greeniſh; belly white. Haſſelq. *Military bunting*, Lath.

Inhabits Malta.

MELANOCEPHALA. Yellow, head black; back rufous. Scop. *Black-headed bunting*, Lath.

Size of the yellow-hammer, and inhabits Europe.

BRUMALIS. Body beneath; front and region of the eyes citron; hind head and neck cinereous. Scop.

Native of the Tyroleſe country. This and the two following are ſmall ſpecies.

COCCINEA. Body above ſilvery, beneath crimſon; vent white; bill, head, and quill-feathers black; hind head and tail black-blue. Sander.

Found in the woods about Baden.

BADENSIS. Olive, ſtriated with blackiſh, beneath paler; throat orange; breaſt with black ſtreaks. Sander.

Inhabits Baden. The bill is black above, beneath yellowiſh, with a ſingle obtuſe tooth in the middle.

ERYTHROPHTHALMA. Black, with a red gloſs; belly reddiſh; wings with a white ſpot. Gmel. *Fringilla Carolinenſis*, Briſſ. *Towhee bird*, Cateſby.

This ſpecies inhabits Carolina, frequents ſhady woods, and is generally ſeen in pairs. Called by ſome the American bulfinch. Length eight inches.

LEUCOPHRYS. Ruſty brown, beneath white; vent yellow; crown black, with a white fillet in the middle; eye-brows white. Forſt. *White crowned bunting*, Arct. Zool.

Inhabits Canada, feeds on graſs, ſeeds, and worms, ſings melodiouſly, and lays three or four chocolate-coloured eggs. Length rather exceeding ſeven inches.

LUCTUOSA. Black; beard on the cheſt, front, breaſt, belly, rump, and vent white. Scop. *Wreathed bunting*, Lath.

Size of the greater titmouſe.

AUREOLA. Rufous, beneath yellow; tranſverſe pectoral band ferruginous; crown, cheeks, and chin black. Pallas. *Emberiza Sibirica*. Lepechin. *Yellow breaſted bunting*. Lath.

Size of the reed ſparrow, and inhabits the pine groves of Siberia.

SANDWICHENSIS. Brown, beneath whitiſh, ſpotted with brown; eye-brows yellow; temples duſky. Gmel. *Unalaſha bunting*, Arct. Zool. *Sandwich bunting*, Lath.

Length ſix inches; bill and legs black; under the eyes a duſky line; middle of the belly whitiſh and immaculate. Native of Sandwich bay.

AOONALASCHKENSIS. Reddiſh brown; beneath whitiſh, ſtreaked with brown; middle of the belly white. Gmel.

Length ſeven inches, inhabits Aoonalaſchka, and reſembles the former.

ATRICAPILLA. Cheſnut, beneath cinereous; chin white; crown pale yellow, front and ſtreak through the eyes to the nape black. Gmel. *Black crowned bunting*, Lath.

Native of the Sandwich iſlands; its neck is ſeven inches, the bill black, and legs brown. A variety is deſcribed in Cook's laſt voyage, which has the breaſt waved with black; the female without the yellow ſpot on the crown.

PITHYORNUS. Middle of the crown with an oval white ſpot; nape varied with white; chin red-teſtaceous; two exterior tail-feathers, each ſide with an oblique white band. Pallas. *Emberiza leucocephala*, S. G. Gmelin. *Emberiza alia ſpecies*, Lepechin. *Pine bunting*, Lath.

Inhabits the pine foreſts of Siberia, from the Uralian chain of mountains to the Lena; it lives among reeds on the ſhores of rivers, and paſſes the winter ſometimes on the borders of the Caſpian ſea. The ſize is that of the yellow-hammer, and it has the note of the reed ſparrow.

CINEREA. Bay, beneath whitiſh, ſpotted with bay; tail and quill-feathers brown, edged with grey; rump grey; tail-coverts reddiſh white. Gmel. *Emberiza canadenſis*, Briſſ. *Cul-rouſſet*, Buff. *Cinereous bunting*, Arct. Zool.

Length five inches and a half, and inhabits the juniper woods in Canada.

CÆRULEA. Rufous and blue varied; crown rufous;

greater wing-coverts, quill-feathers, and tail-feathers, brown, with the outer edge rufous. Gmel. *Emberiza canadenſis cærulea*, Briſſ. *Azuroux*, Buff. *Blue bunting*.

Inhabits Canada, and rarely New England. Its length is four inches and a half.

Cyanea. Blue; crown deeper; quill, and tail-feathers brown edged with blue. Lath. Ind. Orn. *Emberiza cyanea, rectricibus fuſcis*, Gmel. *Tanagra cyanea*, Linn. *Miniſtre*, Buff. *Blue linnet*, Cateſby. *Indigo bunting*, Lath.

Size of the ſiſkin. The male, when in full plumage, is blue, at other times reſembles the female, which is nearly throughout of a browniſh colour; in the latter, however, the edge of the wing is tinged with green, and by this peculiarity the female may be diſtinguiſhed from the male, the edge of his wing being blue. In Carolina, the inland parts of which this ſpecies inhabits, it is called the parſon, and by ſome the biſhop; and the Spaniards at Mexico, which country it inhabits, alſo name it azul lexos, or "far-fetched blue bird." It feeds on ſeeds, and is ſaid to have the note of the common linnet.

Cyanella. Shining blue-interſcapulars and ſhoulders varied with blue and rufous; quill and tail-feathers edged with blueiſh. Sparrm. Muſ. Carlſ. *Emberiza cyanella*, Gmel. *E. cyanea*, β Lath.

Deſcribed by Sparrman as a ſpecies. Gmelin admits it with doubt, and Latham conſiders it as a variety only of cyanea; it is a native of North America.

Quelea. Grey; front black; bill ſcarlet. Gmel. *Moineau à bec rouge du Sénégal*, Buff. *Black faced bunting*, Lath.

The bill of this bird is thick; cheeks and chin black; reſt of the head, ſhoulders, and back varied with black and grey; breaſt and belly reddiſh white; quill and tail-feathers blackiſh, edged with cinereous. The ſpecies inhabits Senegal, and is four inches and a half in length. The female reſembles the male, but wants the black about the head. The bird deſcribed by Buffon, under the name of Moineau du Senegal, is conſidered as a variety.

Tetrix. Cheſnut, beneath yellow; eye-brows and rump yellow; middle of the head and breaſt with a broad black band. Gmel. *Weaver bunting*, Lath.

Size of the houſe ſparrow, which bird it reſembles in the browniſh colour of the plumage during winter. The name of weaver bunting was given to this bird from its propenſity to interweave ſilk between the wires of its cage, like the weaver oriole, and, it is conjectured, the neſt of the weaver bunting is compoſed in a manner ſomewhat ſimilar to that of the above-mentioned oriole, which conſiſts of leaves curiouſly ſewed together with the filaments of plants. This bird inhabits Africa.

Rubra. Crimſon; neck and back varied with olive and black, and a few crimſon marks; belly and vent cinereous; quill and tail feathers black, edged with grey-green. Gmel. *Moineau de l'iſle de France*, Buff. *Crimſon bunting*, Lath.

Size of the laſt, and inhabits the iſle of France. The bill is black; legs pale fleſh colour; female olive and paler beneath.

Capensis. Grey; throat whitiſh; ocular band and another beneath blackiſh. *Hortulanus capitis Bonæ Spei*, Briſſ. *Ortolan du Cap de Bonne Eſperance*, Buff. *Cape bunting*, Lath.

Native of the Cape, and in ſize reſembles the ſparrow. Three varieties of this ſpecies are deſcribed in Buffon's "Planches Enluminees," namely, β, the body of which is yellow beneath, and the ſides of the head and neck marked with three black ſtripes; γ, having the body beneath whitiſh; and δ, which is whitiſh beneath, and has the throat varied with cinereous. The two firſt of theſe are conceived to be merely varieties of the Cape kind, the laſt is a native of Cayenne, where, according to Buffon, it is called *Bonjour-commandeur*, from being accuſtomed to commence its ſong at the break of day.

Fusca. Browniſh; wings and tail brown with duſky bands; belly white; noſtrils, cheeks, and chin with feathered tufts. Gmel. *Barred-tailed bunting*, Lath.

Deſcribed by Dr. Latham from a figure met with among ſome Chineſe drawings. The ſize is ſaid to be that of the common bunting. The beak is fleſh-coloured; legs roſy.

Ludovicia. Rufous ſpotted with black; beneath pale; breaſt rufous; head with a black creſcent. Gmel. *Hortulanus ludovicianus*, Briſſ. *Ortolan de la Louiſiane*, Buff.

Length five inches and a quarter. The bill rufous ſpotted with black, head and throat reddiſh; rump and cuneated tail black; breaſt rufous; legs cinereous. Native of Louiſiana.

Cia. Reddiſh; head with a few blackiſh lines; eye-brows white. *Emberiza barbata*, Scop. *Emberiza pratenſis*, Geſn. *Bruant fou*, Buff. *Bruant de ſprés*, Buff. *Fooliſh bunting*, Lath.

Native of the warmer parts of Europe, and delights moſt in mountainous ſituations; it is a ſilly bird, and eaſily caught in any ſnare, whence its name; its note is only a repetition of ſounds, like the pronunciation of the words zi-zi-zi-zip-zip. The Genoeſe call it Cia montanina.

Cirlus. Fuſcous; breaſt ſpotted; eye-brows pale yellow; two outmoſt tail-feathers with a white cuneated ſpot. Gmel. *Emberiza ſepiaria*, Briſſ. *Cirlus*, Aldr. *Cirl bunting*.

Size of the yellow-hammer, and inhabits Italy and France; the ſpecies has been lately found in Britain.

Familiaris. Cinereous ſpotted with brown; tail-feathers white at the tip; hind part of the back yellow. Gmel. *Bruant familier*, Buff. *Familiar bunting*.

Oſbeck deſcribes this ſpecies under the name of Motacilla familiaris. This writer ſpeaks of it as a docile bird, and ſays, if the cage-door was opened it would jump out upon the perſon's hand who releaſed it, and if any one whiſtled in its hearing, it ſang ſweetly in return. If a diſh of water was placed before it, the bird inſtantly plunged into it, and bathed itſelf. It was fed with rice.

Flaveola. Grey; face yellow. Gmel. *Flaveole*, Buff. *Yellow-faced bunting*.

Native of warm climates, and very ſmall.

Amazonia. Brown; crown fulvous; vent whitiſh. Gmel. *Amazone*, Buff. *Amazon bunting*.

Size of the titmouſe, and inhabits Surinam.

Oryzivora. Black; crown reddiſh; belly black; tail-feather daggered. Gmel. *Agripenne ou Ortolan de riz*, Buff. *Rice bird*, Cateſby. *Rice bunting*, Arct. Zool.

About the ſize of the ſparrow. The ſpecies is confined to the continent of America, and is of the migratory kind, paſſing in flocks at particular ſeaſons from one part to another. The Americans call it Bob Lincoln and Conquedle. Its food conſiſts of grain and inſects, and the maize eſpecially; they are remarkably fond of this plant, and prove highly deſtructive to the crops, by unneceſſarily perforating the huſks after ſatisfying their appetites, and thus leaving openings through which the rain penetrates, and effectually deſtroys the plants. Some, for this reaſon, call it the maize thief, or white backed maize thief. Its note is much admired. There is a variety of this bird of an olive-brown colour, beneath yellowiſh; rump yellow, tranſverſely lined with brown; greater wing-coverts and quill-feathers edged with white.

Schoeniculus. Head black; body grey and black; outmoſt tail-feathers with a white wedged ſpot. Linn Fn. Suec. *Junco turneri*, Geſn. Buff. *Reed bunting*, Lath.

Native of Europe and the ſouthern parts of Siberia. The female differs from the male in having the head browniſh inſtead of black.

Lesbia. Beneath white; face white with three black bands; breaſt and rump browniſh; tail-feathers white, the two middle ones duſky, edged with rufous. Gmel. *Mitilene de Provence*, Buff. *Leſbian bunting*, Buff.

Length about four inches and a half; it inhabits Provence, where it is called Chic de Mitilene, being rare in that part, and known to be common in the Greek iſle Mitylene, or Leſbos. They are ſaid to exert a peculiar kind of ſcream on the approach of any bird of prey, a circumſtance which the Greeks turn to ſome advantage, for they place one or more of theſe birds incloſed in ſtrong iron cages in their poultry yards, and the approach of the hawk, or any other bird of prey, is loudly announced by theſe little centinels the moment it appears in ſight; and by this means the poultry are allowed ſufficient time to effect their eſcape.

Provincialis. Beneath white; band acroſs the eyes and on the wing and chin white; ſpot under the eyes, ſtreak each ſide the chin, and breaſt browniſh ſpotted with black; quill and tail-feathers duſky, edged with rufous. Gmel. *Gavoué de Provence*, Buff. *Muſtachoe bunting*, Lath.

Size of the laſt, and inhabits Provence.

Lotharingica. Spotted with black; above rufous, beneath cinereous, abdomen rufous; ſtreak acroſs the eyes and on the mandibles black; tail-feathers black and white, middle ones rufous; exterior ones nearly all white. Gmel. *Ortolan de Lorraine*, Buff. *Lorrain bunting*.

Inhabits Lorrain; the female is white beneath, and has a whitiſh ſpot above and a rufous one beneath the eyes. Length ſix inches and a half.

Psittacea. Browniſh-aſh; wings tawny; two tail-feathers very long. Gmel. *Fringilla braſilienſis*, Seba. *Veuve éteinte*, Buff. *Pſittaceous bunting*, Lath.

Size of a ſparrow, and inhabits Braſil.

Paradisea. Black; breaſt red; four middle tail-feathers long, and pointed; two very long, bill black. Scop. *Vidua*, Briſſ. *Indian long-tailed ſparrow*, Will. *Red-breaſted long-tailed finch*, Edw. *Whidah bird*, Lath.

Native of Angola in Africa.

Serena. Head black; crown red; tail cuneated; two middle tail-feathers very long; legs grey. Gmel. *Vidua minor*, Briſſ. *Veuve dominicaine*, Buff. *Dominican bunting*, Lath.

Like the reſt of the long-tailed buntings, this bird is deſtitute of the two long tail-feathers during winter, and changes its plumage twice in the year.

Vidua. Blackiſh; beneath whitiſh; four middle tail-feathers long and pointed, two of them very long; bill red. Gmel. *Vidua major*, Briſſ. *Grande veuve*, Buff. *Long-tailed ſparrow with a ſcarlet bill*, Will.

The body of this ſpecies is leſs than that of the ſparrow; the ſpecies inhabits Angola in Africa and India.

Principalis. Variegated; breaſt rufous; four middle tail-feathers very long; bill and legs red. Gmel. *Vidua angolenſis*, Briſſ. *Variegated bunting*, Lath.

Inhabits Angola.

Regia. Middle tail-feathers very long, equal, feathered only at the tip; bill red. Gmel. *Veuve à quatre brins*, Buff. *Shaft-tailed bunting*, Lath.

Inhabits the maritime parts of Africa. Length four inches and a half. The body above and vent black; throat, temples, orbits, and body beneath rufous; legs red.

Longicauda. Black; ſhoulders orange, edged with white; tail-feathers long, the ſix middle ones very long. Gmel. *Veuve à épaulettes*, Buff. *Yellow-ſhouldered oriole*, Brown.

Native of the Cape of Good Hope.

Panayensis. Black; breaſt with a large ſcarlet ſpot; four middle tail-feathers very long, pendulous, pointed and equal. Gmel. *Veuve en feu*, Buff. *Veuve de l'iſle de Panay*, Sonnerat. *Panayan bunting*.

Inhabits the iſle of Panay.

Angolensis. Black; crown and collar yellow; tail long. Gmel. *Gros-bec à poitrine couleur de feu*, Salerne. *Angola bunting*.

Size of a finch, and inhabits Angola.

Ciris. Head bule; abdomen fulvous; back green; feathers green brown. Gmel. *Painted finch*, Cateſby. *China bulfinch*, Albin. *Painted bunting*, Arct. Zool.

Length five inches and a half, varies in colour, and inhabits South America; they build in the orange trees, and feed on plants of various kinds. In Holland, and ſome other parts of Europe to which they have been tranſported, they are reared in cages like the Canary with us, and are ſaid to live eight or ten years in this ſtate of captivity.

Quadricolor. Head and neck blue; back, wings, and tail at the tip green; tail and abdomen in the middle red; breaſt and remainder of the belly browniſh. Gmel. *Groſbeak de Java*, Buff. *Red rump bunting*, Lath.

Native of Java. Length five inches.

Cyanopis. Green; rump and abdomen rufous; front, cheeks and chin blue; quill-feathers brown, edged with green; tail-feathers edged with red; middle ones green, the reſt brown. Gmel. *Chloris javenſis*, Briſſ. *Toupet bleu*, Buff. *Blue faced bunting*, Lath.

Length four inches; inhabits ſame country as the laſt.

Viridis. Above green; beneath white; wings and tail blue. Gmel. *Chloris indica minor*, Briſſ. *Parement bleu*, Buff. *Green bunting*, Lath.

Size of a ſparrow; the bill greeniſh brown; ſhafts of the quill and tail-feathers white; and legs black. Native of India.

Platensis. Above greeniſh-brown; beneath whitiſh-aſh; back varied with black; quill, and lateral tail-feathers edged with yellow. Gmel. *Emberiſe à cinq couleurs*, Buff. *Plata bunting*, Lath.

Length eight inches. This ſpecies inhabits near the river Plata in South America.

Borbonica. Rufous red; wings, tail, and legs cheſnut. Gmel. *Mordoré*, Buff. *Bruant de l'iſle de Bourbon*, Buff. *Bourbon bunting*.

Inhabits the iſle of Bourbon.

Calfat. Hoary; beneath vinaceous; head, chin, and edge of the tail black; bill and orbits roſy. Gmel. *Calfat*, Buff. *Red-eyed bunting*, Lath.

Leſs than the common ſparrow, and inhabits the iſle of France.

Chlorocephala. Fuſcous; head and neck olive; back and wing-coverts varied with brown and black; tail forked. Gmel. *Green-headed bunting*. Brown's illuſtr.

A very ambiguous kind; probably an accidental variety of ſome European bunting. The bird deſcribed was caught in Mary-le-bone fields, and preſerved in the Tunſtal Collection.

Grisea. Grey; wing-coverts and breaſt varied with red; quill and tail-feathers within white, without varied with grey and red. Gmel. *Emberiza Surinamenſis*, Briſſ. *Gonambouch*, Seba. *Grey bunting*, Lath.

Inhabits Surinam, where it is common, and its note is ſaid to be equal to that of the nightingale. Its food is chiefly maize. The natives call it gonambucho.

Surinamensis. Grey, beneath pale-yellow; breaſt with oblong black ſpots. Gmel. *Prayer*, Fermin. *Surinam bunting.* Lath.

Rather larger than the lark. Inhabits Surinam.

Ruficapilla. Body above fuſcous, beneath cinereous; chin ferruginous; frontlet white; above reddiſh; tail black. Sparm. Muſ. Carlſ.

Asiatica. Cinereous; wings and tail brown. Lath. Ind. Orn. *Gaur bunting.*

Inhabits the Eaſt Indies, where it is known by the name of gaur.

EMBLEM, Εμϐλημα, a kind of painted ænigma, which, repreſenting ſome obvious hiſtory, with reflections underneath, inſtructs us in ſome moral truth, or other matter of knowledge.

The word is pure Greek, formed of the verb εμβαλλειν, *to caſt in, to inſert.* Suetonius relates, that Tiberius cauſed the word to be eraſed out of a decree of the Roman ſenate, becauſe it was borrowed from another language.

Such is that very ſignificant image of Scævola, holding his hand in the fire; with the words, "agere & pati fortia, Romanum eſt:" "to do and ſuffer courageouſly is Roman."

The emblem is ſomewhat plainer, and more obvious, than the *ænigma;* which ſee. Gale defines emblem an ingenious picture, repreſenting one thing to the eye, and another to the underſtanding.

The Greeks alſo frequently gave the name emblems, εμϐληματα, to inlaid or moſaic works, and even to all kinds of ornaments of vaſes, moveables, garments, &c. And the Latins uſed emblema in the ſame ſenſe. Accordingly, Cicero, reproaching Verres with the ſtatues and fine wrought works he had plundered from the Sicilians, calls the ornaments fixed thereto (and which, on occaſion, might be ſeparated from them) emblemata. Add, that Latin authors frequently compare the figures and ornaments of diſcourſe to theſe emblemata: thus, an ancient Latin poet, praiſing an orator, ſays, that all his words were ranged like the pieces in moſaics,

> "Ut teſſerulæ omnes,
> Arte pavimenti, atque emblemate vermiculata."

We do not uſe the Engliſh word emblem in this ſenſe; though the ancient juriſconſulti always retain the Latin emblema to expreſs ſuch ornaments; becauſe the Greek εμϐλημα literally denotes any thing applied, or added to a body by way of enrichment.

With us, emblem ordinarily ſignifies no more than a painting, baſſo relievo, or other repreſentation, intended to hold forth ſome moral or political inſtruction.

What diſtinguiſhes an emblem from a device is, that the words of an emblem have a full, complete ſenſe of themſelves; nay, all the ſenſe and ſignification which they have together with the figure. But there is yet a farther difference between emblem and device; for a device is a ſymbol appropriated to ſome particular perſon, or that expreſſes ſomething which concerns him particularly; whereas an emblem is a ſymbol that regards all the world alike.

Theſe differences will be more apparent from comparing the emblem above quoted with the device of a candle lighted; and the words, "juvando conſumor," "I waſte myſelf in doing good." See Device.

According to lord Bacon, emblems are of uſe in the art of memory, as ſenſible objects ſtrike the mind ſtronger than what is intellectual. Thus, it is eaſier to retain the image of a ſportſman hunting a hare, of an apothecary ranging his boxes, an orator making a ſpeech, a boy repeating verſes, or a player acting his part, than the correſponding notions of invention, diſpoſition, elocution, memory, and action. Works abr. vol. i. p. 136. vol. ii. p. 475. and vol. iii. p. 106.

Emblems, *Hagiographical.* The ſtatues and pictures of the apoſtles, martyrs, and other ancient ſaints, are diſtinguiſhed by their reſpective emblems. Theſe appear to have been fixed upon by the artiſts of the 12th and 13th centuries. Sometimes they repreſent the inſtruments of their death or torments, as the Burgundy croſs of St. Andrew, the gridiron of St. Laurence, the cardine comb of St. Blaſe, the wheel of St. Catharine; at other times they relate to ſome circumſtances in the life or legend of the ſaint, as the organ of St. Cecily, the dove of St. Gregory the Great; frequently they bear alluſion to the name of the holy perſonage, as the lamb of St. Agnes, the gigantic ſtature of St. Chriſtopher, bearing the infant Chriſt upon his ſhoulders.

EMBLEMATICAL Characters. See Character.

EMBLEMENTS, *Fr.* from *emblaver*, q. d. *ſemer en blé*, to ſow with wheat, a term ſtrictly ſignifying the profits of lands ſown; though ſometimes uſed more largely for any profits ariſing, and growing naturally from the ground; as graſs, fruit, &c.

If a tenant for life ſow the land, and die before harveſt, his repreſentatives ſhall have the emblements to compenſate for the labour and expence of tilling, manuring, and ſowing the lands, and alſo for the encouragement of huſbandry; and not he in reverſion. But if the tenant for years ſow the land, and before ſeverance the term expires, or the eſtate for life be determined by the tenant's own act, as by forfeiture for waſte committed, or if a tenant during widowhood thinks proper to marry, there the leſſor, or he in reverſion, ſhall have the emblements, and not the leſſee.

The advantages of emblements are particularly extended to the parochial clergy by 28 Hen. VIII. cap. 11.

All the caſes of emblements turn upon the point of uncertainty; ſince the tenant could not poſſibly know when his landlord would determine his will, and therefore could make no proviſion againſt it; and having ſown the land, which is for the good of the public, upon a reaſonable preſumption, the law will not ſuffer him to be a loſer by it. But it is otherwiſe, and upon reaſon equally good, where the tenant himſelf determines the will; for in this caſe, the landlord ſhall have the profits of the land. (Co. Litt. 55, 56.) Theſe emblements are diſtinct from the real eſtate in the land, and are ſubject to many, though not all, the incidents attending perſonal chattels. They were deviſable by teſtament before the ſtatute of wills (Perk. § 412.); and at the death of the owner, ſhall veſt in his executor, and not his heir; they are forfeitable by outlawry in a perſonal action (Bro. Abr. tit. emblements, 21. 5 Rep. 116.); and by the ſtatute 11 Geo. II. c. 19. though not by common law (1 Roll. Abr. 666.), they may be diſtrained for rent arrear. Although the emblements are aſſets in the hands of the executor, are forfeitable upon outlawry, and diſtrainable for rent, they are not in other reſpects conſidered as perſonal chattels; and particularly, they are not the object of larciny, before they are ſevered from the ground. (3 Inſt. 109.)

EMBLICA, in *Botany*, Gærtn. t. 108. f. 2. See Phyllanthus and Myrobalanus.

EMBODY, in the *Military Art*. To *diſembody*, relates to the ſeparation of thoſe individuals forming a regiment, &c. when its ſervices are no longer required. This term is totally diveſted of that diſgrace which is conveyed under the terms *diſmiſſed*, or *broken*. Thus we find, that, during times of danger, the militia are called out; and on the return of peace, that orders are iſſued for their being "diſembodied." Hence, in that admirable ſatire, "the Mayor of Garrat," major Sturgeon ſays, "Our corps is diſembodied, ſo the French may ſleep in ſecurity."

When a regiment is diſembodied, or, in other words, diſbanded, (though the latter term is often, but erroneouſly, intended to convey reproach,) the arms are lodged in the proper ſtore-rooms; and every thing is numbered or ticketted, in order that when the regiment may again be called out, all may be in readineſs for its equipment.

EMBOLE, in *Surgery*, the reduction or ſetting of a diſlocated bone. The term is derived from the Greek εμβαλλειν, *to put in*.

EMBOLI, in *Geography*, a town of European Turkey, in the province of Romania, a colony from Athens. It is called by the Chriſtians "Chriſtopolis," but is little better than a heap of ruins; 48 miles E. of Saloniki.

EMBOLIMA, in *Ancient Geography*, a town of India, on this ſide of the Ganges. It was ſituated S.W. of Petra Aornos, upon the right of the Indus, and N. of Taxila.

EMBOLIMÆAN and Embolismic, *Intercalary*, is chiefly uſed in ſpeaking of the additional months which chronologiſts inſert to form the lunar cycle of 19 years.

The 19 ſolar years, conſiſting of 6939 days, and 18 hours; and the 19 lunar years only making 6726 days; it was found neceſſary, in order to render the 19 lunar years equal to the 19 ſolar, which make the lunar cycle of 19 years, to intercalate or inſert 7 lunar months, containing 209 days; which, with the 4 biſſextile days happening in that interval, make 213 days, and the whole, 6939 days. See Cycle.

By means of theſe ſeven emboliſmic, or additional months, the whole 6939 days and 18 hours of the ſolar years are employed in the calendar.

In the courſe of 19 years there are 228 common moons, and 7 emboliſmic moons. Their diſtribution is thus: every 3d, 6th, 9th, 11th, 14th, 17th, and 19th, years, are emboliſmic, and conſequently contain 384 days a-piece. And this was the method of computing time among the Greeks, when they uſed the enneadecæterides, or cycle of 19 years. But they did not keep regularly to it, as the Jews ſeem to have done. The Greeks were followed by the Romans till the time of Julius Cæſar.

The emboliſmic months, like other lunar months, are ſometimes 30 days, and ſometimes only 29. See Year.

The emboliſmic epacts are thoſe between XIX and XXIX; which are thus called, becauſe, with the addition of the epact XI, they exceed the number XXX: or rather, becauſe the years, which have theſe epacts, are emboliſmic; having 13 moons a-piece, whereof the 13th is the emboliſmic.

EMBOLISMUS, Εμβολισμος, in *Chronology*, ſignifies intercalation.

The word is formed of εμβαλλειν, *to inſert*. See Embolismic.

As the Greeks made uſe of the lunar year, which is only 354 days, in order to bring it to the ſolar, which is 365 days, they had every two or three years an emboliſm, *i. e.* they added a thirteenth lunar month every two or three years; which additional month they called embolimæus, εμβολιμαιος, becauſe inſerted, or intercalated.

EMBOLUS, the immoveable part of a pump, or ſyringe; called alſo the *piſton*, and popularly the *ſucker*. See Piston, Pump, and Syringe.

The pipe, or barrel of a ſyringe, &c. being cloſe ſhut, the embolus cannot be drawn up without a very conſiderable force; which force being removed, the embolus returns again with violence. This phenomenon the Ariſtotelians attribute to nature's abhorrence of a vacuum.

But the modern philoſophers finding, that in an exhauſted receiver the embolus is eaſily drawn up, though the orifice be ſtopped, prove that it is the preſſure of the atmoſphere on the external parts of the embolus, that makes the difficulty of drawing it up. See Air, Atmosphere, and Suction.

EMBORDERED, in *Heraldry*, a term applied to a border, when it is of the ſame metal, colour, or fur, with the arms.

EMBORISMA, an aneuriſm.

EMBOSSING, or Imbossing, the act of forming, or faſhioning works in relievo, whether they be caſt, or moulded, or cut with the chiſſel, &c.

Emboſſing is one great part of ſculpture; being that which has to do with figures raiſed, or prominent from the plain, or ground; the other part, which makes figures, &c. that are indented, or cut in below the ground, is called engraving. See Enchasing.

Embossing, or *Imboſſing*, in *Architecture*, is that kind of ſculpture wherein the figure is made to ſtand in relief beyond a plane or naked from which it ſeems to riſe. It has three denominations, according to the degree with which it riſes from the ſurface, as baſſo-relievo, mezo-relievo, alto-relievo; or low-relief, mean-relief, high-relief.

EMBOTHRIUM, in *Botany*, ſo named by Forſter from εν, *in*, and Βοθριον, a *little pit*, or *hollow*, alluding to a ſmall cavity towards the point of each petal, in which the almoſt ſeſſile anthers are ſeverally placed. Forſt. Gen. 8. t. 8. Linn. fil. Suppl. 16. Schreb. 62. Willd. Sp. Pl. v. 1. 537. Juſſ. 79. Mart. Mill. Dict. v. 2. Sm. Bot. of N. Holl. 19—29. t. 7—10. Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Proteaceæ*.

Gen. Ch. *Cal.* none. *Cor.* Petals four, cohering by their lower part into a tube, linear, oblique, at length revolute; their ſummits dilated, concave, bearing the ſtamens. *Stam.* Filaments four, very ſhort, inſerted into the hollow in the tip of each petal; anthers rather large, kidney, or heart-ſhaped. *Piſt.* Germen ſuperior, ſtalked, linear, aſcending, inflexed; ſtyle incurved; ſtigma large, obtuſe, lateral. *Per.* Follicle ſtalked, ſomewhat cylindrical. *Seeds* in two rows, imbricated, compreſſed, each with a membranous wing, generally numerous.

Eſſ. Ch. Petals four. Stamens inſerted into the limb. Follicle containing ſeveral winged ſeeds.

This is a fine genus of the Proteaceous order, chiefly found in New Holland. One of the two original ſpecies, indeed, E. *coccineum*, Linn. Suppl. 128, Cav. Ic. v. 1. 47. t. 65, grows on the cold hills bordering the ſtraits of Magellan, even in Terra del Fuego. Yet this appears by Commerſon's and Forſter's ſpecimens to be a very handſome ſhrub, with all the air of a North American *Kalmia* or *Rhododendron*. The *leaves* are elliptical and entire, ſmooth, pale beneath. *Flowers* ſcarlet, in a denſe terminal cluſter, with ſmall linear *bracteas*. *Follicle* ſhort, and rather ſemi-ovate.

E. *ſpecioſiſſimum*, Sm. Bot. of New Holland 19, t. 7, is a ſtill finer ſpecies, a native of New South Wales, where the natives call it Waratàh. Living plants were ſent many years ago to the dowager lady de Clifford. This is remarkable for the numerous large ſcarlet *bracteas*, which envelop its denſe ſpike of the ſame colour. The *leaves* are obovate and ſerrated, remarkably obtuſe.

E. *ſilaifolium*, Sm. Bot. of N. Holland, 23. t. 8. flowered at Mr. Grimwood's nurſery, Kenſington, in 1792, being forced in the ſtove. It comes alſo from New South Wales, and has finely divided rigid *leaves*, with looſe ſpikes of white *flowers*.

E. *ſericeum*, ibid. 25. t. 9, and ſome of its varieties are now not rare in the greenhouſes about London. See Curt. Mag. t. 862, and Andr. Repoſ. t. 100 and t. 272.

Mr. R. Brown, in paper on *Proteaceæ*, read laſt winter before the Linnæan Society, has new-modelled and greatly ſubdivided the genus *Embothrium*, he having had opportunities of ſtudying its ſpecies alive in their native ſituations, which no other botaniſt has ſo fully enjoyed.

EMBOUCHURE, a French term in *Muſic*, literally the hole in the upper joint of a German flute, in which the performer breathes; but when it is ſaid that a flute player has a good embouchure, it means that his tone is good.

EMBOUL, in *Geography*, a town of Africa, in the country of Senegal.

EMBOWELLING Alive, in *Law*, is part of the puniſhment of high treaſon.

EMBRACE *a* Volt, in the *Manege*, is uſed when a horſe, in working upon volts, makes a good way every time with his fore legs. The oppoſite term to embracing a volt, is beating the duſt, which is putting his fore-feet near the place from whence he lifted them.

Embracing the ground is uſed in the ſame ſenſe with embracing the volt. A horſe cannot take in too much ground provided his croupe does not throw out; that is, does not go out of the volt. See Beat.

EMBRACEOR, in *Law*, a perſon who, when a matter is in trial between party and party, comes to the bar with one of the parties (having received ſome reward ſo to do), and ſpeaks in the cauſe, or privately labours the jury, or ſtands there to overlook, awe, or put them in fear; or, who makes any attempt to influence a jury corruptly to one ſide by promiſes, perſuaſions, intreaties, money, entertainments, and the like. (1 Hawk. P. C. 259.) The puniſhment for the perſon embracing is by fine and impriſonment; and for the juror ſo embraced, if it be by taking money, the puniſhment is (by divers ſtatutes of the reign of Edward III.) perpetual infamy, impriſonment for a year, and forfeiture of the tenfold value.

EMBACERY, the act or offence of embraceors. See Embraceor.

EMBRASURE, in *Architecture*, an enlargement of the gap or aperture of a door, or window, within-ſide the wall. See Door.

Its uſe is to give the greater play, for the opening of the door, wicket, caſement, &c. or to take in the more light.

The embraſure coming ſloping inwards, makes the inner angles obtuſe. When the wall is very thick, they ſometimes make embraſures on the outſide.

Embrasure, in *Fortification*, is an opening made through the upper part of the defences, called the *parapet*, for the purpoſe of pointing the cannon, ſo as to be as little as poſſible expoſed to the fire of the enemy. The embraſure muſt vary in dimenſions with the ſeveral ſizes, or, as they are technically termed, the "natures" of the cannon to be employed in them reſpectively. It is, however, generally found, that about 2½ diameters of the muzzle of the cannon intended to be mounted give ſpace enough for traverſing, and at the ſame time afford but little opening for the ſhot from oppoſing batteries. The embraſure muſt be cut down in that proportion which may ſuit the height of the carriages on which the cannon may be mounted: thus, for all under 24 pounders, the height, between the front of the platform, and the creſt, *i. e.* the interior, or higheſt part of the ſlope, over which the cannon is levelled, ought not to exceed 28 inches, unleſs the trucks on which the carriages run are unuſually high; for all cannon of 24 pounds calibre, and upward, the ſpace above deſcribed, and which is called the *genouillere*, ought to be from 34 to 40 inches. The beſt rule is, to allow eight inches between the creſt of the ſlope and the under part of the cannon, when horizontally laid, thereby to command freedom of action, even when the depreſſion of the line of fire may be conſiderable: were this not attended to, the cannon might, at ſuch times, be levelled after each diſcharge, before it could be run up to the *genouillere*; whereby conſiderable delay would be created. The ſlope, by which we mean that part under the muzzle of the cannon, is ordinarily made with a deſcent of about ten or twelve degrees from the creſt outwards, to allow of depreſſion, ſo as to fire either into the ditch, or over the glacis; this ſlope muſt neceſſarily vary according to the ſituation, and intention of the battery. Thus, in ſome ſituations it is found neceſſary even to invert the ſlope, the cannon being always pointed above the horizon: this occaſionally happens in erecting batteries while beſieging a place, where it would be both uſeleſs and diſadvantageous to cut the embraſures any lower than the loweſt direction to which the cannon ſhould be pointed. On the other hand, we ſometimes ſee the ſlopes made at full forty degrees of depreſſion, in conſequence of the battery being intended to command ſome work, of approach, far below its own level. But, as before obſerved, when works are conſtructed upon an ordinary *defilement*, (or branching out,) originating from a level at the exterior of the *glacis*, and proceeding without any increaſe of elevation to the centre of the place, then from 10 to 12 degrees of depreſſion in the ſlope will be fully adequate to all the purpoſes of depreſſion of the cannon. The expanſion of an embraſure, that is, its becoming wider exteriorly, than it is interiorly, muſt depend on circumſtances; but we generally find their ſides to diverge at an angle of about 12 or 15 degrees from a line paſſing through the centre of the ſlope, in a direction with the chace of the cannon when brought up ſquare to the *genouillere*. It ſhould, perhaps, ſeem proper to make the embraſure ſpread as widely as poſſible, for the purpoſe of including a greater extent of direction; but were ſuch to be practiſed, the *merlon*, *i. e.* the body of parapet left between any two embraſures, would be ſo conſiderably diminiſhed as to afford little protection from the enemy's ſhot, which would, at the ſame time, gain admiſſion, obliquely, into the battery, and diſmount the cannon by a plunging fire. On the other hand, it is abſolutely neceſſary to give ſuch an expanſion as may not only allow the reaſonable traverſing of the cannon, thereby to cover a greater extent of the approaches, but to prevent the *merlons* from being deſtroyed by the fire of their own cannon, of which the exploſion would ſpeedily bring down the revetements, whether of maſonry or of turf, unleſs ample ſpace were allowed for the concuſſion of the air created by the diſcharge to be ſufficiently weakened. We have heard of defences that were deſtroyed rather by the want of this conſideration, than from the enemy's fire. Where the *merlons* are of ſolid maſonry, and conſequently the thickneſs of the parapet inconſiderable, when compared with that attendant upon *merlons* made of ſoil, there may be allowed rather more contraction than in the latter caſe, becauſe the exploſion is not confined for ſuch a diſtance. Few caſes, however, can occur, in which the divergence of the ſides can come under ten, or exceed fifteen degrees. Where it is not adviſeable to keep all the intended embraſures open, or where deception is an object, they are either left unfiniſhed, the parapet being left entire, or their fronts are filled up with the ſame materials as the front of the parapet. The former is common in ſituations where the ſoil is looſe, and the difficulty of ſuſtaining the merlons conſiderable. When embraſures are cut through ſuch parapets, their ſides muſt be ſuſtained by *faſcines*, as in the caſe of field batteries, and approaches during a ſiege. The latter deſcription, *i.e.* the concealed embraſures, form what is called a maſked battery, which generally opens by ſurpriſe; the firſt diſcharge generally ſerving to clear away the ſlight work built up for the purpoſe of concealing the ſituations of the cannon. Where it is abſolutely neceſſary that cannon ſhould be allowed to traverſe freely in various directions, ſuch, for inſtance, as ſea-lines, where every gun ſhould be made to follow a ſhip paſſing with a rapid tide, and likewiſe in block-houſes mounting heavy ordnance on their roofs, no embraſures ſhould be made; but the cannon ſhould be mounted on carriages traverſing on pivots, and elevated above the body of the ramparts, which may nevertheleſs be made high enough to cover the defenders very completely. Cannon mounted in this manner command a great range of direction, and, though not ſo well ſecured from being diſmounted as when placed in embraſures, are pre-eminently ſerviceable in ſome ſituations. Batteries of this deſcription are called *barbet batteries*, and ſhould, with little exception, be invariably preferred, wherever they are not liable to be oppoſed by cannon, or where the force to be acted upon is expected to paſs with velocity, without being able to take a ſettled aim at the *barbet*. Mortar batteries have no embraſures, they requiring only a given line of direction, aided by due elevation, to effect their object; and, as both may be given without ſeeing it, the parapets of ſuch batteries are left entire. What are called embraſures on board bomb-ketches, are nothing more than temporary openings made by unſhipping hatches, and by fitting ſtout planks at the ſides to confine the ſparks from ſpreading within the veſſel. In caſemates, eſpecially thoſe in the *curtain*, &c. the embraſures are made like the portholes in a ſhip; that is, nearly ſquare, and allowing the muzzles of the cannon to paſs completely through.

EMBREGMA, an embrocation. The term is derived from εμβρεχω, *to make wet.*

EMBROCATION, or rather Embrochation, *Embrocha*, Εμβροχη, formed from βρεχω, *irrigo*, *I ſprinkle*, or *moiſten*, in *Pharmacy*, denotes the application of remedies, as oils, ſpirits, decoctions, and other liquids, by ſprinkling, or even rubbing them on the part affected: this is alſo called irrigation.

Embrocations are only a kind of lotions; they are uſed to remove obſtructions, and to relieve pains, numbneſs, and palſies. The pumping uſed in natural baths is properly an embrocation.

Embrocation, *gall.* See Gall.

EMBROIDERY, the enriching of a cloth, ſtuff, or muſlin, by working diverſe figures thereon with the needle, and thread of gold or ſilver.

The word embroidery is derived from the French *broiderie*, of *broider*, *to embroider;* which ſome deduce, by tranſpoſition, from *bordeur*, becauſe they formerly embroidered only the borders of ſtuffs, whence the Latins alſo call the embroiderers *limbularii*. Du-Cange obſerves, that they anciently wrote *aurobruſtus* for embroidered with gold, or *bruſtus brudatus*, and *brodatus*; whence *broderie*.

That done with ſilk, flax, or the like, is not now called embroidery; though anciently, and properly, the word denoted all kind of figuring or flouriſhing.

The chief uſe of embroidery is in church veſtments, cloaths, houſings, guidons, ſtandards, &c. The invention of embroidery is attributed to the Phrygians; whence the Latins call embroidered garments "veſtes Phrygioniæ," and embroiderers *Phrygiones*. In the "Menæchmi" of Plautus, (act ii. ſcene 3), a young woman, deſirous of ſending her mantle to be embroidered, ſays: "Pallam illam ad phrygionem ut deferas, ut reconcinnatur atque ut opera addantur, quæ volo." The Greeks ſeem to have uſed the words κεντειν and καταστιζειν, as we uſe the word embroider.

The embroidery of ſtuffs is performed in a kind of loom; that of muſlin is done by ſtretching it on a pattern already deſigned; the former kind is the moſt eaſy, but the latter admits of the greateſt richneſs and variety. The thinneſt muſlins are the beſt for this purpoſe; and they are embroidered to great perfection in Saxony.

There are diverſe kinds of embroidery; as *embroidery on both ſides*, that which appears on both ſides. *Guimped embroidery*, performed either in gold or ſilver. In this work, a ſketch is firſt made on the cloth, then they put on a cut vellum, and afterwards ſew on the gold and ſilver with ſilk thread, interſperſing ſilver and gold cord, tinſel, and ſpangles. *Embroidery on the ſtamp*, where the figures are very high and prominent, being ſupported on wool, cotton, hair, &c. *Low and plain embroidery*, where the figures are low and flat, and without any enrichment between them. It is probable that the covering of the ſword of Goliath, which was laid up in the tabernacle as a conſecrated memorial of the victory gained by David over that vain-glorious idolater, or the wrapper that enveloped it, was ſome beautiful piece of embroidered work. (1 Sam. xxi. 9.) By ſtatute 22 Geo. II. c. 36. no foreign embroidery, or gold or ſilver brocade, ſhall be imported, upon pain of being forfeited and burnt, and penalty of 100*l.* for each piece. No perſon ſhall ſell or expoſe to ſale any foreign embroidery, gold or ſilver thread, lace, fringe, brocade, or make up the ſame into any garment, upon pain of having it forfeited and burnt, and penalty of 100*l.* All ſuch embroidery, &c. found, may be ſeized and burnt, and the mercer, &c. in whoſe cuſtody it was found ſhall forfeit 100*l.*

EMBRUN, or Ambrun, in *Geography*, a town of France, in the department of the Upper Alps; chief place of a diſtrict of the ſame name, ſituated upon a high rock on the right ſhore of the river Durance, 66 miles S.W. of Grenoble, and 480 miles S. by E. of Paris, is chiefly remarkable for its cathedral, and has a population of 3138 individuals. The canton contains 8 communes and 9667 inhabitants, on a territorial extent of 285 kiliometres.

As chief place of a diſtrict Embrun has a ſub-prefect, two courts of juſtice, and a regiſter office. The whole diſtrict is extremely mountainous, but the vallies and the declivities of the mountains are uncommonly fertile. It contains five cantons, 36 communes, and 26,968 inhabitants, on a territorial extent of 1472½ kiliometres.

EMBRYO, or Embryon, in *Anatomy* and *Phyſiology*, is the child, with its coverings, as contained in the uterus previouſly to the time of birth. It is ſuppoſed at firſt to be in an imperfect ſtate, but to contain rudiments of all the parts, which, when fully developed, make up a perfect animal. The term is derived from the Greek word εμβρυον, which has the ſame ſignification, and is formed from εν, *in*, and ϐρυω, *I ſhoot out;* conveying a notion, that the living germ buds forth and expands in the uterus of the mother, as a ſeed is developed in the earth. The term embryo is employed, in its moſt ſtrict acceptation, during the firſt ſix weeks only after conception, but it is often uſed more generally during the whole time of utero geſtation. The young animal, after the firſt ſix weeks, is called a *fœtus;* but we uſe this word alſo to denote the ſame object as ſoon as it can be diſtinctly perceived. By the *ovum*, we underſtand the fœtus, together with its ſurrounding membranes; but that term is ſometimes applied to the latter only, in contradiſtinction to the former. We ſhall conſider, under the preſent article, the progreſs of the uterine contents, until the time of utero-geſtation is completed; the changes, which they paſs through, in the different ſtages of this period; the peculiarities of ſtructure belonging to the fœtus; and the mode of its nutrition and exiſtence.

A ſketch of the progreſs of the germ, after impregnation, from the ovarium into the uterus, and of its developement in the latter cavity, will be found in the article CONCEPTION; a more detailed hiſtory of the anatomy of the ovary and uterus, together with a ſtatement of all the facts that can be aſcertained concerning the mode of impregnation, and its immediate conſequences, will be contained under the head of GENERATION.

When the germ is detached from the ovarium, the mode of its exiſtence differs in the different claſſes of the animal kingdom. In the greateſt number of inſtances it is accompanied by an organized maſs, to which it adheres by means of veſſels, and the abſorption of which is ſufficient to nouriſh and develope it, until it is brought forth into the world. It requires no ſupply therefore from the body of the mother; and is even ſeparated from her by more or leſs numerous and ſolid coverings. The germ, together with the nutritious ſubſtance, and the common envelopes, conſtitute an *egg*, and the animals which propagate their ſpecies in this way, are called *oviparous*. In many of theſe, the germ contained in the egg is not developed and hatched, until the egg has quitted the body of the mother, or has been *laid;* in which caſe fecundation may be performed afterwards, as in many fiſhes, or external heat only may be required, as in the incubation of birds: or, laſtly, the natural temperature of the climate may ſuffice, as in reptiles and inſects. All theſe are *oviparous* animals, properly ſo called. In ſome others, the egg, after having been fecundated, and detached from the ovary, remains in the mother's body, until the young one is developed and hatched, as in the viper, and in ſeveral fiſhes: ſuch are falſely viviparous, or *ovo-viviparous* animals. Mammalia only are truly *viviparous;* their germ is provided with no ſupply of aliment, but derives the materials of its growth from the juices of the mother. For this purpoſe it is attached to the internal ſurface of the uterus, and occaſionally, by accident, to ſome other part, by a kind of root; by an infinite ramification of blood-veſſels, conſtituting the *placenta*. Inſtead, therefore, of being ſeparated by its coverings from the body of the mother, theſe are the medium of a moſt intimate connection between them, eſſentially neceſſary to the life of the germ. Through them there is a conſtant influx of nutritious juices until the embryo is completely developed. At that time the membranes are torn, and the young animal comes into the world, capable of enjoying an independent organic exiſtence, and free from all external covering. The very rare occurrence, of the child being born with its membranes entire, cannot be regarded as an exception to this aſſertion: Wriſberg only ſaw it three times in 2000 births; (ſee his Obſervat. de Structurâ ovi, p. 76.) and it is probably ſtill leſs common on the average. In the mammalia then there is no *egg*, in the ſenſe already explained: the membranes of their *ovum* being an intimate connection between the mother and the germ, by which the former ſupplies the latter with nouriſhment; while the *egg* is entirely detached, and contains, with the germ, the nouriſhment neceſſary for its growth. Hence we ſee that the old and much-conteſted maxim of "omnia ab ovo," cannot be received without great limitation, and is more likely to perplex, by confounding together things eſſentially different, than to impart any additional light to a ſubject already very obſcure.

The following parts, which are of courſe contained in the cavity of the pregnant uterus, make up the human ovum; *viz.* the *placenta, membranes, navel-ſtring, liquor amnii,* and *fœtus*. The three firſt are called alſo the ſecundines or after-birth; as they are expelled, in the act of parturition, after the child. The placenta and membranes every where line the cavity of the uterus, and the former muſt undoubtedly have ſome communication with the veſſels of the mother, although anatomiſts have not yet ſucceeded in demonſtrating the preciſe mode of that connection. In the membranous bag formed by the ſecundines, there is found, beſides the fœtus, a greater or ſmaller quantity of clear fluid, called the liquor amnii. The umbilical chord contains blood-veſſels, by which the circulating organs of the fœtus communicate with the arteries and veins of the placenta.

The ſecundines are all more or leſs gelatinous and tranſparent, and contain no manifeſt fibrous ſtructure. Being deſtroyed after every pregnancy, their exiſtence is temporary; and their organization correſponds to this limited term of duration. They never contain any fat, either in the ſound, or in the morbid ſtate of parts, at any period of utero-geſtation, however the mother or child may be circumſtanced in this reſpect.

The cavity of the uterus, examined immediately after conception, exhibits nothing which can be regarded as the fruits of that proceſs. In a few days, we perceive a tranſparent membranous veſicle, filled with a gelatinous liquor, but offering no appearance of organization or life. Some writers have aſſerted that ova may be found in the uterus of the human ſubject, or of animals, immediately after conception; and have even publiſhed delineations of them in the firſt days of pregnancy. Such ſtatements deſerve no credit. Thoſe modern phyſiologiſts, in whom we can place the greateſt confidence, have found, during the firſt ſeventeen days, nothing but a fluid like white of egg, in which there was no trace of any more conſiſtent body. Mr. Cruikſhank, however, has met with ova in the tubes and uteri of rabbits, at a much earlier period. He found them in the former ſituation on the third day after coition: they were mere points, but the diſtinction of the chorion and amnios could be diſcerned by the aid of magnifying powers. The fœtus was rendered viſible on the eighth day, by pouring vinegar on the ovum. We may regard all obſervations in which an ovum is ſaid to have been diſcovered in the human ſubject, earlier than the twentieth day, as extremely ſuſpicious: indeed, we know of no inſtance, in which it has been obſerved, before this time, by any perſon whoſe teſtimony has ſufficient authority. A round little body is gradually developed in the cavity of the uterus, and may be recognized at the end of the third week. This is the covering of the future, but not yet diſcernible fœtus. The ſurface of ſuch an ovum is probably flocculent from the firſt; this at leaſt is the caſe in the ſmalleſt hitherto delineated, and in well preſerved ſpecimens of very ſmall and early abortions. The flocculi are very fine vaſcular ramifications, connecting the ovum to the decidua, which reſembles in appearance a layer of coagulable lymph produced by inflammation. The reſemblance of theſe villi to the roots of a plant, the mode of their inſertion in the decidua, and the analogy of their function, in draining from the uterus and conveying to the child, the materials of its ſupport, to the office which roots perform, in extracting nouriſhment from the ſoil, has led almoſt every writer to compare the rudiment of the future animal to a ſeed, and to conſider its connection with the mother's body as ſimilar to that between a plant and the earth. The vaſcular proceſſes are ſmall in very young ova, but enlarge afterwards rapidly till the ſecond month: they gradually diſappear from two-thirds of the ſurface of the ovum, and are collected together on the remainder, to be united into a maſs, and form the placenta.

It has not been hitherto determined at what period the ovum becomes connected to the uterus; indeed it is ſo ſmall, at its firſt arrival in the cavity, that the inveſtigation is difficult. Cruikſhank ſays, that the ovum increaſes in the rabbit, to one hundred times its original ſize, before it becomes fixed to the uterus. The ſize of the ovum, at different periods of pregnancy, cannot be determined with much accuracy, becauſe many abortions are not well formed, and their exact age cannot be well aſcertained. Hence different writers contradict each other conſiderably in this point. Within the firſt month it is not larger than a hazel nut; in the ſecond and third it may equal a pigeon's or hen's egg. At the latter period its developement is complete, and the future changes are chiefly in ſize. It increaſes in proportion to the augmentation of the uterus.

Particular deſcription of the component parts of the ovum.— The membranous covering including the fœtus, within the uterus, conſiſts of ſeveral diſtinct parts, which admit eaſily of artificial ſeparation. The number of theſe has been very variouſly repreſented. The older anatomiſts only deſcribe two; *viz.*, the chorion and amnios; and divide the former into two laminæ. Moſt moderns deſcribe three coverings, adding the decidua of Hunter to the two former. Haller mentions four;—the membrana exterior ovi, chorion, membrana media, and amnios. Blumenbach's diviſion into the proper, and adventitious coverings is a good one: the latter are the chorion and amnios; the former, the decidua, which covers the ovum and lines the uterus.

The *decidua*, or *membrana caduca*, is the medium of connection between the embryo and the mother. In its appearance, as well as in its mode of formation, it reſembles the lamina of coagulating lymph, which is formed by inflamed ſurfaces. Both membranes are of a yellowiſh white colour; both are tender, pulpy, and vaſcular. The lamina of lymph is formed by an inflamed membrane; the uterus, before the appearance of the decidua, becomes much more vaſcular, and is probably in a ſtate of increaſed action analogous to inflammation. The developement of this membrane is probably anterior to the arrival of the germ in the uterus, and may be regarded as a meaſure of preparation for its reception. It is not neceſſary for the formation of the decidua, that the ovum ſhould reach the uterus. For when it grows in the ovarium, or in the Fallopian tube, the decidua is formed in the uterus, and that organ is conſiderably enlarged; ſo that it undergoes, to a certain degree, changes exactly ſimilar to thoſe which take place in natural pregnancy. It lines the whole internal ſurface of the uterus, being perforated at the Fallopian tubes, and cervix uteri. Numerous ſmall arteries and veins, often ſeen containing red blood, ramify from its outer ſurface inwards through its ſubſtance, and are derived from the veſſels of the uterus. It is very thin, and has no perceptible veſſels near the cervix uteri; but grows thicker and more vaſcular towards the placenta, at the very edge of which it acquires a conſiderable thickneſs, and ſplitting into two ſtrata, is continued over both ſurfaces of the placenta, but eſpecially the inner ſmooth ſurface, blending itſelf there inſeparably with the umbilical portion of the placenta. The layer of the decidua, which lies between the chorion and placenta, is in one caſe much thicker than in another. It ſometimes forms a ſmooth, tender, opaque membrane; but is more frequently reticulated, eſpecially towards the edge of the placenta, looking ſomewhat like lace. Occaſionally there are portions of it a good deal thicker than the reſt; which, ſhining through the tranſparent chorion, bear ſome reſemblance to pieces of fat. This layer is generally thicker than that which adheres to the rough, external, lobulated ſurface of the placenta. It communicates with that other, by means of the proceſſes of the decidua, which paſs between the lobules of the placenta, and along the external ſurface of the umbilical veſſels.

We have already obſerved, that the decidua adheres cloſely, on its external ſurface, to the uterus, and that this adheſion is effected by means of blood-veſſels paſſing to the former from the latter. By its means the whole external ſurface of the ovum grows to the uterus. Its internal ſurface is very cloſely attached to the chorion, ſo that their ſeparation is difficult in recent ſecundines. Gentle putrefaction makes them part eaſily; and we obſerve, on the ſeparation, numerous white ſlender threads, emerging from the ſubſtance of the chorion, and ramifying into ſmaller filaments upon the decidua. Theſe appear like veſſels by the aid of a magnifying glaſs.

As this membrane is an adventitious production of the internal ſurface of the uterus, formed for the temporary purpoſe of a connecting medium between the mother and the child; its office ceaſes as ſoon as the fœtus has quitted its original ſituation; and it is conſequently ſhed whenever a woman bears a child, or ſuffers a miſcarriage. Hence its names of *decidua* and *caduca*. As it may be partially ſeparated into two ſtrata, one of theſe is left on the uterus after delivery, and afterwards diſſolves, and comes away with the lochia. Frequently a thicker ſtratum ſeparates from the uterus in one part, and a thinner in another. The adheſion of the decidua to the uterus and chorion is ſtronger than that of the two layers of the membrane to each other; and hence, probably, we may explain the circumſtance of a ſtratum being left upon the uterus after parturition. The beſt method of ſeeing the decidua after labour, is to waſh the ſecundines well in warm water, to remove the looſe coagulated blood, and then put them into cold water, that the blood, which remains in the veſſels, may congeal. The decidua will then be very diſtinguiſhable by its yellowiſh appearance and pulpy conſiſtence; and numerous veſſels may be clearly diſcerned in its ſubſtance. The number and ſize of the veſſels, paſſing from the uterus to the decidua, ſufficiently account for the bleeding which always takes place on the ſeparation. Theſe veſſels are repreſented as filled with blood in Hunter's 29th plate, fig. 4: and in their injected ſtate in ſeveral other figures of the ſame work; *viz.* the arteries in fig. 3, tab. 24; the veins in tab. 24, fig. 4: and both kinds of veſſels coming from the uterus, in tab. 31. The ſecond fig. of tab. 29. of the ſame work, exhibits the reticulated lace-like appearance of the membrane, when viewed with magnifying powers: in this reſpect it much reſembles the adventitious productions of coagulating lymph.

The preceding deſcription applies to the decidua, as it is found in ova of ſeven, eight, or nine months. The membrane is very different in the earlier periods; and as the deſcriptions of anatomiſts have been derived chiefly from abortions, in which more or leſs of the decidua may come away with the ovum, and as the appearance of the membrane differs very much in the different periods, the accounts of it are very perplexed, and difficult to underſtand. The thickneſs of the membrane is in an inverſe ratio to the age of the embryo. In an early ſtate, too, its external ſurface is covered with numerous looſe and floating flocculi, by which it adheres to the ſurface of the uterus; theſe are not ſeen at more advanced periods: they are excellently repreſented in an abortion of the ſeventh week, in two beautiful figures, forming the vignette of the title page of Soemmerring's Icones Embryonum Humanorum: alſo in Hunter, figs. 1, and 2. pl. 33.

From the time that the ovum has acquired ſome ſize, until about the fourth month, the decidua not only lines the whole cavity of the uterus, but alſo gives another covering to that part of the chorion, which is not occupied by the placenta. This ſecond inveſtment is continuous with the former at the edge of the placenta; and, as it appears at this part as if reflected from the exterior layer over the ovum, Dr. Hunter, to whom we are indebted for the moſt accurate obſervations on the whole ſubject, called it *decidua reflexa;* the addition of Hunteri is often made by foreign anatomiſts. He compares, in the explanation of pl. 33, fig. 1, the reflection of the decidua over the ovum, to that of the pericardium over the heart; and the compariſon might be correct, if the exterior portion of the pericardium covered the whole of the heart, as the outer layer of decidua does the whole ovum. According, then, to the preceding deſcription, we may diſtinguiſh three portions of decidua, all, however, completely connected together; 1ſt. The exterior portion, covering the whole ovum, and lining the whole uterus, excepting the apertures correſponding to the Fallopian tubes and cervix; *decidua uteri, d. vera, membrana ovi exterior* of Haller, membrana caduca *craſſa* of Mayer (Beſchreib. des menſchlichen Körpers, v. 5. ſ. 272.) becauſe it is thicker than the reflected portion, firſt membrane of the ovum of Mekel, decidua externa of Sandifort, and external lamella of the Hunterian decidua of ſome authors. 2dly. A production over the concave ſurface of the placenta. 3dly. D. *reflexa*, covering the chorion, and continuous at the margin of the placenta, with the D. uteri. This is Blumenbach's acquired membrane, Mekel's ſecond membrane, villoſa membrana placentæ, involucrum membranaceum of Albinus, membrana filamentoſa of Wriſberg and Roderer, chorion of Haller, chorion fungoſum, flocculentum, &c., ſpongy chorion, reflected vaſcular membrane, &c. Denman calls it connecting membrane, and Baillie decidua chorii. A cavity muſt neceſſarily be intercepted between this and the d. uteri. The diſtinction of theſe two parts, and their relative poſition, are beſt ſeen in the plates of Hunter; as in fig. 1, of tab. 28: alſo in a perpendicular ſection of the uterus, containing an ovum of three months, repreſented in tab. 32, where the letters *k*, *l*, *m*, *n*, *o*, repreſent the two deciduæ, the angle of reflection, and the cavity left between them. The ſame facts are alſo repreſented in two abortions, figs. 1, 2, 3, and 4, of tab. 33. The d. reflexa covers the ſhaggy veſſels of the chorion, which ſeem to be implanted in it. In proportion as pregnancy advances, it becomes gradually thinner and thinner, ſo that at the fourth month it forms an extremely fine layer covering the chorion. It comes at the ſame time into more cloſe contact with the d. uteri, and, at length, the two adhere together. Yet the membrane diminiſhes in thickneſs, and continues to decreaſe until parturition. How it comes to paſs, that the decidua ſhould envelope the ovum in the way already deſcribed, is mere matter of ſuppoſition, and does not admit of being ſhewn by direct demonſtration. In two examinations, mentioned by Dr. Baillie as having been performed with great care at an early period of pregnancy, the decidua was already formed, but no ovum could be diſcovered.

In the 18th fig. of his work already quoted, Soemmerring has given an excellent view of the external ſurface of an ovum of five months. It appears on cloſe inſpection covered with fine and thinly ſcattered flocculi, which are the moſt numerous and long in the ſituation of the placenta. The firſt, or external coat, (the decidua,) is continued into the placenta, or the placenta is extenuated into this membrane, in ſuch a way, that we might, with equal propriety, either regard the placenta as the thickeſt portion of the decidua, or the decidua as an extenuated production from the placenta. The decidua grows gradually thinner as we recede from the placenta, ſo that its thinneſt portion is preciſely oppoſite to the placenta.

The *chorion* is that covering of the ovum which is placed next in order to the decidua. It is the firſt proper membrane of Blumenbach, the third membrame of Mekel, and the ſecond of many anatomiſts; the membrana media of Haller, chorion pellucidum or læve.

It is a firm and ſtrong membrane, forming a complete bag, which includes the amnios and child. It adheres firmly to the concave ſurface of the placenta, and in that ſituation is thicker, and covers the great diviſions of the umbilical veſſels; being cloſely attached to the amnios at the inſertion of the umbilical chord. At firſt it is nearly tranſparent, and tender in its texture: as the ovum increaſes, it becomes more opaque, ſtronger, and of a yellowiſh colour. We have mentioned already how its external ſurface adheres to the decidua, and the threads connecting them together, which ſeem to be veſſels. Theſe are the only veſſels which the membrane poſſeſſes.

The external ſurface of the chorion is covered completely with flocculi in the firſt month of pregnancy. A great abundance of thin tender threads of different thickneſs ariſe from it. Theſe divide and ſubdivide in a very minute manner, and the neighbouring ramifications join each other. They are extremely ſmall on very young ova; but they cover the whole ſurface at the end of the firſt, and in the ſecond month. They diſappear from ſome parts in the third month; and collect cloſer together towards the upper part of the ovum, in order to form the placenta.

The decidua reflexa, covering this external ſurface of the chorion, unites the flocculi together; which penetrate it, and are implanted in the decidua uteri. Many erroneous names and repreſentations have ariſen from this ſtructure, becauſe the proceſſes of the chorion have been regarded as belonging to the d. reflexa; and hence many of the names applied to that membrane have ariſen.

In the fourth, fifth, and ſixth months the chorion is ſmooth on the greateſt part of its external ſurface. The d. reflexa, which is now thin and ſcarcely recognizable, is cloſe upon it. When the placenta is formed, the external ſurface of the chorion is firmly attached to its concavity.

The internal ſurface of the chorion is ſmooth, and united to the amnios: In the firſt month there is a conſiderable interval between the two membranes, filled with a clear aqueous fluid, probably produced by the veſſels of the chorion: this ſpace is ſoon diminiſhed; the amnios growing faſter than the chorion, the two membranes ſoon come in contact. In the third month they lie near together, and are looſely connected by a tender gelatinous medium.

Twins have a double chorion, as well as amnios; but are covered by a common decidua reflexa.

Amnios; the ſecond proper membrane of Blumenbach; and fourth membrane of Haller and Mekel; is found univerſally in animals. In man it forms an oval bag, including a certain portion of fluid, and the fœtus. It is a thin tranſparent membrane, of tolerably firm conſiſtence. Its external ſurface is connected, in the way already deſcribed, with the chorion, from which it is eaſily ſeparable. It lines the concave ſurface of the placenta, and terminates, apparently, by a cloſe adheſion at the inſertion of the navel-ſtring, where the chorion alſo ſeems to end. The gelatinous ſubſtance connecting the two membranes adheres more cloſely to the amnios than to the chorion, and hence the former membrane has a rough appearance, when ſeparated. The internal ſurface is every where perfectly ſmooth. In birds and quadrupeds it poſſeſſes manifeſt veſſels; but none in the human ſubject.

The allantois, which was formerly enumerated among the membranes of the human ovum, is now known to be peculiar to quadrupeds.

There is, however, a ſmall membranous bag, named *veſicula umbilicalis*, found in the early months of pregnancy between the amnios and chorion. This poſſeſſes an elliptical figure, and contains a clear fluid. It contracts into a thin and round thread, which runs along the navel-ſtring, and divides into two at the inſertion of the umbilical chord in the child's body. They are afterwards loſt upon the viſcera. This veſicula can only be ſeen until the third month, and in very freſh abortions; for it is ſo delicate that it decays very quickly; and it is extremely difficult to trace the thread from it through the umbilical chord. Its ſize is in an inverſe ratio to the age of the embryo.

Liquor amnii is the name given to the fluid which fills the cavity of that membrane. This is perceivable as ſoon as the ovum can be diſcerned; it diſtends the membranes, and preſerves their rounded form. Its quantity is the largeſt, in proportion to the ſize of the embryo, in the firſt month of pregnancy; ſo that in the firſt and ſecond it conſiderably exceeds the weight of the fœtus, which muſt conſequently be looſely ſuſpended in the fluid. The fœtus weighs more in the third month than the liquor amnii; and, as it touches the membranes in the fifth, the proportional quantity of the water has very greatly decreaſed; ſo that it merely filled up the intervals cauſed by the inequalities of the child's body. Stein, an experienced German writer, ſtates that the weight of the fœtus and the amniotic fluid ſhould be equal about the middle of pregnancy; and that it muſt be regarded as an unnatural appearance, if the latter exceeds the former in the ſixth month. It continues afterwards conſtantly decreaſing relatively to the increaſe of the child. The quantity varies greatly in different ſubjects; from one to two pounds is the ordinary proportion at the period of nine months; but it may be much more or leſs. It is a clear yellowiſh fluid; but ſometimes differently coloured and obſcure. In its pure ſtate it poſſeſſes no ſmell, and a mild ſaltiſh taſte. Heat and alcohol coagulate it in the recent ſtate; but the chief bulk of it is aqueous. The ſources of the ſecretion are unknown. The abſurd opinions, by which it has been ſuppoſed to proceed from the ſkin or various other parts of the fœtus, are ſufficiently refuted by the fact of its exiſtence when there is no fœtus. The amnios poſſeſſes no apparent veſſels. For an account of the chemical properties of this fluid, ſee the article AMNIOS.

The old opinion of the uſe of the amniotic fluid in nouriſhing the fœtus cannot be ſuſtained; for deglutition could not be performed without the preſence of air; many fœtuſes are born with the mouth cloſely ſhut, and others have grown to the full ſize without any mouth at all. The great uſe of the fluid ſeems to be that of protecting the fœtus from external violence; and hence we find it moſt copious when the child is youngeſt and moſt delicate in texture, to prevent its different parts from adhering together, or to the ſurrounding membranes. The buſineſs of parturition, as far at leaſt as the dilatation of the os uteri is concerned, is alſo facilitated by the liquor amnii.

The *umbilical chord*, *funis* or *funiculus umbilicalis*, or navel-ſtring, made up of three large veſſels twiſted together, united by more or leſs gelatinous ſubſtance, and conſtituting, in conſequence of certain convolutions of the veſſels, an irregular rope, rather leſs in general than the ſize of the little finger, is fixed at one end to the child's navel, and at the other to the placenta. This being the organ of communication, through which the materials of growth and nouriſhment are derived to the fœtus from the mother, conſtitutes a moſt eſſential part of the ſecundines, and can never be deficient. It paſſes through the liquor amnii, from the child to the reſt of the ſecundines; is commonly about two feet long, but may be no more than one foot, or on the contrary exceed four feet. Wriſberg once ſaw it only ſeven inches long; and it was neceſſary to cut it in the courſe of the delivery. Its moſt frequent length is between 18 and 22 inches. The younger the fœtus, the ſhorter is the chord proportionally. It is alſo thicker relatively to the ſize of the fœtus, as that is younger. It is uſually turned round ſome part of the child's body; very commonly round the neck, which it has been ſeen to encircle four times and a half.

From the important function performed by the navel-ſtring, we ſhall expect to find it as ſoon as the embryo itſelf is perceptible; and conſequently it is ſeen as ſoon as the fœtus itſelf is viſible.

The veſſels of the chord are two umbilical arteries, and one umbilical vein. The two arteries are of equal ſize, and poſſeſs ſtrong coats, ſo that their ſection preſents a circular area. In rare inſtances there is only one. The umbilical arteries are a continuation of the internal iliacs; which, inſtead of deſcending into the pelvis, aſcend along the ſide of the bladder to the umbilicus. When there is only one umbilical artery, the internal iliac of one ſide only is reflected along the bladder. The internal iliac, which in the adult is no larger, but rather ſmaller than the external, is conſiderably the largeſt of the two in the fœtus. It paſſes obliquely from the ſide of the pelvis to that of the bladder, and takes the name of umbilical or hypogaſtric; croſſing the ureter in ſuch a manner that that tube lies internally, and the artery externally. It aſcends along the ſide to the fundus of the bladder, and proceeds over the ſurface of the peritoneum, to the umbilicus. Theſe veſſels make very numerous convolutions and turnings which differ conſiderably in different ſubjects: and hence they are much longer than the length of the chord. In the ſituation of theſe turns, the diameter of the veſſels will appear contracted, and theſe contractions are the *quaſi-valvulæ* of Hoboken.

The third veſſel of the chord is the umbilical vein, which ariſes from the placenta, forms numerous convolutions, in company with the arteries, and enters the child's body at the umbilicus. Paſſing over the ſurface of the peritoneum, it arrives at the ſuſpenſory ligament of the liver; deſcends along its anterior margin to the foſſa, dividing the two lobes; and there enters the ſubſtance of the liver. It diſtributes ſeveral branches to this viſcus, particularly to its left lobe, and ends by an anaſtomoſis of its trunk, with the left branch of the vena portarum. From the veſſel formed by this union a ſmall canal, about three quarters of an inch in length, is continued into the inferior vena cava, under the name of *ductus venoſus*.

The umbilical vein is much larger than the artery, and its ſides collapſe when divided. It is ſaid that two veins have been ſeen; but Dr. Hunter never met with a caſe; quadrupeds have two. The umbilical veſſels give off no viſible branches till they come to the placenta; then the two arteries anaſtomoſe, commonly by a croſs canal, nearly of the ſize of one of the arteries.

“ There is a great variety,” ſays Dr. Hunter, “ in the twiſting of the veſſels of the navel-ſtring. Sometimes they are uniformly and cloſely twiſted like a rope, in their whole courſe; and ſometimes they run almoſt ſtraight and parallel, eſpecially in that part of the ſtring which is towards the placenta; for near the fœtus it is almoſt always more or leſs twiſted. In ſome navel-ſtrings there is a great irregularity, from ſolitary turnings of particular veſſels, commonly called knots, as we ſee in twiſting a cord, where ſome of the conſtituent threads are longer and therefore looſer than others. The end of the navel-ſtring which is next the placenta, is always leſs twiſted, and more uniform than the end which is next the fœtus.

“ Whatever be the cauſe, in moſt which I have attended to, the twiſting of the navel-ſtring has been in the ſame direction, *viz.* ſuch as would be produced in turning the child round upon the navel, as a centre, by puſhing its head towards the right ſide, and its feet to the left. In two and thirty preparations now before me, four only are twiſted the contrary way; and of the twenty-eight which are twiſted in the common way, three have the contrary twiſt for ſome inches, at the extremity, which was towards the fœtus.” The veſſels appear to be ſtraight in young embryos. When the chord is very long, *true* knots are formed in it; as diſtinguiſhed from thoſe which ariſe merely from projections of particular veſſels. Theſe are not ſuppoſed in general to affect the communication between the mother and child, but Dr. Hunter thinks he has ſeen two caſes in which it was obſtructed from this cauſe. The true knots are ſometimes double, as if twice tied; and in very rare caſes treble.

The *urachus* is another part belonging to the umbilical chord; it is a ſmall fibrous ſtring aſcending from the fundus of the bladder to the navel, between the umbilical arteries, and growing more ſlender as it proceeds. In the navel-ſtring it is hardly perceptible, except near the fœtus; it is like a fine thread, a little more white and opaque than the reſt. When once found near the fœtus, it may be traced, with a little trouble, nearly the whole length of the ſtring. This part is a canal in the embryo of animals, leading from the bladder to the allantois; but the latter membrane not exiſting in the human ſubject, the urachus is ſolid. Portal, who has inveſtigated the matter very attentively, found the urachus to conſiſt of four threads in embryos of five and ſix months. Theſe paſs together from the navel to the bladder; then ſeparate and expand over the latter organ. In the eighth and ninth month, theſe threads can hardly be ſeparated. The urachus altogether is largeſt in the youngeſt embryos.

The covering of the navel-ſtring, which is ſmooth and poliſhed, is conſidered to ariſe from a reflection of the amnios. Both that membrane and the chorion are firmly adherent to the chord, at its connection with the placenta; and the covering of the chord itſelf is moſt firmly connected with the ſubjacent ſubſtance, ſo that it cannot be ſeparated like a diſtinct membrane. The integuments of the abdomen are continued for a ſhort ſpace over the chord, and there is an abrupt line obſerved at their termination, beyond which not even the cuticle is continued. The ſeparation is much more ſtrongly marked, when the integuments are minutely injected, by the ſudden ending of the injection, no veſſel extending into the chord. The tying of the chord without the leaſt pain is a ſufficient proof that it has nothing to do with the ſkin.

The ſtrong connection between the abdomen of the child, and the chord, is produced by the three umbilical veſſels, penetrating the tendinous opening of the linea alba. They run externally to the peritoneum, which lies behind them entire and unperforated. The oppoſite end of the funis is connected with equal ſtrength to the placenta, both by the continuation of the veſſels into that body, and by the cloſe adheſion of the chorion and amnios.

Beſides the veſſels, the urachus, and the coat of the navel-ſtring, it contains nothing but a fine cellular ſubſtance, loaded with a tranſparent ropy fluid, giving the part both firmneſs and bulk. By touching the cut ſurface of the freſh funis, and removing the finger ſlowly, we ſee the fluid ſo tenacious and ductile, as to be drawn out into fine threads ſome inches in length. When it has been kept ſome days, the fluid loſes entirely that glutinous quality, and tranſudes like water; by which means the ſtring loſes much of its bulk. In this ſtate, if a ſmall blowpipe be puſhed into the interſtices of the veſſels, and proper ligatures be made, the whole interſtitial ſubſtance may be rendered emphyſematous and white. In this condition it may be dried, and then cut up to ſhew the cellular ſubſtance more diſtinctly. The great variety that is obſerved in the thickneſs or ſize of the navel-ſtring in different parts, and in different caſes, depends principally on the quantity of the cellular ſubſtance, and not on the bulk of the child.

Dr. Hunter thinks that “ the winding courſe of the veſſels in the navel-ſtring prevents their being much affected by any ſtretching force, and the firmneſs of the interſtitial ſubſtance, protects them againſt dangerous compreſſion. Theſe accidents might otherwiſe perhaps have occaſioned frequent miſchief, eſpecially where there is a large child, and a ſmall quantity of the liquor amnii. In ſuch a caſe the navel-ſtring paſſing under the arm or ham, or in the groin, might have been compreſſed, ſo as to prevent the return of the venous blood at leaſt. The ſame thing might have eaſily happened, where a knot is formed upon the navel-ſtring.”

The umbilical arteries divide in the placenta into ſmaller and ſmaller ramifications; and their ultimate branches communicate with the umbilical veins; injected fluids at leaſt return very readily by this courſe. The vein is made up by the union of the minute branches into larger and larger trunks. In the early periods of pregnancy, the umbilical veſſels branching out very minutely, conſtitute the flocculi of the chorion.

Placenta.—This, together with the membranes, makes a complete bag lining the uterus, and containing the child. As Dr. Hunter has done much in elucidating its ſtructure, and has given a very good account of the ſubject, we ſhall avail ourſelves chiefly of his labours.

Its figure is commonly round and flat; it is about an inch in thickneſs and a ſpan in breadth. It grows gradually thinner towards the edge, ſo as to render the change from the placenta to the membranes more imperceptible. When the cellular part is well filled with wax, or any fluid, it is at leaſt two inches thick. Its ſhape is often oblong or triangular, or irregular; and ſometimes there is a ſmall lobe or two entirely diſtinct from the reſt. The outer ſurface, which adheres to the womb, and is therefore naturally convex, is rough, tender in its ſubſtance, commonly covered with blood, lightly ſubdivided into ſmaller conſtituent lobes, and, to a common obſerver, apparently poſſeſſing no blood-veſſels, or at leaſt none of any conſiderable ſize. The internal ſurface, naturally more or leſs concave, is gloſſy, hard or compact in its texture, and beautifully marked with the ramifications of the umbilical veſſels. The navel-ſtring, which produces theſe branching veſſels, is inſerted ſometimes into the very centre, but more commonly a little nearer the edge, and often into the very edge of the placenta. In four different inſtances, Dr. Hunter ſaw the navel-ſtring terminate on the inſide of the membranes, at the diſtance of five or ſix inches from the placenta. In all theſe caſes the umbilical veſſels parted from one another even to conſiderable diſtances in their courſe upon the membranes, and came to the edge and inner ſurface of the placenta at different places, even at the oppoſite parts. The termination or inſertion of the navel-ſtring, wherever it happens to be, makes the centre of ramification for the large veſſels on the internal ſurface of the placenta.

The human placenta, like that of quadrupeds, is a compoſition of two parts intimately blended, *viz.* an umbilical or infantile, and an uterine portion. The former is made up by the ramification of the umbilical veſſels of the fœtus; the other is a certain portion of the decidua, produced, as we have already deſcribed, from the ſurface of the uterus. The umbilical portion of the placenta is made by a regular ramification of the arteries and veins of the navel-ſtring into ſmaller and ſmaller branches, without any lateral anaſtomoſis, ſo that when unravelled by gentle putrefaction, motion, and waſhing, this part takes on the appearance of a tree whoſe branches divide to almoſt infinite minuteneſs, not only towards its outer ſurface, but every where through its ſubſtance.

The two umbilical arteries anaſtomoſe freely by a canal of communication juſt where they are going to branch out upon the placenta, ſo that by injecting one of them, the other is readily filled alſo. Every branch of an artery is attended with a branch of a vein; theſe cling to one another, and frequently, in the ſubſtance of the placenta, entwine round one another as in the navel-ſtring.

Injections prove, both in the human ſubjects and in quadrupeds, that the umbilical arteries terminate in the veins of the ſame name, and not in the veſſels of the uterus; and that the blood paſſes from the arteries into the veins, as in other parts, and ſo back to the child again. If the placenta be whole in all its ſubſtance, which is ſeldom the caſe, and its blood-veſſels be pretty well emptied of their blood, any ſubtile injection thrown into an artery will fill the arterial ſyſtem through the whole ſubſtance of the part to an amazing degree of minuteneſs, and return ſo freely by the veins as to fill them very generally and equally. In the ſame manner the whole umbilical ſyſtem may be filled by injecting the vein, the fluid returning from the veins into the arteries. In both theſe experiments the injected fluid is confined to the umbilical vaſcular ſyſtem, none eſcaping at the external ſurface of the placenta, neither by large nor ſmall orifices, whether of veins or arteries.

When a placenta is finely injected, and then ſteeped, and frequently waſhed in clear water, it is evident that the umbilical veſſels do not reach even the outer ſurface of the placenta, but are only ſeen through a membrane (decidua,) which covers all that ſurface. It is rough or ragged, like the inner ſurface of the uterus, to which it adheres, and by its whiteneſs becomes very diſtinct from the vaſcular injected part of the placenta, over which it is ſpread. It becomes ſtill more diſtinguiſhable when the part is put into ſpirits, which render it more opaque and whiter. This membrane is an effloreſcence or production of the inner membrane of the uterus, and is analogous to the uterine fungi of quadrupeds. It receives no veſſels, demonſtrable by the fineſt injections, from thoſe of the navel-ſtring, yet it is full of both large and ſmall arteries and veins. Theſe are all branches of the uterine veſſels, and are readily filled by injecting the arteries and veins of the uterus; and they all break through in ſeparating the placenta from the uterus, leaving correſponding orifices on the two parted ſurfaces.

This decidua, or uterine portion of the placenta, is not a ſimple thin membrane expanded over the ſurface of the part, it produces a thouſand irregular proceſſes which pervade the ſubſtance of the placenta, as deep as the chorion or inner ſurface; and are every where ſo blended and entangled with the ramifications of the umbilical ſyſtem, that no anatomiſt will perhaps be able to diſcover the nature of their union. While theſe two parts are combined, the placenta makes a pretty firm maſs; no part of it is looſe or floating. But when they are carefully ſeparated, the umbilical ſyſtem is evidently nothing but looſe floating ramifications of the umbilical veſſels, like that vaſcular portion of the chorion which makes part of the placenta in a calf; and the uterine part is ſeen ſhooting out into innumerable floating proceſſes and rugæ, with the moſt irregular and moſt minutely ſubdivided cavities between them that can be conceived. This part anſwers to the uterine fungus of the quadrupeds. In a placenta at nine months the two conſtituent parts can only be ſeparated by ſome degree of putrefaction, and gentle rubbing and waſhing; but this operation always deſtroys the uterine portion, which is more tender, and yields to putrefaction ſooner than the other. In the placenta of an earlier age, the union of the two conſtituent portions is leſs intimate, and they may both be preſerved very entire, like the vaſcular chorion and fungus of the quadruped. Dr. Hunter ſeparated them in a conception of four months, and left the uterine portion attached to the inſide of the uterus.

The two portions of the placenta are ſo interwoven with each other as to leave innumerable ſmall vacuities, with free communications, through the whole ſubſtance. If this cellular ſtructure be inflated or injected, the placenta, like the corpora cavernoſa penis, acquires a very conſiderable increaſe of thickneſs, and ſubſides again when the fluid eſcapes. This cellular receptacle in the placenta cannot be completely filled after it has been parted from the uterus, becauſe then the fluid, which we may by any contrivance throw in, will be diſcharged at innumerable orifices on the outer ſurface of the placenta; but while it remains attached to the uterus, all the cells may be eaſily and completely filled by injecting any fluid into the arteries or veins of the uterus. Theſe veſſels, and theſe only, have a demonſtrable communication with the ſpongy cells of the placenta, which receive the maternal blood from the arteries of the uterus, and give it back into the veins of that part. Both theſe veſſels paſs in the decidua, and the larger branches of both, with little or no ramification, terminate abruptly in the cells. The arteries are all much convoluted and ſerpentine; the larger, when injected, are almoſt of the ſize of crow-quills. The veins have frequent anaſtomoſes, paſs in a very ſlanting direction, and generally appear flattened; ſome of them are at leaſt as big as a gooſe-quill, and many of them are very ſmall. They are very numerous round the edge of the placenta, and many run for a little way, in the direction of tangents to the circle, in the very angle between the membranes and the placenta.

In ſeparating the latter part from the uterus, which can be effected with very ſlight force, all theſe veſſels are neceſſarily torn through; and then each broken veſſel has an open mouth on the inner ſurface of the uterus, and a correſponding orifice on the outer ſurface of the placenta. They may be readily obſerved on a freſh placenta, as ſoon as it has come away in a common labour. Air blown into the cellular part by thruſting in the end of a blow-pipe, ruſhes out readily by the open mouths both of the arteries and veins.

While the placenta remains adhering to the uterus, injection will paſs either from the uterine arteries or veins into the cells of that organ; and, after filling theſe cells, it returns by the oppoſite order of veſſels to that by which it was thrown in. Hence, if we wiſh to inject both ſyſtems in the gravid uterus, we ſhould fill the firſt only moderately, and then the other.

The venous ſyſtem of the decidua and uterus may be filled with air from the cells of the placenta. Introduce a blunt probe through a ſlit in the coat of the navel-ſtring, and force it into the cells of the adjacent part of the placenta; then, withdrawing the probe, inſinuate an injecting pipe, and tie it firmly with a broad thread round the navel-ſtring. By that pipe you may fill the whole placenta uniformly in its cellular part, and likewiſe all the venous ſyſtem of the uterus and decidua, as readily and fully as if you had fixed the pipe in the ſpermatic or hypogaſtric vein; ſo ready a paſſage is there reciprocally between the cells of the placenta, and the uterine veſſels. It is as much reciprocal, and more largely open, than between the corpus ſpongioſum and the veins of the penis.

From all his experiments, repeatedly and diligently made, Dr. Hunter concludes, that the human placenta, like that of the quadruped, is compoſed of two diſtinct parts, though blended together, *viz.* an umbilical, which may be conſidered as a part of the fœtus, and an uterine, which belongs to the mother; that each of thoſe parts has its peculiar ſyſtem of arteries and veins, and its peculiar circulation, receiving blood by its arteries, and returning it by its veins; that the circulation through theſe two parts of the placenta differs in the following manner; in the umbilical portion the arteries terminate in the veins by a continuity of canal, whereas in the uterine portion there are intermediate cells, into which the arteries terminate, and from which the veins begin. Though the placenta be completely filled with any injection thrown into the uterine veſſels, none of the wax finds its way into any of the umbilical veſſels; and in the ſame manner fluids injected into the umbilical veſſels can never be puſhed into the uterine, except by rupture or tranſudation.

Several views of the arteries and veins, which paſs from the uterus to the placenta, are exhibited in Dr. Hunter's plates; ſee Tab. 15. fig. 1. Tab. 19. Tab. 29. fig. 1. and Tab. 30. and the ſame veſſels on the ſurface of the uterus in fig. 3. Tab. 10. and fig. 2. Tab. 28.

It has been ſtated already, that the human placenta is made of a ſingle maſs; but ſome varieties have been obſerved in this reſpect. It poſſeſſes ſometimes a ſmall appendix; or it may be made up of three or more ſmall pieces, united by means of the chorion. Wriſberg ſaw a placenta compoſed of ſeven pieces. Where there are twins, or three children, the placenta is uſually ſingle; but there may be two or three ſeparate ones united by the amnios, which forms the partition of the bags containing the children.

The Fœtus.—The proportions of parts, and conſequently the whole figure of the fœtus, differ very much before birth, from that which they poſſeſs afterwards; and they differ alſo very conſiderably at different periods of utero-geſtation. Influenced by their opinions of the beauty and due proportions belonging to the human frame in later ſtages of exiſtence, many have called the fœtus, in its early periods, ſhapeleſs and deſtitute of ſymmetry; not reflecting that a different figure and relation of parts belongs, in the order of nature, to the age we are ſpeaking of, and that this may ſtill be beautiful and ſymmetrical according to the ſtandard of that age. While the roſe is ſtill incloſed in the calyx, its appearance is very different from that which it exhibits when the petals burſt forth from their confinement, and the whole flower is diſplayed in its mature and perfect ſtate: yet we do not deem the roſe bud inelegant or imperfect in its form. We may affirm, on the ſame principles, that every age in the human ſubject is diſtinguiſhed by its peculiar kind of beauty; that the embryo, the fœtus, the infant, the youth, &c. poſſeſs their reſpective proportions, thoſe of each differing from the others; and conſequently, that an embryo may, with propriety, be termed beautiful, if its formation correſpond to the ſtandard of its age. It is true, indeed, that the fœtus in abortions is often ill-formed, being ſmaller than it ſhould be, deviating from the uſual proportions, or monſtrous; and, very probably, this mal-formation may be one of the cauſes why ſuch embryos die, and are ſeparated with the ovum from the uterus; juſt as we ſee that miſ-ſhapen or worm-eaten fruits ſeldom arrive at maturity, but have their further growth impeded by that very cauſe. To the ſame purport it is obſerved by Autenrieth, § 8, "that he found three monſtrous fœtuſes, out of nineteen, whoſe parts could be diſtinguiſhed; that Wriſberg met with two among five, which he examined; and Ruyſch two in twelve; the proportion of the whole being ſeven in twenty-nine. This large number, (if we conſider, at the ſame time, that all the collections of anatomical preparations abound with monſtrous fœtuſes, which have died immediately after birth, while adult monſters are extremely rare,) renders it very probable that nature employs the ſhort, but effectual means of extirpation, in order to preſerve the genuine figure of the human frame, and that one model only, of all thoſe into which the human frame may paſs, is endued with permanent vital powers." This author obſerves alſo, that a greater number of abortive embryos are of the male than of the female ſex; and this obſervation is confirmed by Soemmering, who extends it likewiſe to monſters.

It is extremely difficult to aſcertain at what exact time the fœtus of an ovum becomes viſible; becauſe it is almoſt always impoſſible, in the human ſubject, to aſcertain the date of the impregnation. Dr. Baillie ſtates, that he ſaw a preparation in the poſſeſſion of Dr. Combe, where, from peculiar circumſtances, it had been aſcertained that the conception was twenty-two days old, and where the fœtus was viſible, although extremely ſmall. In an abortion, which came away after the firſt ceſſation of the catamenia, diſſected by Blumenbach, and exhibited in the 4th table of his "Inſtitutiones Phyſiologicæ," the amnios was about the ſize of a large pea, but no veſtige of the fœtus could be diſcerned.

The following account of the ſucceſſive developement of the embryo is derived chiefly from Soemmering's work, "Icones Embryonum Humanorum," which is chiefly devoted to this ſubject, and exhibits a moſt beautiful ſeries of embryos from the earlieſt period to the fifth month.

Generally ſpeaking, the embryo grows the moſt rapidly in the firſt weeks after conception; the rate of its progreſs afterwards diminiſhes to the ninth month: this growth, however, does not proceed uniformly at all times. It is gradually retarded in the ſecond month, accelerated in the third; ſtopped again in the beginning of the fourth, and continued more rapidly from the middle of that month to the ſixth; from which time it is again retarded till the period of maturity. A ſimilar obſervation has been made concerning the chief viſcus of the embryo, by Walter, the ſon. (Annot. Acad. de hepate, § 8.) He found that the rapid and prodigious growth of the liver did not continue beyond the end of the fourth month. It appears, moreover, that different parts of the body of the embryo grow very differently; and that ſome arrive at a certain degree of perfection ſooner than others.

The younger the embryo, the larger is the containing ovum. That part, therefore, in proportion to the fœtus, is the largeſt, moſt capacious, thickeſt, and firmeſt, in the earlieſt periods after conception; and the ſmalleſt, thinneſt, and moſt tender, at the complete term of utero-geſtation. At the middle of pregnancy it exhibits an intermediate ſtate between theſe extremes.

In the firſt and ſecond months the embryo is completely bent; a little ſtraightened in the following month, and afterwards, as the limbs increaſe, convoluted into a kind of oval-ſhape. The head is brought forwards on the cheſt during the whole period of utero-geſtation. The younger the embryo, the greater is the bulk of the head, compared to that of the trunk; or, what is equivalent, the trunk is ſmalleſt at that time. The head muſt conſequently be the largeſt when it can be firſt diſtinguiſhed. In the firſt month the head conſiderably exceeds the ſize of the reſt of the body. Its growth goes on leſs rapidly after this time, and does not exceed that of the trunk; ſo that at the age of five months, it bears a moderate proportion to the body. The younger the embryo, the ſmaller is the face, in compariſon to the cranium. The pyramidal proportions of the temporal bones are particularly large in the firſt month.

The neck, correſponding in ſome degree to the ſize of the head, is large and ſhort; ſo ſhort, indeed, that it can hardly be recognized at all in the firſt and ſecond months, being marked by the ſlighteſt conſtriction. It is ſcarcely diſtinguiſhable before the third month, on account of the head being bent forwards.

The extremities are ſmalleſt, in proportion to the trunk, in the youngeſt embryo. They firſt ſhoot out from the trunk in the form of hemiſpherical tubercles, like buds from a tree; are protruded a little further, and elongated in the ſecond month; at which time, the upper limbs may be diſtinguiſhed into arms and hands, and the lower into legs and feet. Then the fingers ariſe, like little papillæ from the hands; the arms and fore-arms being more developed; at the ſame time thighs, legs, and feet, may be diſtinguiſhed in the lower limbs, but the latter are ſtill without toes. Theſe, however, ſhoot out at the end of the ſecond month, the fingers being at the ſame time elongated. In the three firſt months the upper limbs exceed the ſize of the lower ones; they become nearly equal in the fourth; and in the fifth the lower ones have acquired that ſuperiority which they afterwards retain.

The lower part of the ſpine is at firſt curved round towards the belly, ſo as to reſemble ſomewhat the tail of a quadruped, when thrown between the hind legs. This prominence, ſometimes called *tuber coccygeum*, is largeſt in the two firſt months, projecting beyond the lower limb, ſo as to give the ſpine a keel-like form. It gradually diſappears in the third month, as the lower limbs are elongated.

The eyes are firſt obſerved, of the organs of ſenſe, and are larger and more prominent as the embryo is younger. They are ſeen very diſtinctly in a beautiful and, as it ſhould ſeem, perfectly formed fœtus of the firſt month, not larger than a middle ſized pea, repreſented by Soemmerring. They may always be recognized, in the very youngeſt embryos, by a deep black circle. Before the ſecond month either the eye-lids are open, or ſo thin, that the black pigment of the bulb is diſcerned through them. Soemmerring thinks that the eye-lids are really open until about the tenth week, when they are cloſed. After that time he has always found them firmly ſhut, and the ſlit between them ſhorter than the diameter of the globe. The circle of the iris, which is of the deepeſt black, is completed ſooner on the outer than the inner ſide.

Very ſmall pores are ſeen in the ſituation of the external ears about the ſeventh or eighth week; the middle of the helix then riſes from the head, and is followed ſucceſſively by the tragus, antihelix, antitragus, lobulus, and upper part of the helix. The ears are completed by the formation of the concha and ſcapha in the fifth month. Their proportions are ſtill very different from thoſe of the adult. Two ſmall holes at firſt occupy the ſituation of the noſe, which itſelf gradually ſhoots out about the ſeventh week; the dorſum, alæ and ſeptum are diſtinguiſhable in the eleventh week. The mouth is largeſt in the firſt months; and is open, without any lips. The latter parts are diſtinctly formed about the eleventh week, and are firmly approximated, ſo as to cloſe the mouth, from the third month.

The genital organs, ſcarcely diſtinguiſhable in the firſt weeks, have acquired a conſiderable ſize at the commencement of the third month. The penis is large and prominent about the twelfth week, and the glans uncovered; the ſcrotum is ſmall and empty until the 9th month. Sometimes it is looſe, and diſtended with water; ſometimes corrugated. A ſmall ſlit is ſometimes diſcerned in the female in the ſecond month. The clitoris is large and prominent in the third month, like the correſponding organ of the male; ſo that a female embryo, viewed laterally, might be miſtaken for one of the other ſex. About the fourth month the clitoris hangs more downwards, but is ſtill large even in the fifth.

The umbilical chord at firſt is ſhort, but large; it ſometimes equals the trunk in very ſmall embryos. Afterwards its length increaſes, but the relative breadth diminiſhes. Its ſurface is always unequal and knotted.

Soemmerring has remarked that the ſex of the youngeſt embryos can be diſtinguiſhed, independently of the genital organs, if they are well proportioned. The moſt ſtriking difference is found in the ſtructure of the thorax. That of the male is longer, more conical, formed of thicker ribs, and more prominent, with reſpect to the abdomen and pelvis, than that of the female. In the latter, not only is the whole thorax ſhorter, but alſo rather larger above, as far as the fourth rib, and therefore leſs conical. It is more diſtant from the pelvis, on account of the greater interval between the laſt rib and os innominatum, and leſs prominent, ſo that where the body is either erect or ſupine, the ſymphyſis pubis is the moſt prominent part in the female, and the thorax in the male ſubject.

The abdomen begins higher in the female, and is large and prominent, expanding towards the genitals: we might ſay that the female thorax is compreſſed, and the abdomen tumid.

The diſtinction is ſo obvious, in reſpect to the points now mentioned, that it will not only be readily obſerved in the well formed embryos carefully compared; but it may even be thought ſtrange that it ſhould have hitherto eſcaped obſervation. It will often be noticed, according to Soemmerring, in very ſmall embryos; and if we can aſcertain the ſex by the organs of generation, we ſhall readily perceive the diſtinction in the form of the cheſt.

The form of the head exhibits another ſexual diſtinction. It is on the whole larger in proportion to the body, but leſs rounded in the male than in the female: the occiput too is convex, ſo that the neck is hollowed in appearance, and the vortex is flattened. In the female the form is more globular, the occiput not prominent, and the neck conſequently not hollowed, and the vortex ſpherical.

Some points of diſtinction may be ſeen alſo in the extremities; of which males have the ſuperior rather larger, the ſcapulæ ſtronger and more prominent, and therefore ſuitable to the ſtronger thorax of this ſex, the arms rather conical, the fore-arms more muſcular, the carpi broader, and the ends of the fingers more obtuſe. The lower limbs, adapted to the narrow male pelvis, are contracted above; the thighs are more ſlender, but the feet very ſtrong, with prominent malleoli and heels. The great toe exceeds the others in ſize very remarkably. The characters of the female are juſt the reverſe of theſe. The upper limbs are ſhorter, with the ſcapulæ more ſloping, the arms cylindrical, fore-arms ſlender, wriſts narrow, and ends of the fingers acuminated. The lower limbs, from the ſuperior breadth of the pelvis, are largeſt above, and diminiſh conically towards the knees; the heels and ancles are not prominent, and the great toe exceeds the others but ſlightly.

The ſpinous proceſſes of the inferior dorſal, and ſuperior lumbar vertebræ form a kind of projecting ridge in the back of the male, where the female preſents a depreſſion. The ſame difference is ſeen not only in the mature fœtus, but alſo in infants, and in the beſt proportioned boys and girls.

After deſcribing the progreſs of the embryo, and the differences of the male and female at this early period, Soemmering alludes to the much diſputed queſtion, whether the ſame powers of body and mind are beſtowed on all men, or whether there be not natural diverſity in theſe in different individuals, ariſing from original differences in the ſtructure of the frame. Attentive examination will ſhew that the bodies of embryos are marked by native traits of diſtinction, clearly recogniſable at a time, when neither food, education, habits, clothing, nor the operations of diſeaſe can have exerted any influence on them. Not to mention that fœtuſes are born, who, from too delicate an organization of the eyes, ſhun as the greateſt evil, that light, which is our firſt bleſſing; that imperfection in the ſtructure of the ears incapacitates ſome from the ordinary buſineſs of life; that others are almoſt cut off from human ſociety by deficient formation of the organs of voice; that mal-formation of the heart devotes ſome to an exiſtence of conſtant ſuffering, incapable of all exertion of body and mind, while deformity of the limbs circumſcribes the powers of others; that many are born without brain, and therefore utterly deſtitute of all mental faculties; putting all theſe circumſtances out of the queſtion, we notice great differences in the form and proportions of well made embryos. Wide differences exiſt in the ſhape, capacity, and firmneſs of that part of the head which lodges the brain; the countenance varies infinitely in the diſtance, ſize, and form of the organs of the external ſenſes; and there are marked diverſities in the volume of the cheſt, and in the ſtrength and form of the limbs.

To our account of the progreſſive developement of the different parts of the body, we ſhall ſubjoin a ſhort deſcription of the fœtus in its different periods. In the firſt month it conſiſts of a mere jelly; which is eaſily deſtroyed by very little touching, and evaporates almoſt entirely by heat. Authors have delineated embryos at the end of the firſt month of the ſize of a barley corn; or a pea. Soemmering gives a repreſentation of one very elegantly formed, no larger than a very ſmall pea. At this time the head is fully developed, and much exceeds the reſt of the body. The cranium is particularly large. The eyes and mouth are diſcernible. The figure of the whole is globular, the head and ſpine being ſtrongly bent towards each other. The poſition of the bodies of the vertebræ is diſcernible. The arms are two very ſmall tubercles; the lower extremities are the ſame; and the coccygeal tubercle is a larger prominence between the right and left of the latter limbs.

In the ſecond months the body becomes more firm and opaque, and its parts are more developed. The mouth and noſe are diſcernible; the eyes diſtinguiſhed by their blackneſs; and the ears can hardly be ſeen without the aid of the microſcope. The whole figure is ſtrongly incurvated, ſo that the coccygeal tubercle, which is larger than the rudiments of the lower limbs, nearly touches the head. At the end of this month the fingers and toes are diſcernible. Oſſification alſo commences; firſt in the clavicles, the large cylindrical bones, the lower jaw, frontal and occipital bone, &c. The body may now be half an inch long. The umbilical chord, very ſhort and thick, connects the child cloſely to the ovum. In the end of the third month the features are well formed. The forehead is very prominent. The general figure ſtill incurvated. The coccygeal tubercle diminiſhes and diſappears. The extremities are fully developed, and the fingers and toes perfectly diſtinct. The organs of generation are clearly ſeen; the penis and clitoris being very large, the nymphæ prominent, and the labia thick. The abdomen projects towards the umbilicus. Soemmerring has given a moſt exquiſite figure of a male embryo of about 12 weeks. The eye-balls are clearly diſtinguiſhable, larger than the opening of the lids. The noſe is well formed; and even the philtrum is clearly diſcerned in the upper lip. There is ſcarcely a veſtige of the coccygeal arch. The ſize and form of the ſcapula is evident, and the parts of the extremities in general diſtinctly ſeen; even the prominence of ſeveral muſcles, as the deltoid and biceps, gluteus major, vaſtus externus, &c.

In the fourth and fifth months the form and proportions approach conſtantly more nearly to thoſe which the body poſſeſſes in future. All the external parts are clearly diſtinguiſhable in the 14th and 15th weeks; except the hair and nails. Hitherto the fœtus was ſurrounded on all ſides by a large quantity of the water of the amnios; but as it grows now more rapidly than the ovum, it occupies the cavity of that part more completely. The head, in the fourth month, on account of its conſiderable ſize when compared to the body, ſinks conſtantly lower in the uterus. The fœtus comes completely in contact with its coverings in the fifth and beginning of the ſixth months, and conſequently the mother uſually begins now to feel its motions. On a very rare occaſion, Wriſberg ſaw clearly, for a few minutes, a ſlight motion of the arms and feet in a fœtus of 130 days. He could not diſcern any beating of the heart or arteries; neither did the muſcles of reſpiration act, when he inflated the lungs. In the ſixth month the membrana pupillaris of the eye is very viſible. The ſcrotum is ſtill empty and corrugated. Hair and nails are formed. The integuments ſtill hang rather looſely on the body, ſo that it has a lean and wrinkled appearance. In a fœtus of between 5 and 6 months, the length of the body was 10½ inches; and that of the head, from the vertex to the lower jaw, 3¼ inches.

The length of three fœtuſes, whoſe ages were 158, 162, and 170 days, varied from 16 to 19 inches; and their weight from 1lb. 10 oz. to 1 lb. 13 oz. All three came into the world alive: the pulſation of the arteries could be clearly felt, they reſpired, but cried feebly. They moved their limbs freely, could not ſuck, but ſwallowed milk which was poured into their mouths; and they lived ſeveral hours.

The ſize of the fœtus is conſiderably increaſed in the laſt three months. The greater comparative growth of the limbs makes it appear as if the head became ſmaller; the latter part is about one-third of the body in a newly born child. More fat is accumulated under the ſkin, ſo as to make the outline of parts more rounded.

The increaſe at this time is rather in breadth and thickneſs than in length. The hair grows longer, and the nails more firm. The membrana pupillaris diſappears, and the teſtes deſcend into the ſcrotum. A child of ſeven months can live a few hours only out of the uterus, and thoſe of eight months ſeldom live a fortnight.

The fœtus is fully developed and mature, ſo that it can live out of the uterus at the end of the ninth calendar month. Experience has ſhewn that children may live, when born a fortnight or three weeks before this time, if well taken care of; and it ſeems probable that a longer interval may elapſe before birth: but the neceſſary uncertainty of the mode of reckoning renders the point dubious. The proportions of parts are very different in the fully grown fœtus from thoſe of the adult. The head is extremely large; and the upper part of the trunk, and upper extremities, are very conſiderable when compared with the lower parts.

"The ſize and weight of a child's body at birth, ſays Dr. Hunter, are generally over-rated in this country; inſomuch that we are often told, even by thoſe who ought to know, of children weighing from 15 to 20 pounds. So far is this from being true, that I never knew an inſtance of a child which weighed 12 pounds, and the greateſt number a little above half that weight. Dr. Macaulay was at pains, at our hoſpital, to aſcertain the ordinary bulk of new-born children, by firſt weighing a great number indiſcriminately as they were born; and then by giving an order to our matron to weigh occaſionally all ſuch as were of a remarkable ſize in either extreme. Of ſeveral thouſands born in the Britiſh hoſpital at their full time, while the doctor's order was attended to, the ſmalleſt weighed about four pounds, the largeſt 11 pounds two ounces, and by far the greater number weighed from five to eight pounds, avoirdupois. In caſes of twins, it ſeldom happens that each attains the weight of a ſingle child. It has been remarked that the firſt is uſually the ſtrongeſt."

The meaſure and weight of the fœtus cannot be much depended on as criteria of its being mature or otherwiſe: yet if a child is much under between ſix and five pounds, and ſhorter than eighteen inches, it may be deemed immature. The following are alſo characters from which we draw the ſame concluſion. Thinneſs of the body, and mobility of the ſkin; a reddiſh livid colour of the ſurface, particularly in the palms and ſoles, probably from the blood ſhining through the thin integuments: and a fine woolly covering of the body. Mobility of the parietal bones, and great ſize of the fontanell. Thinneſs and ſhortneſs of the nails. The eyes being much cloſed, and the child not looking about at ſurrounding objects. Coldneſs of the hands and feet.

The growth of the child, during its reſidence in the uterus, is very conſiderable compared to its ſubſequent increaſe. According to Haller, (Element. Phyſiol. lib. 29. ſect. 4. § 17.) it increaſes in the firſt month to a bulk 300,000 times greater than its original ſize. In the ſecond month its increaſe is to 48 times the ſize it poſſeſſed at the end of the firſt. From this time to the full period it will only average an increaſe of 15 times for each month. At the end of the three firſt years, the proportion to the mature fœtus is as 14 to 5: and at the end of the 22 following years, the proportion to an infant of three years, as 8 to 1. The increaſe in the firſt month of exiſtence is to that of the laſt month of growth as 4,885,717 to 1, and the whole increaſe is from 1 to 108,000,000,000.

The number of twin-caſes to ſingle births, according to Süſſmilch, is as 1 to 65 or 70: by the ſame calculator, one inſtance of three children occurs in 6500 births; but probably it does not happen ſo often. Four children are extremely rare, and the caſes of five are ſtill more extraordinary. Twins live often enough; three children but ſeldom; and four, perhaps, never.

As a general obſervation, it may be ſtated that male children are larger than females. Dr. Clarke of Dublin has given us ſome intereſting facts on this ſubject from a regiſter of 20,000 births, in a paper contained in the 76th vol. of the Philoſophical Tranſactions. The weights of ſixty males and ſixty females were as follows, leaving out fractions:

Males.

℔s. - - -	4.	5.	6.	7.	8.	9.	10.
Number of children	0.	3.	6.	32.	16.	2.	1.

Females.

℔s. - - -	4.	5.	6.	7.	8.	9.	10.
Number of children	2.	9.	14.	25.	8.	2.	0.

He found the dimenſions of the head in the male to exceed thoſe of the female: thus, of 120 children, ſix only meaſured more than 14½ inches round the head; and all theſe were males. This greater ſize of males expoſes them to greater difficulty in the birth, and conſequently a greater number dies in that proceſs; one half more than of females. The proportion of males born to females was nine to eight: but, in conſequence of the greater mortality of the former in parturition, and the firſt days of exiſtence, the balance in favour of the male ſex, out of 20,177 children, was only 483 at the end of a fortnight, although originally 1177. In countries where polygamy is allowed, more females are ſaid to be born than males.

Poſition of the Child.—"The fœtus in utero," ſays Dr. Hunter, "is naturally contracted into an oval form, adapted to the figure and circumſtances of its habitation. The vertex of the head makes one end of the oval, and the nates the other; one ſide or edge of the oval is formed by the occiput, the back part of the neck, and the incurvated trunk; the other is made by the forehead, and the maſs of contracted and conglomerated limbs. The chin is cloſe to the breaſt, the trunk is bended forwards, the knees are cloſe to the fore parts of the hypochondria, the legs drawn to the back parts of the thighs, the feet or lower parts of the legs decuſſating each other; and the upper extremities contracted into the vacant ſpace betwixt the forehead and knees. The moſt common ſituation of the extremities is not to be determined, as they are found to be a little different in different diſſections; and in the living body they vary almoſt every moment: thence the hands are ſeen indiſcriminately on the head or face, or acroſs one another, or round the knees, or legs; and the legs are ſometimes extended, and the feet are placed by the face; or one is in that poſition, and the other contracted, and the foot downwards.

"The navel-ſtring, in paſſing from the child to the placenta, is often variouſly entangled with the extremities, and frequently winds once or oftener round the neck.

"When there is a conſiderable quantity of liquor amnii, the child takes the advantage of room, and the compoſition of its parts is not ſo cloſe or globular. In proportion as there is leſs room, its figure is more compacted and moulded to the ſhape of the cavity of the uterus. In two different caſes which I examined, there was ſo little fluid ſurrounding the child, though the waters had not been diſcharged, that the uterus had preſſed and moulded all parts of the child into a very ugly form, as if it had been made of dough: and in ſuch caſes the hands and more particularly the feet are liable to be compreſſed and twiſted into deformity, on account of their being projecting or pliant parts.

"With regard to the mother, the moſt common ſituation of the child, by far is, with its head downwards, and its nates at the upper part of the uterus. Once, perhaps, in twenty or thirty caſes, it is the contrary, and preſents, as they term it in midwifery, with its poſteriors. All the obſervations that I have been able to make in diſſections, and in the practice of midwifery, would perſuade me that the child's head is naturally downwards through all the later months of utero-geſtation."

By the poſition of the fœtus, as we have now deſcribed it, rolled up and compacted into an oval figure, it takes up the ſmalleſt poſſible room in proportion to its ſize. It diſtends the uterus too equably: and, in order to fulfil this object more completely, the intervals left by the inequalities of the child's body are filled with a fluid (the liquor amnii), and the whole is contained in membranes, ſo as to form a perfectly oval maſs, diſtending the uterus in all directions. Hence the fluid is more copious in younger embryos, becauſe they cannot be compacted into an oval maſs, and are too tender to diſtend the uterus.

The peculiarities of ſtructure, in various parts of the body, which diſtinguiſh the fœtus, will come under conſideration, moſt properly, when we deſcribe the different parts in which they are found. We ſhall, therefore, merely enumerate them on the preſent occaſion.

The ſurface of the body is covered every where with a firm ſebaceous and white ſubſtance, called by ſome vernix caſeoſa. This covering, which renders the whole body greaſy, cannot be waſhed off with plain water. It is inſoluble in alcohol, oils, or pure water: but ſome alkalies diſſolve part of it, and form a kind of ſoap. It has often been ſuppoſed that this is a ſediment from the liquor amnii; but that is very improbable, as the liquor amnii contains nothing unctuous, and there is none of it on the amnios or navel-ſtring. It muſt, no doubt, be a ſecretion from the ſkin.

The cutis, at firſt thin and gelatinous, is covered by a cuticle in the earlieſt ſtages. Proper fat is not formed under the ſkin before the fourth month; its place is occupied by a kind of jelly-like ſubſtance. Afterwards a pretty thick layer of fat is formed over the whole body, next to the ſkin; but there is very little about the viſcera or internal parts: little among the muſcles, or in the bony ſtructure. The ſkin has a very red and vaſcular appearance; and is ſaid to have this appearance, even in negroes, who are affirmed to change to the black colour a few days after birth. A ſoft woolly covering, ſeen particularly about the ſides of the face, the back, ſhoulders and ilia, in young embryos, diſappears in the mature fœtus.

The ſtate of the bones in the fœtus has been already alluded to in the article Bones. The jelly, of which the embryo is firſt compoſed, becomes more firm and conſiſtent in the fourth and fifth weeks. The materials of the parts which will afterwards be bones, are firſt changed from the gelatinous conſiſtence, common to all the organs, into cartilage, at firſt ſoft and tender, and aſſuming gradually firmneſs and elaſticity. Its figure repreſents that of the future bone. It loſes its tranſparency, and white opaque ſpots are diſcerned in it (*puncta oſſificationis*) about the ſeventh or eighth week after conception. Theſe are firſt obſerved in the clavicles, ribs, vertebræ, large cylindrical bones, lower jaw and other bones of the face, os frontis, and occipitis. Large veſſels are ſeen ramifying through the cartilage, and diſtributed on the oſſifying points; theſe ſecrete the oſſeous matter, which is there depoſited. In ſimple flat and ſmall bones there is a ſingle point, from which the oſſeous depoſit extends into the reſt of the bone. In moſt others, particularly ſuch as have an irregular figure, there are two, three, or more points, beginning at the ſame time, and extending in their circumference until they meet. Such bones conſiſt of certain pieces in the fœtus and young child, united by plates of cartilage. In other bones, particularly of the long kind, a principal point is obſerved at firſt, forming the body of the bone, or diaphyſis. Afterwards, ſmaller points ariſe, eſpecially at the ends, which had hitherto remained cartilaginous. Theſe are called epiphyſes, and, after their oſſification has proceeded conſiderably, they are ſtill connected to the body of the bone by a plate of cartilage. The oſſific points generally commence in the very middle of the cartilage, and extend thence into the cirumference. They differ in appearance in the different bones. In the flat ones, particularly of the head, they are thin reticulated ſcales, perforated with innumerable ſmall holes. The bony fibres, as they are called, extend, in theſe ſcales, in a radiated manner, from the centre to their circumference: in the long bones they are ſhort cylinders, with a ſmall depreſſion at each end, and poſſeſſing, apparently, parallel fibres: in the round bones they are globular granules; and in thoſe of irregular figure, irregular in their outline, and generally poſſeſſing ſeveral points.

At the time of birth the oſſicula auditus, labyrinth, and tympanum, are completely formed; all the other bones of the body are in a more or leſs incomplete ſtate.

Phyſiologiſts in all ages have attempted to explain how oſſification is effected, in what manner the cartilage is removed, and bony ſubſtance put in its place: which points we ſhall probably underſtand, when the hitherto unveiled myſteries of ſecretion and nutrition are completely laid open to our inſpection. In the mean time, inſtead of bringing forwards a ſeries of old hypotheſes, we ſhall juſt quote a paſſage from Albinus, (Annot. Acad. lib. 7. p. 76). "We may conjecture that there exiſts, from the firſt origin of the embryo, rudiments of the cartilages, however ſmall, ſoft, tender, and approaching to the nature of fluid: or at leaſt that ſomething is generated at that time, which is afterwards cartilage. But of the eſſential nature of cartilage or bone; of the manner in which cartilage is ſubſtituted in the place of bone; how either cartilage or bone is formed from our aliments; and what particular part of the fluids furniſhes the materials of this growth; we muſt confeſs ourſelves ignorant, and ſhall probably remain ſo."

The bones of the fœtus contain much more animal matter, and leſs earth than thoſe of the adult; they are conſequently of a greyiſh colour, and acquire more of a white or yellow hue, as they advance towards their perfect conſiſtence. The extremities of the long bones, on account of their numerous blood-veſſels, are dark coloured. The perioſteum is ſtrong and thick, and ſeparates eaſily. The place of marrow is ſupplied, in the embryo, by a mere gelatine, which acquires ſomewhat of a fatty or oily nature towards birth.

The younger the embryo, ſo much larger is the head in proportion to the trunk and extremities; ſo much ſmaller are the bones of the face compared to the cranium; ſo much larger the organs of hearing; and ſo much lower and flatter is the lower part of the face. The internal ſurface of the ſkull has no marks ariſing from the convolution of the brain, nor any grooves for the blood-veſſels. The cranium is at firſt merely membranous; the mode in which it is oſſified has been already conſidered under the article CRANIUM. We may juſt enumerate here, as peculiarities of the fœtal cranium, the want of the frontal, ſphenoidal, and maxillary ſinuſes, of the maſtoid proceſſes, and of the meatus auditorii externi, and the imperfect ſtate of the ethmoid ſinuſes. The condition of the jaws, with their contained teeth, has been conſidered at large in the article CRANIUM.

The os hyoides has ſcarcely began to oſſify at the time of birth.

The cavity of the thorax is proportionally larger than in the adult, and more conical. Blumenbach attempts to account for this ſize by the peculiarities in the circulation, and the conſequently greater bulk of the liver. The pelvis is very ſmall, ſo that there is no room in it for the urinary bladder. The individual bones of the cheſt and pelvis, as indeed of the reſt of the body, will be more particularly deſcribed in other articles.

In the upper extremities, the clavicles begin to be formed very early, and attain to a very large ſize, when the reſt of theſe limbs is extremely ſmall. Thus in the tenth week they are three times the ſize of the femora. The ſcapula is alſo conſiderable at an early period, and has a piece of oſſification double the ſize of that in the os innominatum. The carpus is completely cartilaginous, as is the tarſus in the lower limbs, excepting the aſtragalus and os calcis, each of which poſſeſſes a ſmall oſſific point. The oſſification proceeds afterwards more rapidly in the tarſus than in the carpus, probably on account of the erect ſtature of the human ſubject, and the ſhare which the tarſus has in ſupporting the body in that poſition.

All the bones of the embryo are uniform on their ſurfaces, where, in the adult, elevations and impreſſions are found.

The muſcles can hardly be diſtinguiſhed in the three firſt months, like the reſt of the ſoft parts they ſeem compoſed of a mere jelly. The fibrous texture becomes diſcernible in the following months; when we are able to diſtinguiſh tendons alſo. Such, at leaſt, is the obſervation of Wriſberg, in an embryo of $5\frac{1}{2}$ months. The tendons, which are fixed to the bones of the adult, terminate in the perioſteum and perichondrium of the fœtus, and come away entirely with theſe membranes.

It is obſerved, by Soemmerring, that the tendons of the recti abdominis are proportionally broader and ſtronger than in the adult. The pyramidales are conſiderably larger. There is a round opening in the linea alba for the paſſage of the umbilical veſſels. The muſcles of the internal ear are nearly complete at the time of birth; the intercoſtals and diaphragm are conſiderably developed at the ſame period, and the muſcles of the upper more than thoſe of the lower extremities.

The eyes are developed at a very early period, being diſtinctly viſible in the youngeſt embryos hitherto obſerved. They appear as black points at the end of the firſt month. The pigmentum is viſible from the firſt, and is particularly thick and black. It has been correctly obſerved by Hogarth, that no part of the body grows ſo quickly, and is ſo perfect in the fœtus, requiring no additional growth after birth, as the iris. The cornea, cryſtalline lens, and vitreus humor, have a reddiſh tint. The lens is ſpherical in its figure. That great peculiarity of the fœtal eye, the membrana pupillaris, will be deſcribed in the article EYE.

The external ears are developed rather late, as there is not the ſlighteſt trace of them at the end of the firſt month. The meatus externus is often filled up with the vernix caſeoſa. The membranous texture of the whole meatus; the covering of the membrana tympani by the membrana mucoſa; the attachment of that membrane to the annulus auditorius; the want of maſtoid cells are all further explained in the article EAR.

The formation of the noſe commences late; and the cavity is ſmall and very incomplete in the fœtus, as a neceſſary conſequence of the ſtate of the bones of the head at that time.

The thyroid gland is large and vaſcular in the fœtus.

The thymus, which is of very conſiderable ſize before birth, and gradually diſappears afterwards, will be conſidered under that article.

The lungs are ſmall, collapſed, of a red colour, and ſink in water.

The mammæ are large in proportion to the ſize of the body. The papilla is ſmall, and not yet ſurrounded by an areola. The breaſts of the male and female fœtus do not differ: they contain a whitiſh fluid, which can be forced out by gentle preſſure, and ſometimes flows ſpontaneouſly in children.

The abdomen is very large in the fœtus, and is drawn into a conical form towards the navel in young embryos. The great ſize of the abdomen may be accounted for by conſidering, that this cavity holds the bladder, and that the liver and renal capſules are very large. The diſtance from the end of the ſternum to the pelvis, in a newly born child, is one-third of the length of the body; in the adult it is not one-fifth.

In the alimentary canal of the fœtus, we obſerve an almoſt entire want of valvulæ conniventes in the ſmall inteſtine; and of appendices epiploicæ in the large. The appendix vermiformis is a gradual conical contraction of the cæcum. The inteſtines are more or leſs filled with a ſoft matter, of a yellowiſh green colour in the ſmall, and of a dark green, approaching to black, in the large, called meconium. There is very little of this near the ſtomach; it increaſes in quantity lower down, and is the moſt abundant in the large inteſtines. But in the early months, the latter part of the canal contains no meconium. It is not diſtinguiſhed by any peculiar taſte or ſmell.

The pancreas is large, and the liver of immenſe ſize in the embryo. The kidneys are alſo conſiderable, and lobulated on the ſurface. The renal capſules equal the ſize of the kidneys. The urinary bladder is very large, equalling the dimenſions of the ſtomach

The ſituation of the teſtis in the abdomen, and its paſſage from that cavity into the ſcrotum, will be conſidered when the teſtis itſelf is deſcribed.

The heart is proportionally large in the fœtus, and occupies a conſiderable part of the thorax. Hence, on expoſing that cavity, this viſcus comes immediately into view, and ſeems in a manner to cover the lungs. The foramen ovale, by which the two auricles communicate; and the equal ſtrength of the two ventricles, will be conſidered when the heart itſelf is deſcribed. The pulmonary artery of the fœtus divides into three branches, of which the middle is the largeſt. This is termed the *ductus arterioſus*, and it runs directly to join the aorta, immediately below the arch of that veſſel. It is often named after Botal, although Galen and others knew it. Its length is about equal to a finger's breadth. It conveys into the aorta a large part of that blood which paſſed from the right auricle into the right ventricle; more than half of it, according to Haller. This canal is cloſed very ſoon after birth, often within a few days. The umbilical veſſels have been already deſcribed in a former part of this article. The arteries are found obliterated from the navel to the bladder, very ſoon after birth, often within a very few days; near the bladder they are very much contracted, but not cloſed, and give origin to the arteries of the bladder. The umbilical vein, and ductus venoſus are cloſed in the ſame way. The mode in which the circulation is carried on through the parts now deſcribed, is repreſented in the article CIRCULATION.

The coverings of the brain are at firſt ſo thin and tranſparent, that this organ can be ſeen through them. It is almoſt fluid until the 5th or 6th month, and remains very ſoft even to the time of birth, ſo that its diſſection is difficult. It is always larger in proportion to the body, the younger the fœtus. The nerves are larger in proportion to the body.

Phyſiology of fœtal exiſtence.—Some remarks on this ſubject will be found in the article CIRCULATION. We have only to obſerve, further, on the ſubject of the connection between the mother and child, that the *mode* by which this is effected, notwithſtanding it has been a favourite ſubject of reſearch with the greateſt phyſiologiſts of all ages, remains ſtill a problem. The account which we have given of the ſtructure of the placenta, ſhews that the arteries and veins of the uterus have communications with the ſubſtance of the former organ; we are, however, entirely unable to ſtate *how* the blood of the mother, or any nutritive fluid, is admitted into the umbilical veſſels; although the obvious impoſſibility of the fœtus deriving the materials of its growth from any other ſource, leads us to conclude, without heſitation, that ſuch admiſſion muſt take place. The reader will probably think that the following quotation, containing Mr. Hunter's opinion, does not tend to elucidate materially this obſcure queſtion.

“ The blood, detached from the common circulation of the mother, moves through the placenta of the fœtus, and is then returned back into the courſe of the circulation of the mother, to paſs on to the heart.

“ This ſtructure of the placenta, and its communication with the uterus, leads us a ſtep further in our knowledge of the connection between the mother and fœtus; the blood of the mother muſt paſs freely into the ſubſtance of the placenta, and the placenta moſt probably will be conſtantly filled; the turgidity of which will aſſiſt to ſqueeze the blood into the mouths of the veins of the uterus, that it may again paſs into the common circulation of the mother; and as the interſtices of the placenta are of much greater extent than the arteries, which convey the blood, the motion of the blood in that part muſt be ſo much diminiſhed, as almoſt to approach ſtagnation.” (Obſ. on certain parts of the Animal Economy, p. 135.)

The exiſtence of the fœtus is purely vegetative. Conſtantly receiving the materials of its nouriſhment and growth from the juices brought to the placenta by the veſſels of the mother, it may be regarded as a new organ produced by conception, participating in the general life, but having its own peculiar life, which is, to a certain degree, independent of that of the mother.

The animal life, or that claſs of functions by which the animal is connected to the external world, has not yet commenced in the fœtus. Its ſtate therefore cannot, with any juſtice, be compared to that of a perſon aſleep, in whom theſe functions are only ſuſpended: but in the fœtus they have not begun.

The fœtus can have no ſenſations from the ſurrounding medium: its temperature being invariable, it can have no object of compariſon, which is eſſential to ſenſation. The ſenſes cannot act, becauſe none of the cauſes, which excite them, have hitherto operated. That of touch, being dependent on the others, and ſerving to rectify the concluſions which they tend to, muſt of courſe be inactive. This inaction of the ſenſes ſuppoſes a ſimilar ſtate of their nerves, and of the brain. Tranſmiſſion of impreſſions is the function of the former; perception of the latter: but neither of thoſe acts can take place when there are no objects to be tranſmitted or perceived. Memory and imagination flow immediately from perception: judgment ariſes from one of theſe three, and gives origin to the will. This connected ſeries of faculties has not begun in the fœtus, becauſe of the want of ſenſations. The brain is capable of acting, and poſſeſſes all the requiſites for action; it is not *excitability* but *excitation* that is wanted. The fœtus moves while contained as the uterus; and theſe motions are conſidered as ſymptoms of pregnancy. As all motion ariſes from ſome foregoing impreſſion, and as the ſenſes of the fœtus are completely inactive, it is difficult to aſſign a ſatisfactory cauſe for theſe movements of the child.

The functions of organic life, or thoſe by which the nutrition and growth of the body are effected, muſt commence almoſt as ſoon as the fœtus is conceived. The matter of nutrition ariſes in its body in an aſſimilated ſtate, having been prepared by the mother: it enters immediately into the circulating ſyſtem, without traverſing the digeſtive organs, then nearly inactive. The organs of excretion, which decompoſe the body, as the lungs, ſkin and kidnies, are alſo almoſt inert. The ſecretions have hardly commenced.

To the great ſimplicity of the aſſimilative proceſs in the fœtus, let us add the remarkable activity of the organs employed in it; an activity which depends on the greater proportion of their vital powers. The whole force of the animal economy ſeems to be concentrated on the two ſyſtems of circulation and nutrition; the proceſſes of digeſtion, reſpiration, ſecretion, and exhalation being exerciſed, at moſt, but feebly: the diminiſhed energy of the latter being made up by the increaſed power of the former. If we conſider, moreover, that the organs of the animal life, condemned to a neceſſary inaction, are gifted with a very ſmall ſhare of vital powers; we ſhall ſee that nearly the whole of that living energy, which is deſtined, in the ſequel, to animate all the ſyſtems of the body, is, in the fœtal ſtate, concentrated upon thoſe which are concerned in building up the various parts; and conſequently that the functions of nutrition and growth poſſeſs, at this age, an energy vaſtly ſuperior to that of any others.

We may refer the reader to a great number of works on the ſubjects of the preceding article. In the eighth volume of the Elementa Phyſiologiæ, Haller has diſplayed his uſual erudition and judgment in a complete collection of all the facts aſcertained previouſly to his time. Dr. Hunter's Anatomia uteri humani gravidi, folio, and Soemmerring's Icones embryonum humanorum, folio, 1799, contain a perfect ſeries of repreſentations of the human ovum, and its contents from the earlieſt time to its maturity. Dr. Hunter's Anatomical deſcription of the human gravid uterus and its contents, publiſhed after his death by Dr. Baillie, 4to. 1794, is a clear and plain deſcription of the ſubject. We may mention further, Wriſberg deſcript. anat. embryonis, obſervationibus illuſtr. 4to. Gött. 1764, or, in the third volume of Sandifort's Theſaurus; alſo, his remarks on the ſtructure of the ovum in the Göttingen Commentaries for 1773 and 1783. Roderer De pondere & longitudine infantum recens natorum in the Göttingen Commentaries for 1753; and Wriſberg de vita fœtuum humanorum dijudicanda,

canda, in the ſame work for 1773. Autenrieth ſupplementa ad hiſtoriam embryonis humani, Tubingen, 1797, 4to.

On the compariſon of the ſtructure of the fœtus and adult, ſee C. I. Trew de differentiis hominis nati et non nati, Altdorf, 1736. I. G. Roderer de fœtu perfecto, Straſburg, 1750. Portal in the Mem. de l'Acad. des Sciences de Paris 1770. A. and F. Roeſslein de differentiis inter fœtum et adultum, 4to. Straſburg, 1783. On the nutrition of the fœtus, ſee Leveillé ſur la nutrition du fœtus conſideré dans les mammiferes & les oiſeaux. Paris an. 7. & Lobſtein diſſertation ſur la nutrition du fœtus, Straſburg, 4to. 1802. The moſt complete book on the whole of the ſubject, that is, the ſtructure and developement of the ovum, and the anatomical peculiarities of the fœtus, is F. G. Danz Grundriſs der Zergliederungs kunde des ungebohrnen kindes in den verſchiedenen Zeiten der Schwangerſchaft. 2 vols. 8vo. 1793, which contains moſt abundant references to all the ſources of information on every part of the ſubject.

Embryo, in *Vegetable Phyſiology*, εμβρυον, a *fœtus*, or *infant*, the Corculum of Linnæus, under which term we have already mentioned it, is the moſt eſſential part of a perfect ſeed. When ſexual impregnation has not taken place, this organ is defective, however perfect all the other parts of a ſeed may be, as in the *Cycas revoluta* which bore fruit at the biſhop of Wincheſter's, and is deſcribed and figured in the Tranſactions of the Linnæan Society, v. 6. 312. t. 29, 30. Here every part of the fruit and ſeed was apparently in the higheſt perfection, except that a ſmall cavity was only found in the place of the embryo, a defect doubtleſs to be attributed to the abſence of a male plant of the ſame ſpecies. The ſame has been obſerved in cucumbers and melons, whoſe fruits are not the worſe in flavour on account of ſuch a deficiency, though dates, when unimpregnated, are known to be much inferior in quality. The embryo or corculum is very conſpicuous in the walnut, the garden bean, pea, lupine, &c. In a very poiſonous plant, the *Jatropha Curcas*, figured in Gærtner, t. 108. f. 1. this author mentions as a remark of Mr. Boyle, that the nucleus or albuminous part of the ſeed may be eaten with impunity, if the embryo and cotyledons, or rather perhaps *plumula*, be taken away. This ſame circumſtance was pointed out by the natives of Sierra Leone to Dr. Afzelius and his companion Borone. The internal ſtructure of the embryo, before it begins to vegetate, is obſerved by Gærtner to be remarkably ſimple, conſiſting of an uniform medullary ſubſtance, encloſed in its appropriate bark or ſkin. When the vital principle is excited to action, veſſels are formed, and parts developed, which ſeemed not previouſly to exiſt, as in the egg of a bird. The embryo is generally ſituated within the ſubſtance of the ſeed, but not always, being entirely external to the body of the ſeed, though within the ſkin, in the natural family of graſſes or corn. In umbelliferous plants it occupies the very centre of the ſeed, and in that family its poſition is reverſed; whereas in compound or ſyngeneſious flowers, though equally central, it is erect with regard to the baſe or inſertion of the ſeed. In the date and ſome other palms the embryo is lateral and horizontal; while in the cocoa-nut and others it is erect, in the centre of the baſe of a large *albumen*. Its direction is either ſtraight, curved, or even ſpiral. Its form is moſt ſimple in plants that have only one cotyledon, or rather no proper cotyledon at all. S.

Embryo-*worms*. It is a matter of no ſmall curioſity, to obſerve the arrangement of the multitudes of the embryo-worms, as they are lodged in the bodies of the viviparous two-winged flies.

An accurate diſſection of one theſe little animals, ſhews very plainly the parts where the embryo-worms are incloſed. This diſſection is eaſily made with a pair of fine pointed ſciſſars, taking off the whole upper ſhell of the body from the lower; and that part which covers the belly may be turned back upon the corcelet, without diſturbing the internal parts by the operation; and the form and arrangement of the parts which contain the embryo-worms in theſe, will be found very different from that of thoſe which contain the eggs in the common flies. Baker on the Microſcope, p. 115. 416. 417. 428. 430.

EMBRYOPTERIS, in *Botany*, from εμβρυον, an *embryo*, and πτερον, a *wing*, as appears from an examination of Gærtner's figure; though, from the conſtruction of the word, it ſeems to be derived from πτερις, a *fern*, or *brake*. Hence this name, as it at preſent ſtands, is liable to a double objection, as being compounded of one previouſly eſtabliſhed, *Pteris*, and ſtill more as conveying a falſe idea of its own application. *Embryopterum* would have been correct and unexceptionable, and we ſhould without ſcruple have adopted ſuch an alteration; but the name is altogether ſuperfluous, the plant in queſtion being a *Dioſpyros*, under which head its generic character may be ſeen. We have, therefore, here only to add to that liſt of ſpecies the following.

Dioſpyros glutinifera, Roxb. MSS, (Embryopteris peregrina; Gærtn. v. 1. 145. t. 29. f. 2. E. glutinifera; Roxb. Coromand. v. 1. 50. t. 70.) Stamens numerous. Leaves oblong, paliſh beneath. Seeds eight or ten. This is a middle-ſized evergreen tree, growing in the moiſt cool valleys among the mountains of the northern Circars, flowering in March and April. The natives call it Tumika, and eat the fruit, which Dr. Roxburgh deſcribes as ſtrongly aſtringent, and not palatable. The Malays name it Mangoſtan-utan, and the Dutch Lym-appel. The wood is of an indifferent quality, and not much uſed. The *branches* are ſmooth. *Leaves* alternate, ſtalked, oblong, ſometimes inclining to elliptic, and occaſionally a little heart-ſhaped at the baſe; entire, ſmooth, paliſh beneath. *Flowers* white; the males in ſmall axillary cluſters; females on a ſeparate tree, ſolitary and larger. *Berry* globular, about two inches in diameter, of a ruſty yellow, and covered with a ruſty farina when ripe. Gærtner miſtook the top of the fruit for the baſe, and hence erroneouſly deſcribes the calyx as ſuperior. He alſo miſtook the radicle of the embryo for a ſimple cotyledon, but his profound knowledge led him to ſuſpect that a cavity in the other extremity might be the real ſeat of the embryo, and that the circumambient ſubſtance was conſequently a vitellus. We preſume this cavity to have ariſen in the plumula, from a ſhrinking of the parts, after the vital principle was extinct, his ſpecimen being an old one, and therefore his ſuſpicion was, ſo far, well founded. He deſcribes the *albumen* as gelatinous in its centre, and diſſolving in water, to which Dr. Roxburgh's ſpecific name, and the Dutch appellation, both ſeem to allude. S.

EMBRYOTHLASTES, Εμβρυοθλαστης, in *Surgery*, an inſtrument wherewith to cruſh the bones of an embryo, or dead child; ſo as to make it eaſier of extraction, and prepare it for the embryulcus, to draw it out of the womb.

EMBRYOTO'MIA, from εμβρυον, *a fœtus*, and τεμνω, *to cut*, the operation of cutting into the womb, in order to extract the fœtus. See Cæsarian *Section*.

EMBRYULCUS, from εμβρυον, and ελχω, *to draw*, an inſtrument uſed in extracting dead children. See Crotchet.

EMBS, or Ems, in *Geography*, a ſmall town of Germany, which, till the peace of Luneville, belonged in part to the landgrave of Heſſe Darmſtadt, and in part to the prince of Naſſau Dietz, to whom it has been ceded; is chiefly remarkable for five ſulphureous baths in its neighbourhood.

Embs, or *Hohenembs*, a ſmall diſtrict of Germany, in the circle of Swabia, ſouth of the county of Bregentz and the lake of Conſtance, about 10 miles long and 5 broad, erected into a county by Charles V.

EMDEN, or Embden, a town of the kingdom of Holland, capital of the department or province of Eaſt Frieſland, which, till the year 1807, belonged to Pruſſia, to the ſovereign of which it had been ſold by the United Provinces of the Netherlands, in 1744. It is ſituated on the Ems, not far from the ſea, and near the lake Dollart; 30 miles N.E. of Groningen. N. lat. 53° 20'. The harbour is commodious; it holds 400 veſſels.

Emden had gained conſiderable commercial importance, from having been declared a free-port by the king of Pruſſia, in 1751. Its ſituation was extremely convenient for the Dutch, to carry on their commerce with the greateſt ſecurity in time of war; particularly during the late wars between England and France, when the Texel was blockaded by the Engliſh. Goods uſed to be forwarded, on the river Ems, to within a ſhort diſtance of Munſter in Weſtphalia; from which city they were conveyed by land-carriage to the interior of the continent, to Switzerland, and Italy. In the year 1781, the number of ſhips cleared outwards was 1025, inwards 1004; but in 1799, there entered at Emden inwards 3402 veſſels, and 2151 ſailed outwards. In 1784, Emden had 273 veſſels of the tonnage of 38,578 tons, beſides 43 veſſels for the herring fiſhery; in 1804, the number of ſhips employed in the carrying trade only, belonging to Emden, exceeded 500.

The population of Emden, in the year 1785, amounted to 7968 individuals, without the garriſon; in 1802, Emden counted 10,400 inhabitants. The herring fiſhery produced annually near 1000 tons of herrings. It employed 60 boats, and a great many hands among the lower orders of the people.

EMEGIAGEN, a town and fortreſs of Africa, in the empire of Morocco.

EMENDALS, an old term ſtill uſed in the accounts of the Inner Temple; where, ſo much in emendals at the foot of an account, on its balance, ſignifies ſo much in the bank, or ſtock of the houſe, for reparation of loſſes, and other occaſions.

EMENDATIO *Panis & Cerevisiæ*, the aſſize of bread and beer; or the power of ſuperviſing and correcting the weights and meaſures belonging to them. See Assize.

EMERALD. Of this mineral there are two diſtinct varieties: the true emerald, and the beryl or aquamarine, both of which we ſhall proceed to deſcribe.

True Emerald.—Emeraude Verte, *Fr.* Schmaragd, *Germ.*

The colour of emerald is pure priſmatic green, of various degrees of intenſity; but the deep-coloured varieties paſs occaſionally into graſs and verdegris-green, and the lighter ones into greeniſh-white. The only natural ſtate in which it has been hitherto met with is cryſtallized. Its primitive form is a regular hexahedral priſm; ſometimes the lateral edges are replaced by ſecondary planes, forming a dodecahedral priſm; or, the ſolid angles are replaced by ſmall triangular facets; or, the terminal edges are bevelled, ſometimes very ſlightly, and ſometimes ſo deeply as to preſent the appearance of terminal truncated pyramids. The length of the priſms ſeldom greatly exceeds their diameter. The cryſtals are middle-ſized and ſmall, rarely large: they are generally implanted, and ſometimes imbedded, and always occur in cluſters. The internal luſtre is vitreous and ſhining; the fracture is ſmall and imperfectly conchoidal, paſſing into obſcurely foliated. It is tranſparent or tranſlucent, and exhibits a double refraction. Its hardneſs is ſomewhat ſuperior to that of quartz. Sp. gr. 2.72 to 2.77.

It is fuſible *per ſe* before the blow-pipe, but with difficulty, into a ſemi-opake whitiſh glaſs. With borax it melts eaſily, and without efferveſcence. Its conſtituent parts, according to Vauquelin and Klaproth, are as follows:

	Vauq.		Klapr.
Silex -	64.50	—	69.
Alumine -	16.	—	15.
Glucine -	13.	—	12.5
Lime -	1.6	—	0.25
Oxyd of chrome	3.25	—	0.25
Oxyd of iron	0.	—	1.
Water -	2.	—	0.
	100.35		98.

It is at preſent found only in Peru, in the valley of Tunia or Tomana, between the mountains of New Granada and Popayan; and near Puerto Viejo, in the diſtrict of Manta, in the ſame province. It is ſaid to occur in veins, paſſing through argillaceous ſchiſtus, and other primitive rocks, and is accompanied by quartz, felſpar, black ſchorl, mica, calcareous ſpar, and iron pyrites.

Emerald is reckoned among the gems, and when of a fine colour, and without flaws, is highly eſteemed. The moſt magnificent ſpecimen known of this mineral was preſented to the church of Loretto, by one of the Spaniſh kings: it conſiſted of a maſs of white quartz, thickly implanted with emeralds, more than an inch in diameter.

The emerald is ſuppoſed by Dutens and others to have been unknown to the ancients; and it is certain, that ſeveral of their deſcriptions of the ſmaragdus are not at all correſpondent, except in colour, to the modern emerald. But among the twelve kinds of ſmaragdus, or rather pſeudoſmaragdus, enumerated by Pliny, one of them, and that the moſt valued, appears to be the real emerald. With regard to its colour, this naturaliſt ſays, "Nihil omnino viridius comparatum illis viret." He ranks it, in eſtimation, immediately after the diamond and pearl; and adds, that ſo pleaſing was its tone of colour, that by common conſent the engraver was ordered to ſpare it: "Quapropter decreto hominum iis parcitur, ſcalpi vetitis." The emeralds of the ancients were procured from Ethiopia; but theſe mines have now been for many ages forgotten and neglected; nor is it certain that any except the Peruvian emeralds are now extant. The only one that may with any probability be referred to an African origin, is that with which pope Julius II. adorned the papal tiara: for as this ſovereign died in 1513, and the enterprize of Pizarro againſt Peru did not take place till 1545, it is not unreaſonable to conclude that the emerald in queſtion is not an American one. There are two ſpecimens, which formerly obtained great eſtimation as invaluable Ethiopian emeralds, which the ſuperior accuracy of modern knowledge has ſtripped of their value, both in the eyes of the naturaliſt and of the jeweller. The one is a tabular maſs, of the weight of 28 *lbs.* now in the abbey of Reichenau, and which formerly belonged to Charlemagne: this Mr. Coxe has aſcertained to be green fluor. The other is the "Sacro cattino de Smeraldo orientale," which was depoſited in the treaſury of Genoa, and was not allowed to be ſeen except in conſequence of an order from the ſenate: in this the acute eye of M. Condamine

mine detected ſome air-bubbles, which induced him to conſider it as only green glaſs; and ſubſequent examination has fully confirmed his ſuſpicion.

Beryl, or *Aquamarine*—Emeraude verte bleuatre, Hauy. Edler beril, Wern. Its colour is mountain-green, paſſing into whitiſh-green, yellowiſh-green, wine-yellow, and honey-yellow, or blueiſh-green, paſſing into ſmall and ſky-blue. Its colours are almoſt always pale; and when two exiſt in the ſame cryſtal, they are generally arranged in alternate layers. The primitive form and varieties of cryſtallization are the ſame as thoſe belonging to the true emerald; but the actual and proportional length of the priſms is much greater. The lateral planes of the cryſtal are ſtriated longitudinally, ſo as ſometimes to give the priſm a cylindrical appearance. The joints perpendicular to the axis are generally very diſtinct, and moſt commonly are plane ſurfaces; but ſometimes, like thoſe of articulated baſalt, they are formed by a convex protuberance let into a cup-ſhaped concavity. Another ſingular accident to which this mineral is ſubject is, that a priſm, which at its lower end is ſolid, terminates occaſionally in a bruſh-like extremity, compoſed of numerous ſmall priſms. Sometimes a joint is ſo diſpoſed, that it is no longer perpendicular to the axis of the priſm; in conſequence of which, an elbow is produced, as if the priſm had been broken acroſs, and the pieces ill cemented together again. Sometimes, again, the axis of the priſm is perforated. The ſize of the cryſtals varies from capillary to 18 inches long by 2 or 3 in diameter. Its external luſtre is ſhining and gliſtening; internally, it is brilliant and vitreous. The croſs fracture is ſmall, and imperfectly conchoidal; the longitudinal fracture is foliated. It is commonly tranſparent, paſſing into tranſlucent; its hardneſs is nearly the ſame as that of the emerald. It is electric by friction, and often phoſphoreſcent. Sp. gr. 2.68 to 2.72.

According to the analyſes of Vauquelin and Roſe, it is compoſed of,

	Vauq.		Roſe.
Silex -	68.	—	69.
Alumine -	15.	—	14.
Glycine -	14.	—	14.
Lime -	2.	—	0.
Oxyd of iron	1.	—	1.
	100.		98.

Beryl occurs imbedded in primitive rocks, alſo in veins accompanied by quartz, felſpar, fluor ſpar, garnet, mica, and topaz. It is found in Brazil, in Saxony, in the ſouth of France, near the village of Barat, whence very large but ill-coloured cryſtals have been procured, and occaſionally in the higheſt mountains of Aberdeenſhire. But the fineſt ſpecimens of all come from Siberia, and are found chiefly in three places of this vaſt country.

Firſt, in the Uralian mountains, about 25 leagues to the north of Ekaterinbourg. The ſpecimens that come from this mine are of a ſmall ſize, but a very good colour.

Secondly, in the Altaic mountains, between the Ob and the Irtiſch. The cryſtals from this mine are large, and of a greeniſh-blue colour, but coarſe, and mixed with quartz.

Thirdly, in the granitic mountain of Odon Tchelon, in Daouria. This is by far the moſt intereſting and the richeſt mine. There are in fact three different mines at different heights on this mountain, from which beryls are procured: that ſituated the loweſt is in a maſs of ſemi-decompoſed granite, mixed with ferruginous clay and nodules of Wolfram; in this there are irregularly diſſeminated minute priſms of beryl, rarely exceeding an inch in length, and of a greeniſh-yellow colour. About 800 yards above this mine is an irregular vein of micaceous clay, from which are procured the moſt valuable cryſtals; their colour is a pure pale green, and their dimenſions not very unfrequently amount to ſeven or eight inches in length by two in diameter. At the very ſummit of the mountain is ſituated the third mine, in a vein of white indurated clay, mixed with arſenical pyrites: the beryls that it yields are generally of a greeniſh-blue colour, but ſometimes of a pure but pale ſky-blue, and very tranſparent.

Beryl is ranked by courteſy among the gems, but its value is greatly inferior to that of the emerald.

Emerald, *Oriental*, is a greeniſh variety of ſapphire.

Emerald, *Counterfeit*. The manner of making counterfeit emeralds in paſte is this: take cryſtal prepared, two ounces; common minium, or red lead, four ounces; mix theſe well together, then add of good verdegris two penny-weights, and crocus martis made with vinegar, eight grains. Mix all theſe well together, and ſet the whole in the hotteſt part of a potter's furnace, as long as the fire laſts. It muſt be put in a ſtrong crucible, and covered with a lute. When it is cold take off the lute, and, if it is baked enough, it will be clear to the bottom; otherwiſe relute the pot, and put it into the furnace again. Twenty-four hours commonly are ſufficient for making this; ſometimes it requires a little more. The paſte, thus made, is harder than ordinary, and is of a fine colour, and capable of a good poliſh. Neri's Art of Glaſs, p. 128.

If the paſte be deſired of a very deep emerald colour, take prepared cryſtal one ounce; red-lead, ſix ounces and a half; of verdegris, three penny-weights and thirteen grains; and of crocus martis, made with vinegar, ten grains. This requires a longer baking than the other, and is leſs hard, though of a deeper colour.

The proportions of theſe ingredients may be varied at pleaſure, and the colour be made of all degrees of deepneſs; but the more lead is added, the more baking is required, and, after all, the paſte will be ſo much the ſofter.

Emerald *Colour*, in the *Glaſs Trade*. The way of giving this beautiful dye to glaſs is this: in the pots of melted metal, made of polverine, and without manganeſe, when the matter is well purified, put a little crocus martis calcined with vinegar. About three ounces of this crocus is enough for a hundred weight of glaſs; let it ſtand till thoroughly mixed, then put into every hundred weight of metal two pounds of calcined braſs; this muſt be added at ſix different times, letting the metal ſtand two hours every time. When this is all in, make a proof of the metal; and if it has any blueiſhneſs, add more crocus martis, a ſmall quantity at a time. When the whole is of a fine leek-green, let it ſtand twenty-four hours to mix thoroughly, and then work it. Neri's Art of Glaſs, p. 51.

Emerald, or *Emeraud*, in *Heraldry*, is uſed in lieu of vert, or green, in blazoning the arms of dukes, earls, &c.

EMERGENT Year, in *Chronology*, is the epocha, or date, whence we begin to account our time.

Our emergent year is ſometimes the year of the creation; the Jews uſe that of the deluge, or the Exodus, &c. The emergent year of the Greeks was the eſtabliſhment, or at leaſt reſtoration, of the Olympic games by Iphitus. The Romans accounted their years from the building of the city, ab u. c. that is, ab urbe condita. See Epocha.

EMERITA Augusta, in *Ancient Geography*. See Augusta, and Merida.

EMERSA, Folia, in *Botany*, applies to ſuch leaves of aquatic plants as are raiſed above the ſurface of the water, and which are uſually of a different figure from thoſe that are *immerſa*, or ſunk under water. See Leaf.

EMERSION, in *Phyſics*, the riſing of any ſolid above the ſurface of a fluid ſpecifically heavier than itſelf, into which it had been violently immerged, or thruſt.

It is one of the known laws of hydroſtatics, that a lighter ſolid, being forced down into a heavier fluid, immediately endeavours to emerge; and that with a force, or moment, equal to the exceſs of a weight of a quantity of the fluid above that of an equal bulk of the ſolid.

Thus, if a ſolid be immerged in a fluid of double its ſpecific gravity, it will emerge again, till half its bulk, or body, be above the ſurface of the fluid.

Emersion, in *Aſtronomy*, is when the ſun, moon, or other planet, begins to re-appear, after its having been eclipſed, or hid by the interpoſition of the moon, earth, or other body.

The difference of longitude is ſometimes found by obſerving the immerſions and emerſions of the firſt of Jupiter's ſatellites.

The immerſions are obſerved from the time of Jupiter's being in conjunction with the ſun, to his oppoſition; and the emerſions, from the oppoſition to the conjunction; which two intervals are uſually ſix months a-piece, and divide the year between them.

But when Jupiter is in conjunction with the ſun, and fifteen days before and afterwards, there is nothing to be obſerved; the planet, with his ſatellites, being then loſt in the light of the ſun.

Emersion is alſo uſed when a ſtar, before hid by the ſun, as being too near him, begins to re-appear, and to get out of his rays.

Emersion, *Scruples*, or *Minutes of*, an arch of the moon's orbit, which the moon's centre paſſes over, from the time ſhe begins to emerge out of the ſhadow of the earth to the end of the eclipſe. See Eclipse.

EMERSON, William, in *Biography*, an eminent Engliſh mathematician, was born in 1701, at Hurworth, a village near Darlington, in the county of Durham. His father kept a ſchool, and was a good mathematical ſcholar: to him, and to a young clergyman, the ſubject of this article was chiefly indebted for his early inſtruction in the different branches of the mathematics. He attempted to keep a ſchool himſelf, but ſoon found his temper unfitted for the taſk; and, on the death of his parents, having come into the poſſeſſion of a moderate competence, he devoted himſelf to a life of ſtudious retirement, where he compoſed a great number of treatiſes, by which his name has been long known to all lovers of ſcience; and from the profits of which he redeemed his little patrimony from ſome incumbrances which he found on it. He enjoyed a good ſtate of health till nearly the cloſe of his life, when he had frequent and very ſevere attacks of the ſtone; a diſeaſe to which, in the year 1782, he fell a victim, when he had attained to the 81ſt year of his age. Mr. Emerſon was ſingular in his behaviour, dreſs, and converſation. His manners were rough, coarſe, and often very diſagreeable. In converſation, he was poſitive, dogmatical, and impatient of contradiction. His relaxation from ſtudy was ſometimes working in the fields, and ſometimes the amuſement of fiſhing, to which he was much attached. When he had any treatiſe for publication, he always went to London, to attend to the printing himſelf. He was an able mathematician; but his ſtyle as a writer is not adapted to ſmooth the path of ſcience for beginners. His works, which are very numerous, are now chiefly ſuperſeded by other and more popular writers, who have had the better art of facilitating the ſtudies of young perſons, by a more agreeable ſtyle, and an eaſier method of demonſtration. His "Treatiſe on Mechanics" is that which is now beſt known, and to which reference is more frequently made than to any of his other works.

EMERSTORFF, in *Geography*, a town of Germany, in the archduchy of Auſtria, ſeated on the Danube; 6 miles above Crems.

EMERUS, in *Botany*. See Coronilla, ſpecies 1.

EMERY, *Schmiergel*, Wern. in *Mineralogy*. Its colour is greyiſh-black or blueiſh-grey. It occurs maſſive and diſſeminated: when in maſs, it is generally encruſted with magnetic iron ore, pyrites, and mica; the latter ſubſtance frequently penetrates the whole maſs, giving it, when broken, a ſilvery appearance. It poſſeſſes a gliſtening or glimmering luſtre. Its fracture is fine-grained uneven, paſſing into ſplintery. In hardneſs it is about equal to Adamantine ſpar, cutting flint and rock-cryſtal with great eaſe. It is heavy, and not very eaſily frangible. When moſt free from iron, it conſiſts, according to Tennant, of

Silex	3.4
Alumine	92.
Iron	4.6
	100.

When highly impregnated with iron, this ingredient amounts to about 36 *per cent.*

Emery is procured from the iſlands of the Archipelago, eſpecially from Naxos; alſo from the neighbourhood of Alocer, in Eſtremadura, in Spain. Much of the emery uſed in France is imported from the iſlands of Guernſey and Jerſey, in the Britiſh channel. It is alſo found at Ochſenkopf, in Saxony, in beds of talc and ſteatite.

This mineral is largely uſed for cutting and poliſhing, by lapidaries and workers in glaſs and metal. The mode of its preparation is very ſimple. Being pulverized in an iron mortar, it is carefully waſhed over, and thus ſeparated into five or ſix different degrees of fineneſs, according to the work in which it is to be employed.

EMER-YAPAR, in *Geography*, a town of Aſia, in Thibet; 17 miles from Cha-tcheou.

EMESA, Emisa, *Emiſſa*, or *Emeſus*, in *Ancient Geography*, an ancient city of Syria, ſituated on the eaſtern bank of the Orontes, between Apamea and Laodicea Cabioſa. During the troubles which agitated Syria, this city was ſeized by an Arabian, named Sampſiceramus, who, aſſuming the title of king, held Emeſa and its ſmall territory, undiſturbed by the Seleucidæ, engaged in more important concerns. He left two ſons, Jamblichus and Alexander; the former of whom ſucceeded his father, and was much attached to the Romans. In the civil wars of Rome, he took part firſt with Cæſar againſt Pompey, and afterwards with Antony againſt Octavianus. After the victory gained by the latter at Actium, Antony, dreading his concurrence with other princes in favour of the conqueror, and upon this ſuſpicion, having got him into his power, cauſed him to be put to a moſt cruel death. Upon his death, Antony beſtowed the kingdom on his brother Alexander, who, continuing faithful to his benefactor in his greateſt diſtreſs, was taken priſoner by Octavianus, and not only deprived of his kingdom, but carried in triumph to Rome, and afterwards put to death. His ſon, Jamblichus II., was favoured by Octavianus, and reſtored by him to his father's kingdom, after he had remained for ſome time in a ſtate of exile. He had ſome ſucceſſors, who ſupported the dignity of this ſmall kingdom; but the laſt of its kings, whoſe name is recorded in hiſtory, was Azizus, who, falling in love with Druſilla, the ſiſter of Agrippa Minor, embraced the Jewiſh religion, in order to marry that princeſs. This ſmall kingdom was afterwards, as we may preſume, ſeized by the Arabians; for we find that, ſome years after, it was poſſeſſed by the Ituræans. Emeſa was the birth-place of the emperor Heliogabalus; and it was one of the cities in which the Romans planted colonies. It is now called *Homs;* and though formerly a ſtrong and populous city, it is at preſent only a large ruinous town in the pachalic of Damaſcus, containing not more than 2000 inhabitants, partly Greeks and partly Mahometans. An aga reſides here, who holds, as a ſub-renter of the pacha of Damaſcus, the whole country as far as Palmyra. The pacha himſelf holds this farm, as an appanage deriving immediately from the ſultan. Hama and Marra are held in the ſame manner; and theſe three farms pay 400 purſes, or 500,000 livres (about 20,000*l.*), but they produce nearly four times that ſum. Volney's Travels in Egypt and Syria, vol. ii.

EMETICS, in *Medicine*, from ἐμέω, *I vomit*, thoſe ſubſtances which excite vomiting, or cauſe the ſtomach to reject its contents upwards.

Medicines of this claſs have been employed, for the purpoſe of clearing the ſtomach, from the earlieſt ages to which any authentic records of practice extend. In the time of Hippocrates, indeed, the uſe of emetics ſeems to have been very general, not only as a remedy in diſeaſes of ſome ſeverity; but as a popular expedient for relieving ſlight indiſpoſition, eſpecially the occaſional derangements of the organs of digeſtion, brought on by indulgence in eating and drinking. Hippocrates even recommends them to the healthy as a preſervative; and he has ſtated many precepts with reſpect to the proper times for adminiſtering them, in conjunction or alternation with faſting, bathing, exerciſe, &c. under various circumſtances of health and diſeaſe. See his treatiſe on Diet, book iii. and elſewhere. Yet it muſt be remarked, that the catalogue of emetic ſubſtances in the poſſeſſion of the ancients was very imperfect, in compariſon with our own; and conſiſted either of uncertain and almoſt inert articles, on the one hand, or of ſevere and rather unmanageable ſubſtances on the other. Hippocrates preſcribed powdered hyſſop in about a gallon of water, as a vomit for corpulent men, with the addition of a little vinegar and ſalt; it was to be drank at firſt gradually, and afterwards more quickly.

Celſus has likewiſe detailed a ſet of rules, relative to the uſe of emetics, among the means of reducing the habit, if too plethoric. He ſays, "emetics are more uſeful in the winter than in the ſummer, becauſe in that ſeaſon there is more phlegm, and a greater heavineſs in the head. They are of no advantage to thoſe who are ſlender, or who have a weak ſtomach; but are uſeful to plethoric, and bilious people, whether they have ſuffered from repletion, or have their digeſtion impaired. For if they have taken more than the digeſtive power is able to concoct, they ought not to riſk the danger of its corrupting; and if it is already corrupted, it is proper to expel it in the moſt expeditious way poſſible. Hence, when any perſon is attacked with bitter eructations, together with pain and weight in the region of the ſtomach, let him immediately reſort to a vomit. It is alſo proper for thoſe, who have a ſenſe of heat in the breaſt, a frequent ſpitting or nauſea, or a noiſe in the ears, or humour in the eyes, or a bitterneſs in the mouth," &c. "I grant," he obſerves farther, "that emetics ſhould not be taken for the ſake of indulging a luxurious appetite; but that they are advantageous in ſome forms of diſeaſe, I know from experience: I admoniſh thoſe, however, who wiſh to enjoy good health and attain old age, not to make a daily uſe of them. If any one wiſhes to vomit after taking food, he ſhould firſt drink warm water only, if he vomits eaſily; if with ſome difficulty, he ſhould add a little ſalt or honey to the water: but he that intends to vomit in the morning, ſhould drink *mulſe* (a mixture of wine and honey,) or eat hyſſop, or radiſh, and then drink warm water, as has been already directed. All the other ſubſtances, which the ancient phyſicians preſcribed, are injurious to the ſtomach. If that organ is weak after the vomit, a little food ſhould be taken, of a proper kind; and if the fauces have been much irritated, three cups of cold water may be drunk. He who has uſed a vomit, if it were in the morning, ought to take a walk, then anoint, and afterwards ſup; but if after ſupper, he ſhould bathe on the following day, and ſweat in the bagnio: he will do well to make the next meal ſlight, and that of roaſted meat, with auſtere and unmixed wine, ſtale bread, and food of the drieſt kind." He concludes with this obſervation: "he that chuſes to vomit twice in the month, will find it more advantageous to do it for two days ſucceſſively, than if he were to repeat it on the fifteenth day; unleſs this intermiſſion ſhould occaſion a weight at his breaſt." De Medicinâ, lib. i. cap. 3.

Theſe ſtatements ſhew, that the uſe of emetics conſtituted a part of that regimen, among the ancients, in which more of their time was occupied, and more attention beſtowed, than the moderns in this country are accuſtomed to give to the ſubject. They alſo reſorted to vomiting, as a remedy in fevers, and other diſeaſes. See Celſus, lib. iii. cap. 7. And emetics, as well as purgatives, were employed after the termination of fevers, upon theoretical principles, to evacuate the remainder of the morbid matter, after its virulence was ſuppoſed to be ſubdued by concoction. In the uſe of purgatives, we find ſome remains of this theory among the people, as well as among the ignorant part of the profeſſion, even at the preſent day. Hippocrates ſeems to have believed, that this remnant of the morbid matter, like a piece of leaven, if retained after the criſis, was the occaſion of the return of the diſeaſe. "Quæ per morbos poſt judicationem intus relinquuntur, morborum reverſiones faciunt." Aphor. 12. ſect. ii.

The direct effect of an emetic is the evacuation of the contents of the ſtomach. Hence the principal purpoſe, for which it may be uſed, would ſeem to be the removal of morbid or noxious matters from that organ; whether conſiſting of its own ſecreted juices, in a diſeaſed condition of indigeſtible food, either from quantity or quality, of poiſons, or of other noxious ſubſtances, which may have been ſwallowed. Hence the vulgar reſort to emetics on every occaſion of what is popularly called a "foul ſtomach," or of "bile on the ſtomach." Theſe conditions are preſumed to exiſt, when ſuch ſymptoms as the following are preſent: when there is a want of the uſual appetite, or, in addition to that, a loathing of food; or, when, after food, or during the time of its digeſtion, an uneaſy ſenſation of fullneſs, weight, and diſtenſion is felt in the ſtomach, eſpecially if accompanied with heartburn, flatulency, and acid or bitter eructations; and to theſe may be added frequent head-achs, particularly in the morning.

Now, although it cannot be queſtioned, that the removal of the preſent contents of the ſtomach, in ſuch caſes, generally affords more or leſs relief; it is not the leſs certain, that this relief is ſeldom very durable; for the noxious matters are more frequently to be conſidered as the effects, than as the cauſes of the morbid condition of the ſtomach: they depend moſt commonly on the weakneſs and loſs of tone in the muſcular fibres of the ſtomach, and the imperfect ſecretion of the gaſtric juice; and theſe, it is obvious, are not to be cured by vomiting, though their conſequences may be relieved by this for a longer or ſhorter time. On the contrary, there can be no doubt, that frequent vomiting renders the ſtomach leſs able to retain, what is thrown into it, and to weaken its powers of digeſtion. "They are unhappy," ſays Dr. Cullen, "who truſt to this mode of relief, and have therefore frequent recourſe to it; for I am certain, from much experience, that frequent vomiting hurts the tone of the ſtomach, and often makes the ſymptoms of indigeſtion recur more frequently and ſooner than they otherwiſe would have done." Treatiſe on the Materia Medica, vol. ii. p. 465.

The ſame author remarks, that the effects of vomiting, and the degree of diſeaſe that required it, are commonly judged of by the vulgar, and often by phyſicians, though not always fairly, by the appearance of the matter thrown up. For example, there is commonly thrown up a conſiderable quantity of viſcid mucus; and to this the ſymptoms of the diſeaſe are frequently imputed. "It is, indeed, poſſible," he adds, "that an unuſual accumulation of mucus in the ſtomach may be the cauſe of want of appetite, and other ſymptoms of indigeſtion, but not always ſo juſtly as might be imagined. The mucous follicles of the ſtomach conſtantly pour out a conſiderable quantity of this matter; a conſiderable quantity is to be found in the ſtomachs of the moſt healthy perſons: and the experiments of M. Senac ſhew, that there is always a conſiderable quantity of it in the mucous follicles, which may very readily be ſqueezed out very copiouſly in vomiting. It is not, therefore, to be judged that the quantity, and even a large quantity, thrown up by vomiting, had either previouſly exiſted in the cavity of the ſtomach, or that ſuch a mucus had been the cauſe of the morbid ſymptoms, indicating therefore the repetition of vomiting. It has been upon occaſions of this practice, that I have known repeated vomiting, not only to give no durable relief, but rather to increaſe the ſuppoſed cauſe."

The evacuation, however, occaſioned by an emetic, is not confined excluſively to the ſtomach; the upper part of the inteſtines, namely, the *duodenum*, and even part of the *ilium*, is commonly evacuated at the ſame time. The periſtaltic motion of the alimentary canal may proceed either downwards or upwards; and when the action of any part of it is directed in one way, the next adjoining portion follows in ſome degree the ſame direction. Whence, in vomiting, as the periſtaltic motion of the ſtomach is directed upwards, ſo the motion of the duodenum, is directed in the ſame way, and it pours its contents into the ſtomach; from which it will appear that a conſiderable portion of the upper part of the inteſtines may be evacuated. The moſt clear proof of this inverted motion of the duodenum, in vomiting, is, that, eſpecially after repeated vomiting, a quantity of bile is poured into the ſtomach, and is in conſequence thrown out by the mouth. This frequent appearance may depend entirely upon the quantity of bile for the time preſent in the duodenum; but it probably extends farther. In the action of vomiting, as the contraction of the diaphragm and of the abdominal muſcles concurs at the ſame time, the whole viſcera of the abdomen are ſtrongly preſſed: this preſſure muſt affect the gall-bladder and the biliary ducts, and occaſion them to pour out their contents very largely, which, being thrown into the ſtomach from the *duodenum*, may be ejected by vomiting. It is commonly ſuppoſed, indeed, by the vulgar, that the bile thus thrown up exiſted previouſly in the ſtomach, and in ſome inſtances it may have been ſo: but it is more probable that it had been brought from the *duodenum*, and even from the gall-bladder and biliary ducts in the way juſt explained. For had the bile been previouſly lodged in the ſtomach itſelf, it might have appeared in the firſt vomitings, as well as in the laſt; but it happens, in almoſt all inſtances, that the bile is thrown out by the mouth only after repeated vomitings, and often after repeated ſtrainings in the organs employed in that act.

Dr. Cullen attributes ſome good effect to the preſſure on the liver and abdominal viſcera, juſt alluded to, in obviating the ſtagnations which are liable to occur in the ſyſtem of the *vena portarum*, and which lay the foundation of obſtinate diſeaſes. He affirms, that he knows no means of expediting the circulation in the liver ſo powerful as that of vomiting. Other writers have expreſſed an opinion of the advantages derived from this mechanical preſſure and conquaſſation of the viſcera of the abdomen, in exciting the meſenteric circulation, as well as that of all the glands, and conſequently in favouring and aiding all their ſecretions. (See Dr. Fothergill, De emeticorum uſu, &c. Cullen, loc. cit. p. 468.) Dr. Cullen, however, conſiders the effects of this mechanical compreſſion and motion as moſt evident in the viſcera of the thorax, eſpecially in promoting expectoration: hence the utility of vomiting in catarrhal affections, more particularly the chronic catarrh of old people. He alſo allows that it may be uſeful in many caſes of pulmonary conſumption; but juſtly adds, that we cannot, either from theory or experience, find any reaſon to believe that frequent vomiting is adequate to cure that diſeaſe.

There is alſo another indirect action of vomiting, which is beneficial to the ſyſtem, ariſing from the ſympathy between the ſtomach and the ſkin. This ſympathetic conſent between the veſſels of the ſkin and of the ſtomach is very great, inſomuch that the ſeveral ſtates of each may be communicated to thoſe of the other. Thus, wetting the ſkin relieves thirſt, as was proved by Capt. Bligh and his party; and in the ſame way the action of an emetic excites particularly the action of the veſſels on the ſurface of the body; and this action is excited by doſes of theſe medicines, which are not ſufficient to excite vomiting. Hence moſt of the ſubſtances employed as emetics are capable of exciting perſpiration. We are diſpoſed to believe that a ſimilar ſympathy, between the ſtomach and the veſſels in the cells of the lungs, is the cauſe of the utility of vomiting in producing expectoration, rather than the mere mechanical preſſure of the lungs.

The action of vomiting, when excited rather briſkly, by the general ſhock or conquaſſation of the whole frame, affects the nervous ſyſtem at large as a ſtimulant. In this way the utility of an emetic, in the commencement of a continued fever, is partly to be accounted for. Dr. Cullen, indeed, attributes the advantages of vomiting in that caſe to the relaxation of the ſpaſm of the extreme veſſels in the ſkin, according to his theory of fever; and partly, perhaps, the operation may be accounted for in this way: but it is to be remarked, that other expedients, which have nothing in common but the general ſhock which they occaſion to the nervous ſyſtem, alſo contribute to cut ſhort or to alleviate fever, under the ſame circumſtances; a briſk purgative, for example, cold affuſion, or the ſhower-bath, &c.

It is alſo obſerved by Dr. Fothergill, who aſcribes conſiderable effects to the *ſtimulant* operation of emetics, that, in ſpaſmodic diſorders, and ſeveral others of the nervous kind, which ſeem to ariſe principally from the torpor and languor of the digeſtive organs, emetics are often of eſſential benefit. He mentions CHOREA, or St. Vitus's Dance, certainly not the leaſt obſtinate of nervous complaints, as often relieved by emetics.

The ſame celebrated phyſician cautions us particularly reſpecting the adminiſtration of emetics to thoſe who are of plethoric habit, or who labour under diſeaſes, in which general or local plethora is preſent. If the ſymptoms, in ſuch caſes, indicate the propriety of employing emetics, blood-letting ought, in his opinion, to precede their uſe; for there is danger, leſt in the temporary convulſion of ſtraining to vomit, the diſtended veſſels ſhould be ruptured, or the blood be carried with too great force, or in too great quantity, to parts where the reſiſtance of the veſſels is too weak to withſtand it. Thus, if the veſſels of the head ſhould give way, a ſudden and fatal apoplexy may be brought on; if thoſe of the lungs ſhould be ruptured, a ſpitting of blood, followed by a ſlow, but not leſs fatal conſumption, may be induced, or ſimilar miſchief may be occaſioned in other viſcera. (Loc. citat.) In caſes, however, in which theſe plethoric diſeaſes are to be ſuſpected, the prudent practitioner will, even after blood letting, conſider emetics as inadmiſſible, unleſs the neceſſity of immediately emptying the ſtomach of its contents be great and preſſing.

The occaſion, on which ſuch a neceſſity is the moſt obviouſly paramount to all other conſiderations, is when poiſon has been recently ſwallowed. In this caſe, the greateſt riſk is from the operation of this ſubſtance on the ſtomach, and therefore the moſt expeditious means of inducing vomiting are to be adopted. If the poiſon be of the vegetable narcotic ſpecies, ſuch as opium, it often ſo completely paralyzes the muſcular fibres of the ſtomach, as that ordinary emetics have no power to excite its action. The white vitriol, or ſulphate of zinc, operates in general almoſt inſtantaneouſly, eſpecially if ſwallowed with a large quantity of water. When this has failed, we have known a few grains of the blue vitriol, or ſulphat of copper, diſſolved in warm water, given with ſucceſs, where opium had been ſwallowed. A ſtrong infuſion of ipecacuanha, drank copiouſly, has ſometimes effectually emptied the ſtomach under ſimilar circumſtances.

In a fit of inebriety, when vinous or fermented liquors have been drunk to the extent of inducing a ſtate approximating to apoplexy, the ſafeſt, perhaps, and beſt mode of emptying the poiſon from the ſtomach, conſiſts in pouring in warm water as copiouſly as it can be ſwallowed; ſince it at once dilutes the inebriating liquor in the ſtomach, and therefore diminiſhes its effects, and urges the ſtomach to expel it. See DRUNKENNESS.

Although emetics have been found to be beneficial in the early ſtages of all fevers, as already mentioned, yet we muſt not here omit to notice their peculiar good effects in the ſcarlet fever, as obſerved by Dr. Withering. (See his Treatiſe on the Scarlet Fever.) This fact, indeed, had been pointed out by Tournefort (in his voyage to the Levant, tom. i.), and other writers; but Dr. Withering recommends vomiting, repeated according to circumſtances, as the moſt eſſential remedy for this diſeaſe. "In the very firſt attack," he ſays, "a vomit ſeldom fails to remove the diſeaſe at once. If the poiſon has begun to exert its effects upon the nervous ſyſtem, emetics ſtop its further progreſs, and the patients quickly recover. If it has proceeded ſtill further, and occaſioned that amazing action in the capillaries, which exiſts when the ſcarlet colour of the ſkin takes place, vomiting never fails to procure a reſpite to the anxiety, the faintneſs, and delirium." Dr. Willan alſo ſpeaks highly of the utility of emetics in ſcarlet fever, with ſore throat, but has not found it neceſſary to repeat them ſo often as Dr. Withering adviſed. Treatiſe on Cutaneous Diſeaſes, ord. 3.

Emetics are ſometimes uſeful in aſthma, and in hooping-cough, probably upon the ſame principle as in chronic catarrh, before noticed. They have been ſaid alſo to aſſiſt in forwarding a gall-ſtone through the ducts into the inteſtines as well as an urinary calculus from the kidney to the bladder, through the ureter, by the mechanical agitation of the body, which they occaſion. But their operation in this way muſt be very feeble and uncertain, and may do injury, when the calculi are large or angular. Sydenham employed ſtrong emetics as remedies for dropſy; but they generally purged alſo, to which operation their good effects, when they did prove beneficial, muſt be the rather attributed.

The catalogue of medicines poſſeſſing an emetic power, which were in uſe among the ancients, although ſufficiently ample, contained, as we have already ſaid, ſubſtances either of feeble and uncertain action, or of acrid and violent qualities. The hellebore was ſometimes fatal. Even Sydenham complained in his time, that an emetic ſubſtance, which was "ſafe, and at the ſame time effectual," was a deſideratum in the Materia Medica. His active emetic conſiſted of the *crocus metallorum*, as it was then termed, or *crocus antimonii*, (a preparation made by deflagrating the ſulphurated antimony with an equal weight of nitre,) which being ſoluble in any acid, was moſt uncertain in its operation, as it depended upon the quantity of acid with which it met in the ſtomach. The ipecacuanha root appears to afford that ſubſtance to us, which was a deſideratum in the time of Sydenham.

We may, with Dr. Fothergill, conſider emetics under three heads, the very mild, the moderate, and the ſtrong or draſtic; not to mention the irritation of the throat with a feather; the exerciſe of ſwinging, ſailing, or whirling round certain objects of ſight, &c. which are not reſorted to as remedies. Among the mildeſt means of exciting vomiting, is filling the ſtomach ſuddenly with a large quantity of liquid; ſimple warm water is generally ſufficient for the purpoſe; but its operation is aided, when other ſubſtances of little power are combined with it: thus, infuſions of green tea, of chamomile flowers, the carduus benedictus, broths, &c. may be employed for this purpoſe. Again, when it might not be proper to give an emetic ſubſtance, in ſuch a doſe as might of itſelf excite vomiting, by the aſſiſtance of copious draughts of warm water, ſmall doſes may ſerve the purpoſe of evacuating the ſtomach, and even of obtaining the other effects to be derived from vomiting.

The moderately active emetic ſubſtances are thoſe which are at preſent in general uſe; namely, the ipecacuanha, and the tartar emetic, or tartrite of antimony, in ſmall doſes; and alſo ſome other ſubſtances, when much diluted with warm water, which might be of too inflammatory a nature if given alone, in ſuch quantity as to produce vomiting; ſuch are, an infuſion of the root of horſe-radiſh, or a tea-ſpoonful of muſtard as prepared for the table, ſome preparations of the ſquill, the aſarum, &c. The ipecacuanha was firſt introduced as a remedy for dyſentery; but it is now aſcertained that its utility in that diſeaſe depends upon its purgative quality.

The metallic ſalts formed with ſulphuric acid are active emetics, and may be arranged in the ſtrongeſt or draſtic claſs. The leaſt violent of theſe is the white vitriol, or ſulphate of zinc, which has been chiefly employed on account of the ſuddenneſs of its operation, when poiſonous matters have been taken into the ſtomach: but, in order to render its effects certain, the doſe muſt generally be large, and if it is not thrown out again immediately, it is apt to continue a diſagreeable nauſea, or even a vomiting, longer than is neceſſary. Dr. Cullen ſays, "I find that the purpoſe of this medicine (that is, a ſudden vomiting,) may commonly be obtained by employing a large doſe of ipecacuanha, either in powder or in the wine; and by following this ſoon after with a large draught of warm water impregnated with chamomile, or rather with what is more at hand, a tea-ſpoonful of table-muſtard; the buſineſs may be commonly very effectually executed."

The preparations of mercury are ſeldom employed as emetics. The ſulphat, or turpeth mineral, has been chiefly uſed, but its operation is violent.

Dr. Darwin obſerves, that "the quantity of the doſe of an emetic is not of ſo great conſequence as of other medicines, as the greateſt part of it is rejected with the firſt effort. All emetics are ſaid to act with greater certainty when given in a morning, if an opiate had been given the night before. For the ſenſorial power of irritation of the ſtomach had thus been in ſome meaſure previouſly exhauſted by the ſtimulus of the opium, which thus facilitates the action of the emetic; and which, when the doſe of opium has been large, is frequently followed on the next day by ſpontaneous ſickneſs and vomitings, as after violent intoxication." Zoonomia, part 3. art. v. 2. 1.

EMETIC *Powder,* called alſo *powder of Algaroth,* from the name of its author, is a precipitate of antimony; or butter of antimony ſweetened and ſoftened by repeated lotions. See ANTIMONY.

EMETIC *Tartar,* is now called *Antimonium Tartariſatum.* See ANTIMONY.

EMETIC *Wine, vinum antimonii,* is only white wine, wherein is infuſed ſome glaſs of antimony. See ANTIMONY.

Small doſes of emetic wine have been recommended as deobſtruent and ſudorific in ſlow fevers, in many chronical diſeaſes, and eſpecially in an obſtinate rheumatiſm. See Medic. Eſſ. Edinb. abr. vol. i. p. 170. and Huxham, Obſ. de Aere & Morb. epidem.

EMETZ, in *Geography,* a town of Ruſſian Siberia, in the government of Tobolſk; 28 miles W. of Iſchim.

EMEU, in *Ornithology,* the common name of the Caſſowary, a large bird of the oſtrich kind.

EMILE, in *Geography,* a ſmall town of France, in the department of the Seine and Oiſe, chief place of a canton in the diſtrict of Pontoiſe, with a population of 1800 individuals. The canton contains 20 communes and 13,843 inhabitants, on a territorial extent of $127\frac{1}{2}$ kiliometres.

EMILI, PAUL, in *Biography,* a modern hiſtorian, was born at Verona. In Italy he obtained a great character, and was brought into France by the cardinal de Bourbon, in 1487, who patronized him till his death. After this he was obliged to teach the languages for a ſubſiſtence. He undertook to write the hiſtory of France, for which he was rewarded with a canonry in the cathedral of Notre Dame. This hiſtory he brought down, in ten books, from Pharamond to the 5th year of Charles VIII.; it was publiſhed at different times; and likewiſe altogether at Paris in the year 1539, and has been ſeveral times re-printed and tranſlated into foreign languages. His ſtyle is pure, but ſometimes too conciſe, and even bordering on the obſcure; he is nevertheleſs to be regarded as the firſt writer who gave to French hiſtory a juſt form and method. He died at Paris in the year 1529, leaving behind him a very excellent character: his morals were as pure, as the language adopted in his works was chaſte and elegant. Bayle.

EMILION, SAINT, in *Geography,* a ſmall town of France, in the department of the Gironde, near the river Dordogne; ſix miles E. of Libourne, remarkable for the excellent wine which grows in its neighbourhood.

EMILIUS, ANTHONY, in *Biography,* profeſſor of hiſtory in the univerſity of Utrecht; was born Dec. 20th, 1589, at Aix la Chapelle, where his father had retired for the ſake of his religion. He received the early parts of his education in his native country, and finiſhed his claſſical ſtudies at Dort, under the famous Gerard John Voſſius: he then went to Leyden and other univerſities, and ſpent ſome years in foreign travel. On his return to his native country he ſucceeded Voſſius as rector of the college of Dort, and ſome time after he went to Utrecht to exerciſe the ſame office, where he was afterwards elected to the profeſſorſhip of hiſtory, an office in which he continued till his death, November 10th, 1660. His lectures, for more than twenty-ſix years, were taken from the annals of Tacitus. He publiſhed, about the year 1651, a collection of Latin ſpeeches and poems. Bayle.

EMILLAGUE, in *Geography,* one of the Pelew iſlands.

EMINENCE, a little hillock, or aſcent, above the level of the adjoining champain.

EMINENCE is alſo a title of honour given to cardinals.

The decree of the pope, whereby it is appointed, that the cardinals ſhould be addreſſed under the quality of eminence, bears date the 10th of January, 1630. They then laid aſide the titles of *illuſtriſſimi,* and *reverendiſſimi,* which they had before.

The grand maſter of Malta is likewiſe addreſſed under the quality of eminence.

The popes John VIII. and Gregory VII. gave the ſame title to the kings of France. The emperors have likewiſe borne it.

Eminentiſſimus, the ſuperlative of eminent, hath of late been attributed to the cardinals.

EMINENTIAL EQUATION is uſed by ſome algebraiſts in the inveſtigation of the areas of curvilinear figures; for a ſort of artificial equation, containing another equation eminently. Hayes Flux. p. 97.

EMINENTLY, EMINENTER, in the *Schools,* is uſed in contradiſtinction to *formally,* and in the ſame ſenſe with *virtually, viz.* to denote that a thing poſſeſſes, or contains, any other in a more perfect or higher manner than is required to a formal poſſeſſion thereof.

Thus an angel is ſaid to have prudence eminently; as he has it in a higher and more perfect degree than it is in man, in whom it is formally.

For one thing to contain another eminently, there are uſually required two conditions. 1. That the containing be of a more excellent nature than the contained. 2. That the leſs excellent be ſome way contained in the more excellent; *viz.* either as in its productive cauſe, or by ſome ſimilitude, or as to the manner and order of acting, &c.

EMIR, a title of dignity, or quality, among the Turks, and Saracens, attributed to ſuch as are relations or deſcendants of their great prophet Mahomet.

The word is Arabic, and literally ſignifies *prince.* It is formed of the verb אמר, *amar,* which is originally Hebrew; and in both theſe languages ſignifies *to ſay,* and *to command.* This is a title given to all the nobility of the firſt rank in the empire of the Mogul and in Tartary. The plural of this term is "Omra."

The emirs are held in high veneration, and have alone the privilege of wearing a green turban. On the borders of the Holy Land there are ſeveral emirs ſovereign princes; as the emir of Gaza, and the emir of Terabea, over whom the grand ſignior has but little authority. The title emir, at firſt, was only given to the caliphs: in Perſia they were alſo called *emir zadeh, q. d.* prince's ſon; whence by abbreviation of emir, they formed *mir;* and of *emir zadeh, mirza.* In after times, when the caliphs had aſſumed the title of ſultans, that of emir remained to their children, as that of Cæſar did among the Romans.

At length, the ſame title of emir came to be attributed to all who were judged to deſcend from Mahomet by his daughter Fatimah, and who wear the green turban.

Emir is alſo a title, which being joined to ſome other word, frequently denotes an office or employ; as the *emir al omera*, commander of commanders, who, in the time of the caliphs, was chief of the councils and armies.

The appellation emir is alſo applied by the Turks to all viziers and baſhaws, or governors of provinces. (See Bashaw, &c.) Add, that *emir akhor*, vulgarly *imrahor*, is maſter of the horſe to the grand ſeignior.

Emir alem, vulgarly *miralem*, ſtandard-bearer and director of all the ſtandards of the empire.

Emir bazar, the provoſt, or ſuperintendant of the markets, who regulates the prices of proviſions.

The *emir hagge*, or *hadj*, denoting pilgrimage, or prince conductor of the pilgrims of Egypt to Mecca, is baſhaw, or pacha of Damaſcus. See Caravan and Damascus.

Emir al moſleim, or *emir al moumenin*, *i. e.* commander of the faithful, or the believers, was a title aſſumed by the Almoravides and Almohades, who reigned in Africa and Spain.

Emir-*Bacha*, in *Geography*, a town of Aſiatic Turkey, in the province of Natolia; 80 miles W. of Tocat.

EMISSARIA, in *Anatomy*, are the veins which paſs into the ſkull from the external parts of the head, and terminate in the ſinuſes of the dura mater. Theſe openings are deſcribed in the article Cranium. The veins are ſometimes called after Santorini, an Italian anatomiſt. See Veins.

EMISSARIUM, in *Antiquity*, a ſluice, or drain, to draw off the water uſed in watering gardens, fields, &c.

EMISSARY, formed of *e* and *mitto*, *q. d.* I ſend out, a truſty, dextrous, able perſon, ſent ſecretly, to ſound the ſentiments and views of another, to make him ſome propoſal or overture; or to ſpread reports, watch the actions, motions, and countenance of a contrary party or perſon, in order to make advantage of them all. See Spy.

The leaders of parties have abundance of emiſſaries employed in their ſervice, who inform them of what paſſes every where, that they may take their meaſures accordingly.

EMISSION, the act of throwing, or driving a thing, particularly a fluid, from within, outwards. The ancients took viſion to be performed by the emiſſion of viſual rays from the eye.

But the term emiſſion is chiefly applied among us to the expulſion or ejaculation of the ſeed.

Emission *of Heat*.—All the heat we experience in the world is derived from three ſources; *viz.* from the ſun; from compreſſion, which comprehends colliſion and friction; and laſtly, from the decompoſition and compoſition of bodies.

It is hardly to be doubted, that the emanation of heat from the ſun, like the emanation of light from the ſame ſource, is not conſtantly the ſame; and it is recorded in hiſtory, that at certain times the light of the ſun has been obſerved to be pale, or leſs bright than uſual; and had the thermometer been in uſe amongſt the ancients, it would probably have been obſerved that the dimneſs of light was accompanied with a proportionate diminution of the uſual heat; for theſe alterations, as far as we can conjecture, ſeem to depend upon the ſize of the ſpots which cover the ſurface of the ſun at different and uncertain times.

The direct rays of the ſun on the ſame part of the ſurface of the earth, are more or leſs hot according to the time of the year, the clearneſs of the atmoſphere, the ſtate of the wind, and the colour or other quality of the ſpot upon which they fall. On this iſland, in the ſummer ſeaſon, the direct rays of the ſun ſeldom raiſe the thermometer to 110° But in other climates, eſpecially within the tropics, they raiſe it much higher; ſometimes as high as 150°. We muſt not, however, believe the ſtrange accounts of their melting lead or firing gun-powder; for thoſe rays cannot produce any ſuch effect, provided they are not concentrated, or aſſiſted, by artificial means.

It is not on account of the ſun's being nearer or farther from us, that we receive much more heat at one time of the year than at another; for the difference of its diſtance is too ſmall to produce any ſenſible effect; nor is it owing to the ſun's emitting more calorific rays at one time of the year than at another. But we receive more heat in ſummer than in winter, 1ſt, becauſe the ſun being nearer to our vertex, or to the zenith, in the former, than in the latter ſeaſon, its rays have a ſhorter way to paſs through the atmoſphere, and are of courſe leſs obſtructed by it. And the ſame cauſe renders the ſun's rays hotter about the middle, than at the commencement or the cloſe of the ſame day: 2dly, we receive more heat when the ſun is higher, becauſe in that caſe a greater quantity of its rays fall upon any given portion of the ſurface of the earth; than when it is lower, and its rays come in a direction more oblique; and, 3dly, becauſe in the ſummer ſeaſon the ſun remains longer above the horizon than in winter.

With reſpect to the cauſe of the emiſſion of heat from the body of the ſun, we cannot pretend to have the leaſt knowledge. It is generally ſuppoſed that the ſun is a body of fire; but it is impoſſible to ſay, whether it is an aggregate of caloric, independent of other matter, or a compound body undergoing a gradual decompoſition. It was, ſome time ago, alſo ſuppoſed, that the ſun emitted only rays of light, and that the action of thoſe rays upon terreſtrial bodies, extricated the heat from the latter. But the recent diſcovery (made by Dr. Herſchell,) of the calorific rays of the ſun ſuffering a different refraction from that of its luminous rays, beſides other conſiderations, renders this ſuppoſition vain. Excepting from the ſun, no ſenſible degree of heat is derived from the moon or from any other celeſtial object.

The immediate production of heat by the other means that have been mentioned above, *viz.* by compreſſion, colliſion, friction, compoſition and decompoſition of bodies, ariſes either from the caloric being ſqueezed out of a body, like water out of a ſpunge; or from an alteration of the capacities of bodies for containing heat. We ſhall endeavour to illuſtrate theſe proceſſes.

I. Experiments ſhew, that when a certain ſubſtance is compreſſed into a narrower ſpace, a quantity of heat comes out of it, and is communicated to the ſurrounding bodies. On the contrary, when a certain ſubſtance is expanded into a larger ſpace, it abſorbs a quantity of heat from the ſurrounding bodies; for theſe bodies are cooled in conſequence of it. Thus, if you wet your hand, and then expoſe it to the ambient air, the water, in the act of expanding itſelf into the form of vapour, abſorbs a quantity of heat from the hand, which is thereby ſenſibly cooled. If, by means of a condenſing engine, air is compreſſed in a proper veſſel, heat is extricated from it; and if the operation be performed quickly, a quantity of heat will be emitted, which is ſufficient to ſet fire to tinder, and other light combuſtible bodies. When the ſteam of water is condenſed, heat is depoſited by it upon thoſe bodies which are in contact with it.

Wood rubbed againſt wood, or againſt any hard body; metal rubbed againſt metal, or againſt any other hard body; in ſhort, ſolid bodies rubbed or knocked againſt each other, are thereby heated, often ſo far as to become red-hot.

By this means, heat may be produced where there is no oxygen, ſo that in thoſe caſes it cannot be derived from the decompoſition of that air. This has made ſome perſons ſuſpect that heat is not the effect of a peculiar ſubſtance called *caloric*; but that it is only a peculiar movement of the particles of bodies. The moſt ſtriking experiments relative to this ſubject were made by count Rumford (Phil. Tranſ. for 1798. p. 1.) He took a cannon, not yet bored, having a projection of two feet beyond its muzzle, a part which is uſually caſt with the piece, in order to inſure the ſolidity of the metal throughout, by the preſſure which its weight occaſions. This piece was reduced to the form of a cylinder, joined to the cannon by a ſmaller neck, and a large hole was bored in it: the whole cannon was then made to revolve on its axis by means of the force of horſes, while a blunt ſteel borer was preſſed againſt the bottom of the hollow cylinder, by a force equal to about 10,000lb. avoirdupoiſe; the ſurface of contact of the borer with the bottom of the cylinder being about two ſquare inches. This apparatus was wrapped up in flannel, when its temperature was about 60°. In half an hour, when the cylinder had made 960 turns, the horſes being ſtopped, a mercurial thermometer was introduced into a perforation in the bottom of the cylinder, extending from the ſide to the axis, and it ſtood at 130°, which count Rumford conſiders as expreſſing very nearly the mean temperature of the cylinder. The duſt or ſcales, abraded by the borer, weighed only 837 grains, or about $\frac{1}{950}$th of the whole weight of the cylinder. In another experiment, the cylinder was ſurrounded by a tight deal box, fitted with collars of leather, ſo as to allow it to revolve freely, and the interval between the cylinder and the box was filled with 19 pounds of cold water, which was excluded from the bore of the cylinder, by oiled leathers fixed on the borer; and after two hours and a half the water was made to boil. Hence count Rumford calculates that the heat produced in this manner, by the operation of friction, was equal to that of nine wax candles, each three quarters of an inch in diameter, continuing to burn for the ſame time.

Reaſoning upon theſe reſults, count Rumford thinks, that the heat, thus produced, cannot be extricated from the bodies concerned; and he is led to aſk "What is heat?—Is there any ſuch thing as an *igneous fluid?*—Is there any thing that can with propriety be called *caloric?*"

He then ſays, "We muſt not forget to conſider that moſt remarkable circumſtance, that the ſource of the heat generated by friction, in theſe experiments, appeared evidently to be *inexhauſtible.*

"It is hardly neceſſary to add, that any thing which any *inſulated* body, or ſyſtem of bodies, can continue to furniſh *without limitation*, cannot poſſibly be a *material ſubſtance:* and it appears to me to be extremely difficult, if not quite impoſſible, to form any diſtinct idea of any thing, capable of being excited, and communicated in theſe experiments, except it be *motion.*

"I am very far from pretending to know how, or by what means, or mechanical contrivance, that particular kind of motion in bodies, which has been ſuppoſed to conſtitute heat, is excited, continued, and propagated, and I ſhall not preſume to trouble the Royal Society with mere conjectures."

It muſt, however, be conſidered, that there is no friction which does not produce compreſſion; *viz.* a contraction of the bulk of the bodies concerned, at leaſt for a time; and therefore that the caloric is forced out of the bodies themſelves; and, being communicated to the ſurrounding bodies, produces the uſual ſigns of heat. It is a ſtrong corroboration of this aſſertion, that ſubſtances, which are not compreſſible, are not heated by mechanical force; thus, a flint will only be broken, but a piece of ſoft metal will be heated, by the ſtrokes of a hammer. Thus, alſo, you may place any weight upon a quantity of water, without altering its temperature, becauſe the compreſſibility of water is next to nothing; but if you place an additional weight upon a quantity of air; the bulk of the air will be contracted, and its temperature will be raiſed.

By about 15 or 20 ſmart and quick ſtrokes of a hammer on the end of a ſoft iron rod of about a quarter of an inch in diameter, placed upon an anvil, an expert blackſmith will render that end of the rod viſibly red-hot; and the ſofter the iron is, the quicker the effect will take place. But the production of vivid red ſparks from a piece of ſteel, when ſtruck againſt the edge of a flint, is a phenomenon not leſs curious. Theſe particles are ſcraped off by the flint, and are of courſe compreſſed ſo as to become red-hot.

"One of the moſt remarkable circumſtances, attending the production of heat by friction," ſays Dr. Young, "is the diſcovery of profeſſor Pictet, that it is often much more powerfully excited by ſoft ſubſtances than by harder ones. In making ſome experiments in a vacuum, in order to examine how far the preſence of air might be concerned in the effects of friction, he accidentally interpoſed ſome cotton between the bulb of his thermometer and the cup, which was ſubjected to the friction of various ſubſtances as it revolved; and he found that the ſoft filaments of the cotton excited much more heat, than any other of the ſubſtances employed."

II. When a body heated above the actual temperature of the atmoſphere, is placed amongſt other bodies, the ſuperfluous heat of the former is communicated to the latter; for there is no known body that can effectually intercept the tranſition of heat from one ſubſtance to another. But there is a remarkable phenomenon attending the communication of heat, which is neither very obvious, nor eaſily obſerved. This is, that in the diſtribution of heat amongſt a variety of ſubſtances, ſome bodies abſorb more of it than others, though they be all placed exactly in the ſame ſituation; hence different bodies are ſaid to have different *capacities* for abſorbing heat. (See HEAT, SPECIFIC HEAT, or SPECIFIC CALORIC.) So that if a certain quantity of heat is communicated to a mixture of equal weights of water and of mercury; the water will imbibe a much greater ſhare of that heat than the mercury, and yet both will appear of the ſame temperature.

Now it has been found that by mixing certain bodies together, their capacities for abſorbing heat is diminiſhed; therefore they part with a portion of their heat, which is of courſe communicated to the ſurrounding bodies. Thus, when a pint of ſpirit of wine is mixed with a pint of water, the mixture grows ſenſibly hot, becauſe their capacities for containing heat are diminiſhed in conſequence of their action upon each other. And it is to be remarked that whenever heat is emitted in the act of mixing fluids, as in the above-mentioned example of water and ſpirit, or of water and ſulphuric acid, &c. a concentration of bulk takes place; thus the above mixture of a pint of water with a pint of ſpirit will be found to meaſure leſs than two pints.

In combuſtions, the heat which is firſt communicated by the contact of an ignited body, or otherwiſe, decompoſes part of the combuſtible body, and of the ſurrounding oxygen air, which produces more heat, and this decompoſes more of thoſe bodies, and ſo the combuſtion proceeds and continues as long as there are combuſtibles and oxygen air ready for the proceſs. See EXCITATION *of heat.*

EMISSION *of Light.* The perception of objects, which we receive through our ſight, is obtained by the intermediation of ſomething, which we call *light*. Hence the blind muſt judge of the preſence of particular objects, by means of the ſound, or the ſmell, or the touch, &c. but not by the means of light. In ſhort, light does not ſenſibly affect any other part of our bodies, beſides the eyes. It follows then, that ſomething muſt paſs between any object we ſee and our eyes, but concerning this ſomething we have no certain knowledge. A variety of conjectures and hypotheſes have been offered; but of theſe hypotheſes two only may deſerve our attention. Deſcartes, Huyghens, and others, thought that a ſubtile fluid was diſperſed throughout the univerſe; that the luminous bodies, ſuch as the ſun, the ſtars, a lighted candle, &c. put that fluid, not in a progreſſive, but in a certain vibratory motion; (ſomewhat like the motion which is communicated to the air by ſonorous bodies;) and that this motion, being communicated to the nerves of our eyes, rendered the luminous objects perceptible to us. Newton and his followers ſuppoſe that light is a real emanation from luminous objects; *viz.* that a ſubtile fluid, conſiſting of certain peculiar particles of matter, proceeds from the luminous bodies; and by entering our eyes, excites in us the ſenſation of light, or the perception of luminous objects. A variety of facts and conſiderations ſeems to render this Newtonian hypotheſis of light by far the moſt probable of the two. See the article Light.

Admitting then Newton's hypotheſis, ſeveral conſequences, which naturally depend upon it, demand a particular illuſtration; *viz.* this emiſſion of light muſt conſiſt of particles; thoſe particles muſt have a very minute, but determinate, ſize;—they muſt be at certain diſtances from each other; muſt move with a certain velocity, and muſt have a certain momentum. Several remarkable diſcoveries that have been made in aſtronomy, and in other branches of natural philoſophy, enable us to determine the above-mentioned particulars, not with abſolute preciſion, but within certain limits of probabilty. The facts upon which this probability reſts, are as follows.

If a ſmall hole be made in a ſcreen, and the ſcreen be placed before our eyes, as about the diſtance of five or ſix feet; and if a luminous body, as a red-hot coal, be repeatedly paſſed before that hole, on the other ſide of the ſcreen, we muſt naturally perceive the hole luminous at intervals of time. But if the interval of time, during which the coal is not before the hole, be leſs than the tenth part of a ſecond, then the hole will appear conſtantly luminous, exactly as if the red-hot coal were held ſteadily before it. This ſhews that the impreſſion of light upon our eyes continues a certain time after the removal of the luminous objects. This is alſo the reaſon why, when a ſtick with a lighted extremity is quickly turned round in a circle before our eyes, we perceive an uninterrupted luminous circle.

The duration of the impreſſion of light upon our eyes is longer or ſhorter, according as the object is more or leſs luminous; ſo that the impreſſion is proportionally ſtrong. See the article Viſion.

Aſtronomers have obſerved, that the eclipſes of the ſatellites of Jupiter appear to take place ſooner than the time which is determined by the tables of their motions, when the planet is nearer to us; and later when that planet is farther from us. Hence it is naturally conjectured, that light moves progreſſively, and equally; *viz.* that it employs a certain time in going through a certain ſpace; and this conjecture is corroborated by other aſtronomical obſervations. The calculations, which have been made upon theſe appearances, ſhew that light moves at the aſtoniſhing rate of, at leaſt, 170,000 miles per ſecond; ſo that in its motion from the ſun to us, light employs about 8¼ minutes.

If a ſmall hole be made in a ſcreen, and ſeveral perſons are ſituated on one ſide of the ſcreen; every one of them looking through that hole at a different object placed on the other ſide of the ſcreen; it is evident that the various ſtreams of light from thoſe objects to the eyes of the obſervers, muſt paſs through the ſame ſmall hole in different directions, and without diſturbing each other, at leaſt in an obſervable degree. This ſhews, that the particles of light muſt be ſo very ſmall, and ſo diſtant from each other, as not ſenſibly to obſtruct each other's paſſage through a very narrow aperture.

In ſome experiments (rather imperfect) which were made by throwing the focus of a concave mirror upon the extremity of a very delicate beam, which was nicely ſuſpended, a ſlight motion was thereby communicated to the beam; whence it was deduced, that the light thus collected had a ſenſible momentum. From the weight of the beam, and from the motion which it had received from the impulſe of the light (upon the ſuppoſition that its motion was occaſioned by it); alſo from the above-mentioned velocity of light; it was calculated, that the quantity of matter, which was contained in the light which was thrown upon the end of that beam, during one ſecond of time, and which was collected from a reflecting ſurface of about four ſquare feet; amounted to no more than one twelve hundred millionth part of a grain. (Prieſtley's Hiſt. of Light, Viſion, &c. per. vi. ſect. i. chap. 3.) Theſe facts, joined to our daily experience, ſeem to authorize the following concluſions.

1. Since every phyſical point of a luminous object may be ſeen from every point of an immenſe ſpherical ſpace which ſurrounds it, when no opaque body is interpoſed, it follows, that the ſtreams of light, which proceed from all the points of viſible objects, and move in all manner of directions, are paſt all conception. If this be alleged as an objection to Newton's theory, the leaſt reflection will ſhew, that it offers an objection equally great, if not greater, to the other hypotheſis that has been mentioned above; but the following reaſoning will, in great meaſure, clear the difficulty with reſpect to Newton's hypotheſis.

2. It has been mentioned above, that the impreſſion of light remains a certain time upon our eyes, and (in the experiment with the red-hot charcoal) it has been ſhewn to remain about one-tenth part of a ſecond; but ſuppoſe it to remain only during the 100dth part of a ſecond. Then it is evident, that if 150 particles of light be emitted in a ſecond from a ſingle point of a luminous object, as from a point on the ſurface of the ſun; theſe particles will be more than ſufficient to give our eyes an uninterrupted viſion of that point; yet ſtill theſe particles, on account of their immenſe velocity, may be more than 1000 miles diſtant from one another, and, of courſe, may leave room enough for millions of other particles to paſs in all directions. Canton's Calcul. Ph. Tr. vol. 58.

3. The waſte of the ſubſtance of a luminous body, ariſing from the emiſſion of light, conſidering the minute nature of its particles, is very trifling, even with reſpect to the ſun, which has been the great fountain of light during ſo many centuries. Dr. Prieſtley, alluding to the above-mentioned experiment, where an impulſe was communicated to a beam by concentrated light, ſays, "Now the light in that experiment was collected from a ſurface of about four ſquare feet, which reflecting only about half what falls upon it, the quantity of matter contained in the rays of the ſun, incident upon a ſquare foot and half of ſurface, in one ſecond of time, ought to be no more than the twelve hundred millionth part of a grain. But the denſity of light at the

ſurface of the ſun is greater than at the earth in the proportion of 45,000 to 1; there ought, therefore, to iſſue from one ſquare foot of the ſun's ſurface in one ſecond of time, in order to ſupply the waſte by light, one-forty thouſandth part of a grain of matter; that is, a little more than two grains in a day, or about 4,752,000 grains, which is about 670 pounds avoirdupois, in 6000 years." Hiſt. of Light, &c. p. 390.

4. In conſequence of the motion of light, it is evident, that if a luminous body were ſuddenly placed in the heavens, at the ſame diſtance that the ſun is from us, we could not poſſibly ſee it before the lapſe of 8¼ minutes. Alſo, when we behold a celeſtial object, we do not ſee it exactly in the place where it actually ſtands; but we ſee it in the place where it ſtood ſome time before.

5. Light moves in ſtraight lines, as long as it goes through the ſame uniform medium, or through a vacuum.

6. When we direct our eyes towards certain poliſhed ſurfaces, we frequently ſee in them the appearances of objects, which are ſituated in places quite different from thoſe in which we ſee them. In this caſe the rays of light coming from thoſe objects fall upon the poliſhed ſurfaces, and from them they are *reflected* (that is, *ſent back*) to our eyes. Thoſe objects then are ſaid to be ſeen by reflected light, and the ſurfaces in which their appearances are ſeen are called the *reflecting ſurfaces*. Indeed, every body which does not itſelf emit any light, (as is the caſe with all thoſe which cannot be diſcerned in a dark room,) are ſeen by reflected light; for the light which is emitted from the ſun, from a candle, from a fire, &c. falls upon thoſe bodies, and is from them reflected to our eyes; but that light is reflected irregularly on account of the inequalities on the ſurfaces of moſt bodies; ſo that though all bodies which do not ſhine of themſelves, are ſeen by reflected light; yet they are called reflectors, or are ſaid to have reflecting ſurfaces, only when thoſe ſurfaces are ſmooth and poliſhed, in which caſe they reflect the light regularly, ſo as to repreſent the images of other objects, that are placed before them. See REFLECTION *of* LIGHT.

7. In its paſſage from one body into another, or from a vacuum into any ſubſtance, and *vice verſâ*, light is often bent in its direction; and that bending is called the *refraction of light*. See REFRACTION *of* LIGHT.

8. Light is likewiſe bent in its direction, when it paſſes cloſe by the ſurfaces of bodies; and this bending is called the *inflection of light*, which ſee.

The ſources of light are various, but they may be compriſed under the following enumeration.

1. The celeſtial bodies, which ſhine either by their own light, as the ſun and the ſtars; or by reflected light, like the moon and the ſatellites.

2. The *aurora borealis*, and other meteors, whoſe nature is not as yet diſtinctly known.

3. Bodies that are in a ſtate of *combuſtion*, and emit heat as well as light.

4. The *electrical light*; and,

5. The *phoſphoreſcent bodies*, of which there are ſeveral ſpecies, *viz.* 1. The *phoſphorus* properly ſo called, which is conſidered as an elementary ſubſtance. 2. The living animals which have the property of ſhining in the dark, ſuch as glow-worms, lantern-flies, &c. 3. Thoſe bodies which abſorb light when expoſed to it, and then emit it in the dark; ſuch are ſeveral precious ſtones, calcareous bodies, Canton's phoſphorus, the Bolonian ſtone after due preparation, &c. 4. The bodies which emit light when they are heated to a certain degree; fluoric ſtones, ſeveral marbles, calcareous earth, &c. have this property. 5. The ſubſtances which emit a light either quite white, or tinged with different ſhades of red or blue, by attrition; *viz.* by being rubbed or ſtruck againſt each other. Moſt ſtones of the ſilicious kind poſſeſs this property. 6. And laſtly; thoſe bodies which emit light without any ſenſible heat, whilſt they actually are under a ſtate of decompoſition; and of this ſort are moſt animal matters, and ſome vegetable ſubſtances, eſpecially rotten wood.

The doubtful nature of the *ignis fatuus*, or *jack-a-lantern*, may perhaps alſo be reckoned amongſt the phoſphori. See AURORA BOREALIS, ELECTRIC *light*, METEORS, PHOSPHORUS, PHOSPHORESCENT BODIES, and IGNIS FATUUS.

EMITES, in *Natural Hiſtory*, a name uſed by ſome authors for the chermites, a beautiful ſpecies of white marble, of which the tomb of Darius, and many other of the great works of antiquity, were made. It was valued for its fine poliſh.

EMLY, in *Geography*, a village of the county of Tipperary, province of Munſter, Ireland, the ſee of a biſhop; which was united to Caſhel in 1568. It is 15 miles W. from Caſhel.

EMLYN, THOMAS, in *Biography*, an eminent nonconformiſt divine, was born at Stamford, in the county of Lincoln, in the year 1663. His parents, though accuſtomed to attend the religious ſervice of the eſtabliſhed church, thought ſo favourably of the principles of the Proteſtant diſſenters, that they determined to educate their ſon for the miniſtry among perſons of this deſcription. Accordingly, he was placed for academical inſtruction in the year 1678, under the care of Mr. Shuttleworth, who reſided at Sulby, near Welford, in Northamptonſhire. In the following year he was admitted at Emanuel college, in the univerſity of Cambridge; but afterwards returned to Mr. Shuttleworth, under whoſe tuition he remained for four years. With a view to the enjoyment of ſuperior advantages, he removed, in 1682, to the academy of Mr. Doolittle in the vicinity of London, and in this ſituation he diligently availed himſelf of the collateral means and opportunities of improvement, afforded him by an acceſs to books, and intercourſe with literary perſons; and made ſuch improvement in the knowledge, connected with his profeſſion, that he was encouraged to commence the exerciſe of his profeſſion in December, 1682. His mind, at this early period, diſdained the ſhackles of eſtabliſhed ſyſtems of theology; and he determined to inquire freely, and to exerciſe, independently of the controul of authority, the right of private judgment. It was favourable to his future improvement, that he was not under a neceſſity of immediately connecting himſelf with a congregation, and of devoting his whole time to neceſſary preparation for the public ſervices of his profeſſion. In the year 1683, he became chaplain to the counteſs of Donegal, and accompanied her to Belfaſt in Ireland, where he had a liberal appointment, and was treated with reſpect and kindneſs. The counteſs married ſir William Franklin, a gentleman of conſiderable property in the weſt of England, who offered our young divine a valuable living in that country; but not approving the terms of miniſterial conformity, he declined the acceptance of it. His ſentiments, however, were ſo liberal, that he regularly attended the public ſervices of the eſtabliſhed church, and was himſelf attended in the evening, when he officiated in the counteſs's hall, by the miniſter of the pariſh, with whom he cultivated an intimate acquaintance. He likewiſe occaſionally officiated in the pariſh church, having obtained, without ſubſcription, a licence to preach from the biſhop of the dioceſe. At this time he viſited Dublin, and his ſervices were ſo acceptable to the congregation, of which Mr. Daniel Williams and Mr. Joſeph Boyce were paſtors, that he was afterwards induced to ſettle among them. In the mean while a variety of circumſtances occurred in the agitated ſtate of the north of Ireland, and the domeſtic diſunion of the family of his patroneſs, which rendered it expedient for Mr. Emlyn to remove to England. Accordingly in the year 1688, he came to London, where he renewed his acquaintance with Mr. (afterwards Dr.) Daniel Williams, who had relinquiſhed his paſtoral connection with the congregation at Dublin. As he paſſed to and fro from Ireland to London, he was accuſtomed to preach in ſeveral pariſh churches; and at Liverpool in particular, where he had accidentally officiated, his preaching was ſo much approved, that upon the deceaſe of the pariſh miniſter, whoſe place he had ſupplied, ſeveral of the inhabitants expreſſed their wiſhes, that they might be allowed to procure for him the living. But this offer, however reſpectful on their part, his principles would not permit him to accept. In 1689, Mr. Emlyn, being altogether unemployed, was invited by ſir Robert Rich, one of the lords of the admiralty, to his reſidence near Beccles in Suffolk; and he was induced to officiate to a diſſenting congregation at Loweſtoff, where he continued about a year and a half; though he declined complying with their invitation to undertake the paſtoral office. The liberality of his ſentiments and conduct, during his abode in this place, ſerved to promote a perfect harmony between the members of the eſtabliſhed church and the diſſenters. Here he became acquainted with Mr. William Manning, a reſpectable non-conformiſt miniſter in the neighbourhood; and their mutual intercourſe led them both to adopt ſentiments, with regard to the doctrine of the Trinity, in vindication of which Dr. Sherlock's treatiſe had juſt appeared, very different from thoſe which they had hitherto entertained. Mr. Manning became a Socinian; but Mr. Emlyn adopted what has been generally called the Arian opinion, believing the pre-exiſtence of our Saviour, as the Logos, and that by him God had created the material world. To this opinion he adhered through life. Upon the abdication of king James II., the turbulence of Ireland in ſome degree ſubſided; and Mr. Boyce urged Mr. Emlyn, to join him in the paſtoral care of the diſſenting congregation in Wood ſtreet, Dublin. After much previous deliberation, he accepted the propoſal, and, in 1691, removed to Dublin. Here he ſoon acquired diſtinguiſhed reputation as a preacher. His diſcourſes were rational, perſuaſive, and pathetic; his voice was clear and ſtrong, and his delivery dignified and graceful; the devotional ſervices were conducted with great propriety; controverſial ſubjects were avoided; and all the private duties of a Chriſtian paſtor were diſcharged in an exemplary manner. In 1694, Mr. Emlyn married Mrs. Eſther Bury, a widow lady, with a handſome jointure; and he was thus enabled to maintain a reſpectable appearance. After conſiderable heſitation and ſuſpence, he determined, when a proper occaſion offered, to avow his opinion concerning the doctrine of the Trinity. But before the formal execution of his purpoſe, he met with various domeſtic troubles. In 1701, he loſt both his ſon and his wife; the latter affliction deeply wounded his feeling, and led him to that admirable train of meditation, which is purſued in the funeral ſermon preached on the occaſion, and which was printed under the title of "Funeral Conſolations." Soon after he was bereaved of his wife, and whilſt his mind was in an unfit ſtate to encounter new conflicts, his opinion concerning the Trinity became the ſubject of inveſtigation. Dr. Cummins, a phyſician of Dublin, and a member of his congregation, communicated his ſuſpicions to Mr. Boyce; and they determined to apply to Mr. Emlyn for a declaration of his real ſentiments. Having explicitly avowed his opinion, that the God and father of Jeſus Chriſt is alone the Supreme Being, and that the ſon derives his excellence and authority from him, he offered to withdraw quietly from the congregation, and thus to prevent the diſturbance that was likely to enſue. But this pacific meaſure was unſatisfactory. Mr. Boyce, in a manner that reflects diſgrace on his memory, brought the matter before the Dublin miniſters, who, after a candid declaration of his ſentiments on the part of Mr. Emlyn, immediately forbade him to preach any more. His congregation, during this precipitate courſe of proceedings, was never conſulted on the occaſion. Mr. Emlyn avowed his ſentiments to the deacons and principal managers of the church; and after reſpectfully acknowledging their kindneſs to him, requeſted his diſmiſſion. The conduct of his accuſers was the cauſe of much ſurpriſe and concern to the congregation, and Dr. Cummins himſelf regretted the part which he had acted. However, it was at length determined that Mr. Emlyn ſhould retire for an interval to England; and ſuch was the violence of the Dublin miniſters, that, notwithſtanding the great inconvenience and expence, to which he was conſtrained to ſubmit, two of their number were deputed to "charge him not to preach any where when he went thither." Theſe perſecutors followed him with their letters of accuſation to London, and endeavoured to deprive him of the benefits of that candour and charity which he experienced on his arrival. Whilſt he remained in London, he publiſhed a ſhort account of his caſe; and after an abſence of 10 weeks, he reſolved to return to his family in Dublin. In order to obviate the prejudices that were entertained againſt his perſon and doctrine, he wrote his "Humble Inquiry into the Scripture account of Jeſus Chriſt, or a ſhort Argument concerning his Deity and Glory, according to the Goſpel." He then determined to return to England; but his purpoſe was prevented by the perſecuting ſpirit of his enemies, who obtained a ſpecial warrant from the lord chief juſtice to ſeize our author and his books. At firſt the chief juſtice refuſed bail; but afterwards allowed it, when two ſufficient perſons became bound in a recognizance of 800*l.* for Mr. Emlyn's perſonal appearance. In the next term the grand jury found a bill againſt him, in which he was indicted of blaſphemy. The trial came on in June 1703; and it was conducted in a manner no leſs diſgraceful and tyrannical than the proceedings of a board of popiſh inquiſitors. The jury were intimidated to deliver their verdict, and to bring in the defendant guilty, for which ſome of them afterwards expreſſed their concern. After the verdict was pronounced, the attorney-general moved, that the author might have the honour of the pillory; but ſentence was deferred till the laſt day of the term. In the mean time Mr. Emlyn was committed to the common gaol. Mr. Boyce now began to relent, and uſed all his intereſt to prevent the paſſing of the cruel ſentence threatened by the attorney-general. Mr. Emlyn alſo, in deference to the advice of his friends, wrote a letter to the lord chief juſtice, which was indited with a ſpirit, and in a ſtyle which ought to have influenced his mind. When he appeared to receive judgment, one of the queen's council moved that he ſhould retract; but Mr. Emlyn would not conſent. The lord chief juſtice, therefore, ſentenced him to ſuffer a year's impriſonment; to pay a fine of 1000*l.* to the queen, and to lie in priſon till it ſhould be paid; and to find ſecurity for his good behaviour during life. He was given to underſtand, that though the pillory was due to his crime, this puniſhment was not inflicted, as he was a man of letters. After ſentence was pronounced, he was led round the four courts with a paper on his breaſt, to be expoſed. For more than a quarter of a year, he was kept a cloſe priſoner in the under-ſheriff's houſe; and after the expiration of this term he was hurried away to the common gaol, where he lay among the priſoners in a cloſe room, filled with ſix beds, for about five or ſix weeks; and then he was removed upon his petition, by *habeas corpus*, to the Marſhalſea, on account of his health. In this priſon he wrote, in 1704, a treatiſe, entitled "General Remarks on Mr. Boyce's Vindication of the true Deity of our Bleſſed Saviour." In this ſtate of impriſonment, he remained until the month of July 1705, viſited by few of his former friends, and altogether neglected by his ſavage brethren, the Dublin miniſters. Mr. Boyce, indeed, ſhould be excepted; and to his zealous and repeated ſolicitations, to the generous interference of Thomas Medlicote, eſq., the humane interpoſition of the duke of Ormond, and the favourable report of the lord chancellor, that the exorbitant fine paſſed upon him was illegal, his releaſe from confinement was owing. By their exertions the fine was reduced to 70*l*., which was actually paid into her majeſty's exchequer; but the archbiſhop of Armagh, the queen's almoner, who had a claim of 1*s*. in the pound upon the whole fine, inſiſted on the whole ſum, nor would he extend his charity to a conſcientious ſufferer till he received 20*l*. by way of compoſition for the 50*l*. to which the ſentence entitled him. During Mr. Emlyn's confinement in the Marſhalſea, he conſtantly preached on ſundays to ſome of the impriſoned debtors, and ſeveral of the lower claſs of his former hearers. Soon after his releaſe Mr. Emlyn removed to London, where he preached once every ſunday to a ſmall congregation of perſons of ſentiments ſimilar to his own, but without receiving any ſalary. Attempts were made to reſtrain him by Charles Leſlie, the famous non-juror, and alſo by the lower houſe of convocation, but by the moderation of archbiſhop Teniſon, and the interference of government, they were unſucceſsful. Mr. Emlyn's congregation gradually declined by the death of his hearers, and was at length diſſolved; upon which he retired to obſcurity, and employed himſelf in vindicating, by various publications, the principles he had adopted, and the cauſe to which he was devoted. One of his moſt elaborate productions was entitled, "A Vindication of the Worſhip of the Lord Jeſus Chriſt, on Unitarian principles," and publiſhed in the year 1706. One of his moſt curious works was publiſhed in 1710, and was entitled "The Previous Queſtion to the ſeveral Queſtions about valid and invalid Baptiſm, lay Baptiſm, &c. conſidered, *viz*. whether there be any neceſſity, (upon the principles of Mr. Wall's Hiſtory of Infant Baptiſm) for the continual uſe of Baptiſm among the poſterity of baptiſed Chriſtians." In 1715, he publiſhed his "Full Enquiry into the original Authority of the Text, 1 John, v. 7, &c. containing an account of Dr. Mill's evidence from antiquity, for and againſt its being genuine, &c." In this controverſy there appeared, pro & con, ſeveral tracts, the titles of which we cannot recite in this place, nor can we mention the various publications of Mr. Emlyn on the ſubject of the Trinity. In 1719, he publiſhed "A true Narrative of the proceedings of the Diſſenting Miniſters of Dublin, againſt Mr. Thomas Emlyn, and of his Proſecution, (at ſome of the Diſſenters' Inſtigation,) in the ſecular court, &c." Mr. Emlyn, though himſelf unpopular, had the ſatisfaction to obſerve, that the opinion for which he ſuffered excited attention, and gained advocates, both in England and Ireland. Although none of the diſſenting miniſters in London could dare to aſk him to preach for them, except Mr. Burroughs, and Dr. James Foſter, he was honoured with the eſteem and friendſhip of many perſons, diſtinguiſhed by their ſtation and learning; and particularly by Dr. Samuel Clarke, and Mr. Whiſton. Upon the death of Mr. James Pierce of Exeter, about the year 1726, it was propoſed to invite Mr. Emlyn to be his ſucceſſor; but he wiſhed them to decline all thoughts of him, as his advanced age, and increaſing infirmities would not permit him to accept the office. The gout had much impaired Mr. Emlyn's conſtitution, and he at length fell a martyr to it, on the 30th of July, 1743, in the 79th year of his age. A complete collection of his works was made in 1746, and is compriſed in two vols. 8vo.; to which are added memoirs of his life, written by his ſon Sollom Emlyn. His ſermons are ſeparately publiſhed in one volume.

EMMA, in *Biography*, daughter of Richard II. duke of Normandy, wife of Ethelred king of England, and mother of Edward the Confeſſor, had a conſiderable ſhare of power during her ſon's reign. The duke of Kent, who was jealous of her great aſcendancy, and deſirous of getting rid of her as a rival, cauſed her to be accuſed of ſeveral high crimes, to which the king her ſon too readily liſtened, and not only deprived her of all thoſe immenſe treaſures which ſhe had amaſſed, but confined her for life in the monaſtery of Wincheſter. Some hiſtorians go much farther, and contend that ſhe was accuſed of murder, and of incontinence with the biſhop of Wincheſter, but Mr. Hume conſiders ſuch reports, and the ſtory of her being obliged to juſtify herſelf by walking over the nine red-hot plough-ſhares, as the inventions of Monks, and propagated for the ſake of exciting the ſilly wonder of poſterity. Bayle, however, gives full credit to the facts, and adds that the king, now ſenſible of the complete innocence of his mother, and penitent for the ſufferings he had inflicted on her, ſubmitted his back to the ſcourge. Hume. Bayle.

EMMAUS, in *Ancient Geography*, a village of Paleſtine, 60 furlongs N. of Jeruſalem; mentioned, Luke xxiv. 13, as the place whither two of our Lord's diſciples retired on the day of his reſurrection, and where he joined them in the form of a traveller, and demonſtrated to them, that the Meſſiah was to ſuffer death and to riſe again; and where he diſcovered himſelf to them at ſupper, while he was breaking bread. At this place were hot baths; and a church was erected on the ſpot where Cleopas, one of the fore-mentioned diſciples, ſtood. Joſephus informs us, that Veſpaſian left 800 ſoldiers in Judea, to whom he gave this village.

EMMAUS, a city of Judea, 22 miles from Lydda, afterwards called *Nicopolis*, and different from the village of Emmaus, though often confounded with it. Mr. Reland proves theſe to be different places from the teſtimonies of Joſephus, St. Jerom, the Maccabees, and the Talmudiſts. In this Emmaus, or Nicopolis, there were hot baths, in which, as the tradition of the inhabitants reports, our Lord waſhed his feet, and communicated a healing virtue to them. Julian, the apoſtate, from enmity to Chriſt, gave orders for ſtopping up this fountain.—Alſo, a town near Tiberias, in which were hot waters. Joſeph. de Bell. l. iv. c. 1.

EMME, in *Geography*. See EMMENTHAL.

EMMELIA, Εμμελεια, in *Antiquity*, a dance peculiar to tragedy, which had all the gravity and dignity that were ſuitable to the action then repreſenting, and was deſigned to inſpire the audience with ſentiments of compaſſion and benevolence for the unfortunate and oppreſſed, with indignation againſt the guilty, and with the love of virtue, and abhorrence of vice. The happy mixture of noble and elegant concords, together with an exquiſite modulation in the action of the perſonages, denoted by emmelia, is ſtrikingly exemplified in that piece of Æſchylus, in which king Priam offers a ranſom for the body of his ſon. The chorus of Trojans, proſtrate with him at the feet of the conqueror of Hector, and like him uttering, amid their dignified emotions, expreſſions of grief, fear, and hope, communicate to the ſoul of Achilles, and thoſe of the ſpectators, the ſentiments with which they are penetrated.

The movements of ſuch a dance as this muſt have been very ſolemn and majeſtic, and have bore a great affinity to the action of an orator; it was the only one, excepting the military dances, that had the approbation of Plato. Mem. Acad. Inſcript. vol. ii. p. 160. See Dance.

Emmelia, in *Muſic*, tuneful ſounds among the Greeks, ſuch as were fit for melody.

EMMELOORT, in *Geography*, a town in the north part of the iſland of Schockland, in the Zuyder ſea; 10 miles E. of Vollenhove.

EMMENAGOGUES, Menagoga, in *Medicine*, are ſuch ſubſtances as are underſtood to poſſeſs the power of exciting the menſtrual diſcharge in the female ſex.

Both the ancient and modern writers on the Materia Medica, but eſpecially the former, mention a great number of medicines, to which they attribute this power, and ſpeak of it with conſiderable confidence. But the articles, to which an emmenagogue quality has been thus aſcribed, have not ſucceeded in the hands of the phyſicians of cautious obſervation in our own times; ſo that it is now generally admitted, that we are not in poſſeſſion of a medicine, which has any ſpecific power in ſtimulating the veſſels of the uterus. Dr. Gregory aſks, in his Lectures, "What effect a medicine, poſſeſſed of ſuch a power, could have upon men?" which he ſeems to conſider as an unanſwerable refutation of the notion of emmenagogues. But may we not equally diſprove the exiſtence of a diuretic medicine, by inquiring what effect ſuch a medicine would produce in animals which have no kidney? Experience, however, amply corroborates the opinion; and the operation of thoſe ſubſtances, which have occaſioned the catamenia to flow, is explicable on other principles than that of a ſpecific ſtimulus to the uterine veſſels. But it is alſo to be remarked, that there is great room for deception with reſpect to the operation of medicines, in reſtoring or exciting the menſtrual diſcharge; and that the fallacious concluſion of "poſt hoc, ergo propter hoc," has given a character of efficacy to many medicines, (in all departments of practice, but in this moſt eminently,) which in truth poſſeſs no ſuch power. The catamenia frequently appear ſpontaneouſly, after long retention or ſuppreſſion; and whatever medicine happens to be under adminiſtration at that time gains the credit of the cure.

There is an error almoſt univerſally prevalent among the women themſelves, and ſanctioned by goſſiping medicaſters, that the ſuppreſſion of the menſes is the *cauſe* of almoſt every diſorder which the female conſtitution can ſuffer; and conſequently, that its reſtoration, in theſe caſes, is the moſt important point to be attended to in their treatment. Now the converſe of this poſition is much nearer the truth. The ſuppreſſion of the catamenia is moſt commonly the *effect* of a previouſly diſordered ſtate of the conſtitution, and will be removed, as a matter of courſe, when the health in general is reſtored. Hence, ſuch a ſuppreſſion is one of the ſymptoms of almoſt all chronic diſeaſes, and debilitated conditions of the body: it is ſometimes the conſequence of the oppoſite ſtate, of a plethoric or inflammatory diatheſis. The remedies, therefore, which poſſeſs an emmenagogue power, operate indirectly upon the uterine ſyſtem, through their effects upon the ſyſtem at large; and are conſequently of oppoſite qualities, as they apply to two oppoſite conditions of the conſtitution: or, they operate locally upon the adjoining parts, and affect the uterus from its contiguity.

The retention of the catamenia in young women, about the age of puberty, is generally connected with extreme debility of the ſyſtem, often with that morbid change of complexion which deſignates the green-ſickneſs, or Chlorosis, which ſee. It is in ſuch caſes, that preparations of iron, bark, and other tonic medicines, may be deemed emmenagogues, by reſtoring the general tone of the habit: the chalybeates have been particularly extolled for their emmenagogue powers. But in full florid habits, when the catamenia are ſuddenly ſuppreſſed, laxatives, diaphoretics, and even blood-letting, moſt effectually contribute to reſtore the diſcharge. Many other reputed emmenagogues operate as local ſtimuli to the contiguous parts: hence aloes, and other warm purgatives, which irritate the lower portion of the inteſtines, have been celebrated for their emmenagogue powers. Electricity, applied through the pelvis to the hips and back, has ſometimes been an efficacious emmenagogue. Savine, caſtor, the fœtid gums, the warm-bath, and pediluvium, may be deemed ſtimulants to the uterus, as a part of the general ſyſtem: the efficacy of the warm-bath, or ſlipper-bath, when employed about the expected period of menſtruation, is often very great. Dr. Mead highly extolled the tincture of black hellebore, which, he ſays, ſeldom failed in his practice; and he attributed to it ſuch a ſtimulative power over the blood-veſſels, that when it did not produce the menſes, he affirms, the blood was driven through other outlets, as from the noſe, bowels, &c. But Dr. Home, and many other phyſicians, have uſed it largely in vain. Dr. Home attributes ſome powers to the ſavine, and much to madder (rubia tinctorum); which, however, has appeared to others to be altogether inert. Cullen Mater. Medica, vol. ii. Home Clinical Exper. p. 377. See Amenorrhoea.

EMMENDINGEN, in *Geography*, a ſmall town of Germany, in the grand duchy of Baden Durlach, ſituated on the river Eltz, in the diſtrict of Hochberg, the neighbourhood of which produces excellent wine; but it is chiefly remarkable for a fruitleſs conference, which was held here in the year 1590, between the Roman Catholic and Lutheran divines of Germany. Emmendingen is on the high road from Switzerland to Francfort, on the Mayn.

EMMENTHAL, one of the fineſt and richeſt valleys of Switzerland, in the canton of Aarau, deriving its name from the river Emme, by which it is irrigated. The principal towns are Signau, Trachelwald, Soumiſwald, and Brandis. Its cheeſe is known all over Europe under the name of "fromage de Gruyères."

EMMERAN, Saint, formerly a rich imperial abbey of Germany, in the town of Ratiſbon. Its poſſeſſions form now a part of the territory of the prince primate of the Confederation of the Rhine.

EMMERICH, or Emmerick, a ſmall town of Germany, in the grand duchy of Berg, ſituated on the Rhine, in the former duchy of Cleves; 9 miles E. of the town of Cleves, and 24 miles S.E. of Nimeguen. N. lat. 51° 39′. It has a conſiderable trade with Holland, and was anciently one of the Hanſeatic towns. Its origin dates from the year 1247, when it was firſt ſurrounded with walls.

EMMIELLURE, in the *Manege*, a kind of compoſition of honey, and other ingredients, uſed for ſprains and ſhoulder-ſplaits of horſes. See Charge.

The word is French, derived from *miel*, honey, which is a part of the compoſition.

EMMIUS, Urbo, in *Biography*, a learned philologiſt and hiſtorian, was born in 1547, at Gretha, a village in

Eaſt Frieſland, of which his father was the paſtor. In his ſtudies he was diligent and remarkably ſucceſsful. His natural timidity and baſhfulneſs prevented him from undertaking the office of miniſter; and in 1579, he engaged as maſter of the ſchool of Norden, in Eaſt Frieſland, which he conducted with great reputation, till he was haraſſed by bigots for refuſing to ſubſcribe the confeſſion of Augſburg; and at length not only deprived of his ſalary, but prohibited from teaching. From Norden he went to Leer, where he undertook the ſame office, to the great injury of his late ſchool. When Groningen aſſociated itſelf with the United Provinces, and planned the re-eſtabliſhment of its college, Emmius was choſen its director, with the full power of forming ſuch ſtatutes for its government as he ſhould think proper. In this office he continued 20 years, when the college was erected into an univerſity; and Emmius was appointed profeſſor of hiſtory and Greek, in which he gave lectures to a very advanced period of life. He died at Groningen, in 1625, in the 79th year of his age, highly reſpected by all with whom he was connected; and his memory was ſo much honoured, that the magiſtrates, to whom he had been an able counſellor on all important occaſions, placed his portrait in the town-houſe. He publiſhed many valuable works on hiſtory, chronology, and antiquities: among theſe are, "Decades Rerum Friſicarum;" "Vetus Grecia illuſtrata," in three volumes, which is highly eſteemed as a valuable ſummary of the geography, hiſtory, polity, &c. of ancient Greece. It is recorded of him in his life, that he was ſo thoroughly verſed in the hiſtories of all kingdoms and countries, that, at the requeſt of his friends, he could at any time, and without previous conſideration, ſpeak upon the hiſtory of all kingdoms and countries, beginning with any period that might be fixed on, and give a complete detail of all the places, times, and circumſtances of perſons, as if he had come prepared expreſsly to explain thoſe hiſtories. Eulogies were pronounced on his memory by Thuanus, Scaliger, Douza, Heinſius, David Chytræus, and others. By Scaliger his hiſtory of Frieſland is called "divine." Bayle.

EMO, or Emo *Inn*, in *Geography*, in the Queen's county, province of Leinſter, Ireland, has been made a poſt-town, and is much frequented by travellers, as a convenient ſtage. Adjoining it is Emo-park, the ſeat of the earl of Portarlington. Emo is 35 miles S.W. from Dublin, and 5 E. from Maryborough.

EMODI Montes, or *Emodi Mons*, in *Ancient Geography*, part of a chain of mountains in Aſia. Pliny ſays, that the Emodus, the Imaus, the Paropamiſus, and the Caucaſus, were connected together; and that the Serres inhabited the country beyond theſe mountains. Dionyſius Periegetes places the ſprings of the Oxus in the Emodian mountains, and extends this chain as far as the Eaſtern ocean. The mountains Emodus and Imaus, according to major Rennell, are the mountains which extend from the Ganges, above Sirinagur, to Caſhmere: ſeparating the dependencies of Hindooſtan from thoſe of Great Thibet. This ingenious geographer ſuſpects Emodus and Imaus to be different readings of the ſame name; and Emaus or Himaus are, without doubt, derived from the Sanſcrit word *Himmaleh*, ſignifying ſnowy. That vaſt ridge bears the ſame name at preſent; and Pliny (l. vi.) well knew the circumſtance. The mountains of Rimola, ſo called in the Lama's map, to which the territories of Napaul extended, were anciently denominated Emodus; and they are a continuation of the chain between Taſſudon and Paridrong.

EMODIA, Αιμωδια, of αιμα, *blood*, and οδους, *tooth*, in *Medicine*, a word uſed by ſome authors to expreſs a ſtupor of the teeth.

EMOLLIENTS, are medicines which, when externally applied, have the power of relaxing or ſoftening the fibres, when too rigid. They have all been ſuppoſed to act mechanically, but this may be doubted. The commoneſt form of emollient is a cataplaſm or poultice of bread and milk, or other mucilaginous vegetable matter, applied to the ſkin as warm as can be borne without pain. The relaxation and conſequent eaſe which warm cataplaſms produce is very great; but as none of the materials can be readily abſorbed through the cuticle, when unbroken, the emollient effect has with great probability been attributed chiefly, if not entirely, to the relaxing effect of warmth and moiſture upon the extreme veſſels of the living ſurface, unconnected with any ſuppoſed interpoſition of moiſture between the moving fibres.

The other claſs of emollients comprehends unctuous bodies of all kinds, when aſſiſted by friction; and as there is no doubt of a conſiderable abſorption taking place in this method, it is not improbable that the fibres may be actually ſoftened, and rendered more flexible by mechanical operation. No comparative experiments have yet been fairly made to decide whether one unctuous body is more penetrating, that is to ſay, more readily abſorbed by the ſkin, than another; ſo that, as mere emollients, they all have equal claim to uſe.

EMOLUMENT, is properly applied to the profits ariſing daily from an office or employ.

The word is formed of the Latin *emolumentum*; which, according to ſome, primarily ſignifies the profits redounding to the miller from his mill; of *molo*, *molere*, *to grind*.

The patent, or other inſtrument, whereby a perſon is preferred to an office, gives him a right to enjoy all the dues, honours, profits, and emoluments, belonging thereto.

In our law-books, emolument is uſed in a ſomewhat greater latitude, for profit, or advantage, in the general.

EMOTION, in *Elocution*, a mode of utterance applied to appropriate paſſages and on proper occaſions, expreſſive of diſturbance and agitation in the mind of the ſpeaker, reader, or reciter, and calculated to produce the like diſturbance and agitation in the minds of the auditors. Under proper regulation of the judgment, this is one of the higheſt graces of elocutionary expreſſion; nay, ſo eminently is it calculated to produce the effects at which the higheſt ſpecies of elocution principally aim, that it may ſometimes be ſaid moſt completely to attain its end, when the judgment of the ſpeaker becomes for a while ſuſpended, or is at leaſt ſurrendered to its influence and domination. By ſome, however, it is diſputed whether the elocutioniſt (eſpecially the actor) ought really, (for the moſt perfect production of the effect deſired,) to be under the poſitive influence of the emotion exhibited, or ought only to imitate, by the ſtrong operation of judgment and recollection, ſo much of the actual emotion of real life, as appears calculated to excite the general or particular ſympathy deſired; and the writer of this article remembers an inſtance in which a public lecturer was much cenſured by a critical auditor, for having ſuffered himſelf to be overpowered by his own emotions, in deſcribing the tragical fate of Virginia, under the tyranny of the Roman decemviri, that the laſt ſyllable of the ſentence "he ſaved his honour, but he loſt his child," expired in an almoſt inarticulate ſob, and the orator, choaked with tears, was unable to proceed any farther. The effect produced was, however, the beſt anſwer to this hypercriticiſm. The orator had already proceeded far enough; for although one perſon remained cold enough to criticiſe, a ſhriek of horror had run through the audience, one half of whom had burſt into tears of ſympathy, and ſome of whom had actually ſwooned away, overpowered by contagious agitation. So ſuperior is nature and reality, to the boaſted mechaniſm of ſophiſtication and art. Art, however, and the ſevereſt exerciſe of judgment, are neceſſary both to the actor and the orator, (eſpecially to the latter,) in the direction and regulation of theſe emotions; that it may be known when, and how far they are to be indulged; the caſes being very rare in which it can be ſafe and proper to throw the reins on the neck of feeling, and leave it to make its way to the goal, by its own independent energies. Emotion is partly expreſſed by change of time or momentum, in the action of the organs of enunciation, and by different degrees of irregularity in the ſucceſſion and proportions of the cadences; and partly by the modulations of the voice; the intonations of which become modified by the different character of the paſſion to be expreſſed; while, in ſome inſtances, a tremulous expreſſion, and in others frequent interruptions and abrupt tranſitions in the tune, conſiderably heighten the effect. Two things are principally to be avoided in the purſuit or cultivation of this excellence;—the unreſtricted indulgence of ſuch feelings as might hurry into coarſeneſs, indecorous vehemence, or bombaſt; and that frigid affectation which aims at impreſſion by unnatural or unappropriate tones; extremes, which though they may extort *applauſe* from "the unſkilful," always diſguſt "the judicious," and diſappoint completely the legitimate end which genuine emotion muſt have in view,—the excitement of a correſpondent ſympathy.

Phyſiognomical expreſſion, or the play and ſympathy of the features, and the language of geſticulation, muſt not be overlooked: for, as Mr. Sheridan has obſerved, it is a palpable "deluſion," to ſuppoſe, "that by the help of words, alone, we can communicate all that paſſes in the mind of man. The paſſions and the fancy have a language of their own, utterly independent of words, by which only their exertions can be manifeſted and communicated." Lect. on Eloc.

In the recommendation of theſe accompaniments of elocution to any but the profeſſed actor, the profeſſor, however, muſt be aware that he has many and obſtinate prejudices to encounter. The dullneſs and indolence of modern elocutioniſts having conſpired, with other cauſes, to reduce almoſt all public ſpeaking, but that of the ſtage, to one ſympathetic monotony of tone, and look, and attitude, the ſuperſtition of criticiſm (miſtaking ſanction for propriety, and eſtabliſhed uſage for the law of nature) has raiſed a ſort of hue and cry, againſt all expreſſion of attitude and feature; as if theſe were mere theatrical affectations and meritricious artifices.

But this ſubject will be further purſued under the proper heads GESTICULATION and ORATORY; for the preſent it is only neceſſary to obſerve, that as eſſential to the perfection of that particular branch of the art, accompaniments of geſticulative and phyſiognomical emotion are univerſally admitted to be legitimate portions of the art of theatrical recitation, to the judicious application of which the elocution of the ſtage is indebted for a conſiderable part of its effect.

EMOTION, in the *Theory of the Mind*, is applied by Dr. Cogan (Treatiſe on the Paſſions) to the external marks, or viſible changes produced by the impetus of paſſion upon the corporeal ſyſtem. Thus he diſtinguiſhes it from paſſion, which denotes the violent impreſſion made upon our minds by the perception of ſomething very ſtriking and apparently intereſting, and from affections, which are applicable to the leſs violent, more deliberate, and more permanent impreſſions, by cauſes which appear ſufficiently intereſting. The ſtrong impreſſion, ſays this writer, of vivid ſenſation, immediately produces a re-action, correſpondent to its nature; either to appropriate and enjoy, or to avoid and repel the exciting cauſe. This re-action he diſtinguiſhes by the term *emotion*. The ſenſible effect produced at the firſt inſtant by the cauſe of the paſſion greatly agitates the frame; its influence is immediately communicated to the whole nervous ſyſtem, and the commotions excited in that, indicate themſelves both by attitudes and motions of the body, and particular expreſſions of the countenance. It is alone by theſe viſible effects, that the ſubject is diſcovered to be under the influence of any paſſion; and it is merely by the particular changes produced, or kind of emotion, that we are enabled to judge of the nature of the paſſion. Thus, although the paſſion exiſts prior to the emotions, yet as theſe are its external ſigns, they muſt indicate its continued influence as long as they continue to agitate the ſyſtem.

Sheridan, in his "Art of Reading," diſcriminates between ideas and emotions. The former, he ſays, denote all thoughts which riſe and paſs in ſucceſſion in the mind. Emotions ſignify all exertions of the mind in arranging, combining, and ſeparating its ideas, as well as all the effects produced on the mind itſelf by thoſe ideas, from the more violent agitation of the paſſions to the calmer feelings produced by the emotion of the intellect and the fancy. Thought is the object of the one, internal feeling of the other. That which ſerves to expreſs the former Sheridan calls the language of ideas; and the latter the language of emotions. Words are the ſigns of the one, tones of the other. Without the uſe of theſe two ſorts of language, it is impoſſible to communicate through the ear all that paſſes in the mind of man.

EMOY, or HIA-MEN, in *Geography*, an iſland near the S.E. coaſt of China, within the juriſdiction of the province of Fo-ken, about 15 miles in circumference. The port of Emoy is properly an anchoring-place for ſhips, incloſed on one ſide by the iſland from which it takes its name, and on the other by the main land; but it is ſo extenſive, as to be capable of containing ſeveral thouſand veſſels; and its water is ſo deep, that the largeſt ſhips may lie cloſe to the ſhore without danger. About a century ago it was much frequented by European veſſels; but few viſit it at preſent, as all the trade is carried on at Canton. The emperor keeps here a garriſon of ſix or ſeven thouſand men, commanded by a Chineſe general. At the mouth of the road is a large rock, viſible ſeveral feet above the ſurface of the water; and three leagues from it is a ſmall iſland, with a natural arch in the middle which admits light from the oppoſite ſide; and hence it obtained the name of the "Perforated iſland." The iſland of Emoy is particularly celebrated on account of the magnificence of its principal pagoda conſecrated to the deity "Fo." This temple is ſituated on a plain, terminated by the ſea on one ſide, and on the other by a lofty mountain. The front of the edifice is 180 feet in length, and its gate is adorned with figures in relief, the uſual ornaments of the Chineſe architecture. At the entrance is a large portico, with an altar in the middle, on which is placed a gigantic ſtatue of gilt braſs, repreſenting the god "Fo," ſitting croſs-legged. Four other ſtatues, 18 feet high, though repreſenting perſons ſitting, occupy the four corners of the portico. Each of them is formed from a ſingle block of ſtone, and bears in its hands appropriate ſymbols; *e. g.* one bears a ſerpent in its arms, twiſted round its body in ſeveral folds; another has a bent bow and quiver; the two others preſent, one a kind of battle-axe, and the other a guitar, or ſome ſimilar inſtrument. Beyond this portico is an outer court, having at its four ſides four pavilions, terminating in domes, and communicating with one another by a gallery. In one is a bell ten feet in diameter: in another a drum of enormous ſize, uſed by the bonzes for proclaiming the days of new and full moons. The two other pavilions contain the ornaments of the temple, and often ſerve to lodge travellers, whom the bonzes are obliged to receive. In the middle of the court is a large tower, terminating in a dome, with a beautiful ſtone ſtair-caſe winding round it. The dome contains a neat temple, the cieling of which is ornamented with moſaic work, and the walls covered with figures in relief, repreſenting animals and monſters. The pillars that ſupport the roof are framed of wood, varniſhed, and on feſtivals are ornamented with differently coloured flags. The pavement of the temple is formed of ſmall ſhells, preſenting in different compartments birds, butterflies, flowers, &c. The bonzes continually burn incenſe upon the altar, and keep the lamps ſuſpended from the cieling always lighted. At the extremity of the altar is a brazen urn, which, when ſtruck, emits a mournful ſound, and on the oppoſite ſide is a hollow machine of wood, uſed for the ſame purpoſe, which is to accompany with its ſound their voices, when they ſing in praiſe of the tutelary idol of the pagoda. The god "Pouſſa" is placed on the middle of this altar, on a flower of gilt braſs, which ſerves as a baſe, and holds a young child in his arms; ſeveral idols, which are without doubt ſubaltern deities, are ranged around him, and by their attitudes ſhew their reſpect and veneration. Behind the altar is a kind of library, containing books which treat of the worſhip of idols. Acroſs the court is a kind of gallery, containing 24 ſtatues of gilt braſs, repreſenting philoſophers, who were the ancient diſciples of Confucius. At the end of the gallery is a hall, which is the refectory of the bonzes; and beyond a ſpacious apartment is the temple of "Fo," to which there is an aſcent by a large ſtone ſtair-caſe. This temple is ornamented with vaſes, full of artificial flowers, and in it are muſical inſtruments, ſuch as we have already mentioned. The ſtatue of this god is ſeen through a piece of black gauze, which forms a ſort of veil or curtain before the altar. The reſt of the pagoda conſiſts of ſeveral large chambers; the gardens and pleaſure-grounds are on the declivity of the mountain, and a number of delightful grottos are cut out in the rock, and afford an agreeable ſhelter from the exceſſive heat of the ſun. There are ſeveral other pagodas in the iſland of Emoy; one of which is called the "Pagoda of 10,000 ſtones," which is built on the brow of a mountain, in which there is a like number of little rocks, under which the bonzes have formed grottos and pleaſant covered ſeats. Groſier's China, vol. i.

EMPALEMENT, or Impalement, a cruel kind of puniſhment, whereby a ſharp pale or ſtake, is thruſt up the fundament and through the body.

The word comes from the French, *empaler*, or the Italian, *impalare;* or rather, they are all alike derived from the Latin, *palus*, *a ſtake*, and the prepoſition *in*, *in*, *into*.

We find mention of empaling in Juvenal. It was frequently practiſed in the time of Nero, and continues to be ſo in Turkey.

Empalement, or *Calyx*, in *Botany*, denotes the termination of the cortex, or outer bark of a plant; which, after accompanying the trunk or ſtem through all its branches, breaks out with the flower, and is preſent in the fructification in this new form. Its chief uſe is to encloſe and protect the other parts. It has received different appellations, according to the circumſtances that attend it; as *Perianthium*, or flower-cup, *Involucrum*, or cover, *Amentum*, or catkin, *Spatha*, or ſheath, *Glume*, or huſk, *Calyptra*, or veil, and *Volva*, which ſee reſpectively. See Calyx.

EMPANELLING, or Impanelling, in *Law*, ſignifies the writing and entering into a parchment ſchedule, or roll of paper, by the ſheriff, the names of a jury ſummoned by him to appear for the performance of ſuch public ſervice as juries are employed in. See Jury.

EMPARLANCE, or Imparlance, *Interlocutio*, or *licentia loquendi*, in *Law*, a deſire, or petition, in court, of a day to conſider, or adviſe, what anſwer the defendant ſhall make to the action of the plaintiff.

The civilians call it *petitio induciarum*. Kitchen mentions emparlance *general*, and *ſpecial;* the firſt ſeems to be only that made in one word, or in general terms without any ſpecial clauſe. This is of courſe where the defendant is not bound to plead the ſame term; and it is without ſaving to the defendant any exception, which is always to another term. It is granted to the defendant before he pleads by conſent of the court; to ſee if he can end the matter amicably without farther ſuit, by talking with the plaintiff:—a practice, which is ſuppoſed (Gilb. Hiſt. Com. Pl. 55.) to have ariſen from a principle of religion in obedience to that precept of the goſpel "agree with thine adverſary quickly, whilſt thou art *in the way* with him." (Matt. v. 25.) It may be obſerved, that this goſpel precept has a plain reference to the Roman law of the twelve tables, which expreſsly directed the plaintiff and defendant to make up the matter while they were *in the way*, or going to the prætor;—*in via, rem uti pacant orato*. Emparlance *ſpecial*, is where the party requires a day to deliberate, adding theſe words, "Salvis omnibus advantagiis tam ad juriſdictionem curiæ, quam ad breve et narrationem."

This emparlance is had on the declaration of the plaintiff; and it is of uſe where the defendant is to plead ſome matters, which cannot be pleaded after a general emparlance. (5 Rep. 75.) This ſpecial emparlance is with a ſaving of all exceptions to the writ or count which may be granted by the prothonotary; or they may be ſtill *more ſpecial*, with a ſaving of all exceptions whatſoever, which are granted at the diſcretion of the court. (12 Mod. 529.)

Imparlance is generally to the next term; and if the plaintiff amend his declaration after delivered or filed, the defendant may imparl to the next term, if the plaintiff do not pay coſts, but if he pay coſts, which are accepted, the defendant cannot imparl. Alſo, if the plaintiff declares againſt the defendant, but doth not proceed in three terms after, the defendant may imparl to the next term. (2 Lill. Abr. 35.) If the writ be returnable on the laſt day of term, the defendant is of courſe entitled to an imparlance, but muſt plead in four days of the next term, provided a rule be given either in a town or country cauſe. On a declaration delivered of *Hilary*, there may be an imparlance to *Trinity* term, if the defendant has not pleaded before; for it is the courſe of the court to give imparlance or declaration till the day of pleading. If a writ be returnable in one term, and the declaration is not delivered *before* the eſſoign day of the *ſecond* term, the defendant is not obliged to plead in the *ſame* term, but is entitled to an imparlance. (Impey, K. B.) The cauſes of imparlance are as follow. The not delivering a declaration in time is ſometimes the cauſe of imparlance of courſe, and where the defendant's caſe requires a ſpecial plea, and the matter which is to be pleaded is difficult, the court will, upon motion, grant the defendant an imparlance, and longer time to put in his plea, than otherwiſe by the rules of the court he ought to have: if the plaintiff keeps any deed or other thing from the defendant, whereby he is to make his defence, imparlance may be granted till the plaintiff delivers it to him, or brings it into court, and a convenient time after to plead. (Hil. 22 Car. I. B. R.) There are many caſes in which imparlances are not allowed. No imparlance is granted in an *homine replegiando;* or in an aſſiſe, unleſs on good cauſe ſhewn; nor ſhall there be an imparlance in an action of ſpecial *clauſum fregit,* though it is allowed in general actions of treſpaſs. (Hil. 9 W. III. 3 Salk. 186.) Where an attorney, or other privileged perſon of the court ſues another, the defendant cannot imparl, but muſt plead preſently: if the plaintiff ſues out a ſpecial original, wherein the cauſe of action is expreſſed, and the defendant is taken on a ſpecial capias, he ſhall not have imparlance, but ſhall plead as ſoon as the rules are out. (2 Lil. 35, 36.) In caſe of pleadings afterwards, a plea to the juriſdiction may not be pleaded after general imparlance. (Raym. 34.) Dilatory pleas cannot be pleaded after a general imparlance, which is an acknowledgment of the propriety of the action. After imparlance the defendant cannot plead in *abatement;* however, if it appear by the record that the plaintiff hath brought his action before he had any cauſe, the court *ex officio* will abate the writ. (2 Lev. 197.) Although a ſpecial imparlance ſhall not be allowed the defendant without leave of the court firſt obtained (R. E. 5 Ann.); yet if the writ be returnable *before the laſt return of any term,* and the declaration not filed, and notice given four days excluſive before the end of ſuch term, the defendant is entitled to an imparlance, (R. Trin. 22 Geo. III.) Blackſt. Com. vol. iii. Jacob's Law Dict. by Tomlins. Art. *Emparlance.*

Britton alſo uſes emparlance for the conference of a jury upon a cauſe committed to them.

EMPASMA, Εμπασμα, from εμπὰσσο; *I ſprinkle,* in *Pharmacy,* a powder thrown or ſprinkled over the body, to correct ſome ill ſmell thereof, or to prevent unneceſſary ſweats.

EMPASTING, or IMPASTING, a term uſed in *Painting,* for the laying on of colours thick and bold, or applying ſeveral lays of colours, ſo that they may appear thick. See COLOURING.

It is formed of the French, *empaſter,* which has the ſame ſignification of *paſte,* or *pâte, paſte.*

A painting is ſaid to be well empaſted with colours, when the colours are beſtowed plentifully, or it is well ſoaked, and ſaturated with colours.

The term is alſo uſed when the colours are laid diſtinct, and aſunder, and not ſoftened and loſt in each other: *e. g.* this head is not painted, it is only empaſted.

EMPATTEMENT, French, from *empater, to thicken,* in *Fortification,* a term uſed by ſome to denote the ſame with talus.

EMPEDOCLES, in *Biography,* a native of Agrigentum, in Sicily, was a diſciple of Telauges, a ſcholar of Pythagoras, and diſtinguiſhed for his knowledge in every department of ſcience and philoſophy, as a poet, an orator, an hiſtorian, and a phyſician. He adopted the Pythagorean doctrine of the tranſmigration of ſouls, and wrote a poem on the ſubject, which the ancients have highly praiſed. He ſtated the hiſtory of the different changes which his own ſoul had undergone during its tranſmigrations, as follows; it commenced its career in the perſon of a girl, next appeared in that of a boy, afterwards it animated a ſhrub, then a bird, a fiſh, and laſtly Empedocles. In the ſame poem, the title of which was, "On the Nature of Things," he explained his doctrine reſpecting the elements. He contended that "there were four of theſe elements, which are at continual war with each other, without the power of deſtroying each other; and that all bodies were produced by this conflict." The fragments of his verſes, which are diſperſed through various ancient writers, have been, in part, collected by Henry Stephens. (In Poeſi Phil. 1574, 8vo.) This circumſtance affords ſome ground for the opinion of Fabricius, (Bib. Græc. v. i. p. 466.) that Empedocles was the real author of that ancient fragment, which bears the title of "The golden Verſes of Pythagoras." From theſe fragments his philoſophical opinions have been collected. Beſides his hypotheſis of four elements, the firſt material principles of which were indefinitely ſmall, round, and ſimilar atoms, he maintained, that it is impoſſible to judge of truth by the ſenſes without the aſſiſtance of reaſon; which is led, by the intervention of the ſenſes, to the contemplation of the real nature, and immutable eſſences, of things. The firſt principles of nature are of two kinds, active and paſſive; the active is unity, or God; the paſſive, matter. The active principle is a ſubtle, ethereal fire, intelligent and divine, which gives being to all things, and animates all things, and into which all things will be at laſt reſolved. Many dæmons, portions of the divine nature, wander through the region of the air, and adminiſter human affairs. Man, and alſo all brute animals, are allied to the divinity; and it is therefore unlawful to kill or eat animals. The world is one whole, circumſcribed by the revolution of the ſun, and ſurrounded, not by a vacuum, but by a maſs of inactive matter. In the formation of the world, ether was firſt ſecreted from chaos, then fire, then earth; by the agitation of which were produced water and air. The heavens are a ſolid body of air, cryſtallized by fire. The ſtars are bodies compoſed of fire, they are fixed in the cryſtal of heaven; but the planets wander freely beneath it. The ſun is a fiery maſs, larger than the moon, which is in the form of a hollow plate, and twice as far from the ſun as from the earth. The ſoul of man conſiſts of two parts, the ſenſitive, produced from the ſame principles with the elements; and the rational, which is a dæmon ſprung from the divine ſoul of the world, and ſent down into the body as a puniſhment for its crimes in a former ſtate, where it tranſmigrates till it is ſufficiently purified to return to God.

The ſtyle of Empedocles, if we may believe the account of Ariſtotle, as quoted by Diogenes Laertius, very much reſembled that of Homer; it was extremely energetic and enriched with metaphor, and every variety of poetical figure. His talents drew upon him the eyes of all Greece: his verſes were ſung at the Olympic games, with thoſe of Homer, Heſiod, and the moſt famous poets; and at the games, and on all other public occaſions, he is ſaid to have been himſelf the moſt attractive part of the ſpectacle, ſo anxious were the people to behold him. He was greatly diſtinguiſhed too as an orator, and is ſaid to have been the firſt of the philoſophers who gave leſſons on rhetoric in Sicily. He uſefully employed this talent of oratory in reforming the licentious manners of the Agrigentines, whom he reproached "for purſuing pleaſures, with as much eagerneſs as if they were to die before to-morrow; and for building houſes as if they believed that they ſhould live for ever."

Empedocles was likewiſe celebrated as a phyſician, and wrote a poem "On Medicine," conſiſting of ſix hundred verſes. In this work he is ſaid to have boaſted, that he was able not only to cure diſeaſes, but alſo to drive away old age, and even to reſtore the dead to life; and to have intimated that the ſick would hereafter inveſt him with divine honours. Pliny affirms that he ſucceeded in reſtoring a female, who had lain thirty days, without any ſigns of reſpiration: and

Pauſanias, one of his diſciples, and a phyſician, wrote a treatiſe reſpecting the diſeaſe and recovery of this woman, whom he termed ἄπνους. He was greatly ſkilled in muſic, which, after the example of Pythagoras, he employed as a remedy, not only againſt the diſeaſes of the mind, but even againſt thoſe of the body. Being lodged in the town of Gela, with his friend Auchitus, he was informed that a young man in a great rage was determined to kill this friend, who had ſentenced his father to capital puniſhment. Empedocles endeavoured to calm his mind by perſuaſive diſcourſe; but his eloquence producing no effect, he took his lyre, and combined its melodious ſounds with the flowing numbers of poetry; and ſo employed the modulations, which made the greateſt impreſſion on the heart of the young man, that by degrees he was entirely ſoftened, and afterwards became his conſtant diſciple. As a phyſician, he is related to have been eminently ſerviceable to his country on many occaſions. He paid great attention to meteorology, and not only predicted ſtorms, but propoſed remedies againſt their effects. He counteracted the blighting influence of the Eteſian winds, by conſtructing walls in the narrow paſſages of the mountains, through which they blew, and occaſioned ſterility in the neighbouring land: hence, according to Jamblichus and Diogenes Laërtius, he was called *Alexanemos* and *Colyſanemos*, or repeller of the winds. Pliny relates that he allayed a peſtilence at Agrigentum, by means of fumigation (ignium ſuffitu); and Plutarch mentions another inſtance, in which he ſuppreſſed a plague, which raged with extreme violence and fatality, by cloſing an aperture or chaſm of the earth, in the vicinity of the mountains, from which he alone obſerved that peſtilential effluvia iſſued.

For theſe various ſervices to his country, the Agrigentines offered him the government; which he refuſed, preferring a philoſophical tranquillity to regal honours. He is ſaid, by ſome of his hiſtorians, to have been ever generous, humane, and moderate, and ready at all times to ſtand forth as the declared enemy of tyrants; and to have vigorouſly purſued all thoſe who ſeemed to aſpire at the ſovereign power. An anecdote is handed down to us in confirmation of this fact. A citizen of Agrigentum having invited him home to ſupper, and the hour of the repaſt being arrived, he inquired why it was not ſerved up; "becauſe," ſaid the hoſt, "we wait for the miniſter of the council." At length this officer appeared, and he was made maſter of the feaſt; during which he gave himſelf ſo many inſolent airs, that Empedocles began to ſuſpect that ſome ſecret project was concerted between the maſter of the feaſt and his inviter, with a view to re-eſtabliſh the tyranny. The ſuſpicion was but too well founded. The philoſopher next day citing the two perſons before the council, they were condemned to death.

A very different character, however, is aſcribed to Empedocles by many other writers. He is ſaid to have conducted himſelf with the utmoſt pride and haughtineſs towards his fellow-citizens, and to have aſpired to divine honours; walking pompouſly about the country, and through the cities, habited like the gods, and ſeeking the plaudits of the people. He wore a golden crown on his head, with Delphic chaplets in his hands, and brazen ſandals on his feet, and was clothed in a robe of purple and gold, his hair being long and flowing.

The accounts of his death are not leſs various and contradictory. Some authors affirm, that thinking to paſs himſelf for a deity, and to perſuade the people that he had been taken directly up into heaven, he aſcended Ætna in the night, and threw himſelf head-long into the burning crater of the mountain, imagining that his death would remain for ever concealed from mortals; but that the treacherous mountain threw up one of his brazen ſandals, and thus expoſed the folly of the viſionary, who diſdained to be thought man.

> "—— Deus immortalis haberi
> Dum cupit Empedocles ardentem frigidus Ætnam
> Inſiliit." Hor. Ars Poet. v. 465.

Others, however, admitting that he periſhed in mount Ætna, aſſert that, impelled by his paſſion for the ſtudy of nature, he reſolved to examine the crater of that volcano, and that having ventured too far, he accidentally fell into the burning gulf. Some authors, again, have affirmed, that he broke his leg, by falling from a chariot, which brought on a diſeaſe that proved fatal. Others pretend that he terminated his own exiſtence, ſome ſay by throwing himſelf into the ſea, and ſome by ſtrangulation with a rope: while others maintain that he died a natural death, at the age of 77 years. But the moſt commonly received opinion, notwithſtanding theſe contradictions, is, that this philoſopher, being extremely advanced in years, accidentally fell into the ſea, and was drowned, about 440 years before Chriſt, or in the 84th Olympiad. Timæus relates, that, towards the cloſe of his life, Empedocles went into Greece, and never returned, and on this account, the exact time and manner of his death remain unknown. According to Ariſtotle, he died at the age of 60 years. Some writers make a diſtinction between Empedocles the philoſopher, and another who was a poet. Caſtellani, upon what authority we know not, ſtates that Empedocles, the philoſopher and poet, was the ſon of Meto, and grandſon of Empedocles, who was an excellent poet.

A ſtatue was erected to the memory of Empedocles at Agrigentum. See Caſtellani Vit. Medicor. Illuſt. Mangeti Bibliotheca Scriptor. Med. Haller. Bibl. Med. Pract. Dict. Hiſtorique. Brucker's Hiſt. Philoſ. by Enf. vol. i.

EMPERESS, Empress, *Imperatrix*, the feminine of emperor; the wife or widow of an emperor; or a princeſs who is the ſupreme ruler of an empire in her own right.

Emperess, is alſo uſed in the *Ancient French Poetry*, for a particular kind of rhime, thus denominated by way of excellence.

The "rhime emperiere" was a ſort of crowned rhime, wherein the ſyllable that made the rhime was immediately preceded by two other like ſyllables of the ſame termination, which made a kind of echo, called the *triple crown;* and which, to the ſhame of the nation, (as ſome of their late authors expreſs it,) their beſt ancient poets took for a wonderful beauty and excellence.

Fa. Mourgues, in his treatiſe on French poetry, gives us an inſtance very proper to raiſe contempt of the miſerable taſte of that age, which knew no way of expreſſing that the world is impure, and ſubject to change, ſo excellent, as by ſaying,

> "Qu'es tu qu'un imonde, monde, onde."

EMPEREUR, Constantine, L', in *Biography*, a learned divine, was a native of Holland, where he took the degree of doctor of theology, and became diſtinguiſhed in oriental literature and Jewiſh antiquities. He was profeſſor of theology and Hebrew at Harderwyck during eight years, and then was appointed profeſſor of Hebrew at Leyden in 1627. He died in 1648, a ſhort time after he had been appointed theological profeſſor at Leyden. He obtained the character of a zealous defender of the Chriſtian religion, againſt the objections of the Jews. He was the friend of the moſt learned men of his age, *viz.* of Heinſius, Buxtorf, &c. and offered to ſuperintend an impreſſion of their Talmudical dictionary in Holland. His works were chiefly theological, and highly eſteemed by his contemporaries. Moreri.

EMPERICHORESIS. See Circumincession.

EMPEROR, as far as this word denoted formerly the head of the German empire. See Germany.

Emperor, *Imperator*, among the *Ancient Romans*, ſignified a general of an army, who, for ſome extraordinary ſucceſs, had been complimented with this appellation. It was emphatically beſtowed by the ſoldiers, when, on the field of battle, they proclaimed their victorious leader worthy of that title. When the Roman emperors aſſumed it in that ſenſe, they placed it after their name, and marked how often they had taken it. Thus Auguſtus having obtained no leſs than twenty famous victories, was as often ſaluted with the title emperor; and Titus was denominated emperor by his army, after the reduction of Jeruſalem. See Augustus and Titus.

Afterwards it came to denominate an abſolute monarch, or a ſupreme commander of an empire; a Roman emperor, &c. In this ſenſe Julius Cæſar was called emperor, and the title deſcended with the dignity to Octavius Auguſtus, and the ſucceeding emperors.

In ſtrictneſs, the title emperor does not, and cannot add any thing to the rights of ſovereignty; its effect is only to give precedence and pre-eminence above other ſovereigns; and as ſuch, it raiſes thoſe inveſted with it to the ſummit of all human greatneſs.

The emperors, however, pretend, that the imperial dignity is more eminent than the regal; but the foundation of ſuch prerogative does not appear: it is certain, the greateſt, moſt ancient, and abſolute monarchs, as thoſe of Babylon, Perſia, Aſſyria, Egypt, Macedonia, &c. were called by the name of *kings*, in all languages, both ancient and modern. See King.

It is diſputed, whether or not emperors have the power of diſpoſing of the regal title. It is true, they have ſometimes taken upon them to erect kingdoms; and thus it is that Bohemia and Poland are ſaid to have been raiſed to the dignity; thus alſo, the emperor Charles the Bald, in the year 877, gave Provence to Boſon, putting the diadem on his head, and decreeing him to be called *king*, "Ut more priſcorum imperatorum regibus videretur dominari." Add, that the emperor Leopold erected the ducal Pruſſia into a kingdom, in favour of the elector of Brandenburg; and though ſeveral of the kings of Europe refuſed for ſome time to acknowledge him in that capacity, yet by the treaty of Utrecht, in 1712, they all concurred.

In the Eaſt, the title and quality of emperor are more frequent than they are among us; thus, the ſovereign princes of China, Japan, Mogul, Perſia, &c. are all emperors of China, Japan, &c.

In the year 1723, the czar of Muſcovy aſſumed the title of emperor of all Ruſſia, and procured himſelf to be recognized as ſuch by moſt of the princes and ſtates of Europe. See Russia.

In the Weſt, the title has been a long time reſtrained to the emperors of Germany. The firſt who bore it was Charlemagne, who had the title emperor conferred on him by pope Leo III. though he had all the power before. His empire, however, was of no long duration. When the German branch of his family became extinct, the Germans exerciſed the right inherent in a free people, and, in a general aſſembly of the nation, elected Conrad count of Franconia emperor. After him Henry of Saxony, and his deſcendants, the three Othos, were placed, in ſucceſſion, on the imperial throne, by the ſuffrages of their countrymen: the extenſive territories of the Saxon emperors, their eminent abilities, and enterpriſing genius, not only added new vigour to the imperial dignity, but raiſed it to higher honour and pre-eminence. (See Otho.) But while the emperors, by means of new titles and new dominions, gradually acquired additional authority and ſplendour, the nobility of Germany went on at the ſame time extending their privileges and juriſdiction. Upon the whole, the imperial prerogatives were formerly much more extenſive than they are at preſent. At the cloſe of the Saxon race, A.D. 1024, they exerciſed the right of conferring all the great eccleſiaſtical benefices in Germany; of receiving the revenues of them during a vacancy; of ſucceeding to the effects of inteſtate eccleſiaſtics; of confirming or annulling the elections of the popes; of aſſembling councils, and of appointing them to decide concerning the affairs of the church; of conferring the title of king on their vaſſals; of granting vacant fiefs; of receiving the revenue of the empire; of governing Italy as its proper ſovereigns; of erecting free cities, and eſtabliſhing fairs in them; of aſſembling the diets of the empire, and fixing the time of their duration; of coining money, and conferring the ſame privilege on the ſtates of the empire; and of adminiſtering both high and low juſtice within the territories of the different ſtates. But in the year 1437, at the period of the extinction of the emperors of the families of Luxemburgh and Bavaria, they were reduced to the right of conferring all dignities and titles, except the privilege of being a ſtate of the empire; of *preces-primariæ*, or of appointing once during their reign a dignitary in each chapter, or religious houſe; of granting diſpenſations with reſpect to the age of majority; of erecting cities, and conferring the privilege of coining money; of calling the meetings of the diet, and preſiding in them.

In the one period, the emperors appear as mighty ſovereigns, with extenſive prerogatives; in the other, as the heads of a confederacy, with very limited powers. The revenues of the emperors decreaſed ſtill more than their authority. The early emperors, particularly thoſe of the Saxon line, beſides their vaſt patrimonial or hereditary territories, poſſeſſed an extenſive domain both in Italy and Germany, which belonged to them as emperors. Italy belonged to the emperors as their proper kingdom; and the revenues which they drew from it were very conſiderable. But the firſt alienations of the imperial revenue were made in this country. The Italian cities, having acquired wealth, and aſpiring at independence, purchaſed their liberty from different emperors. Many diſtricts, poſſeſſed by the emperors, which were intermixed with the eſtates of the dukes and barons, were ſeized by the nobles, during the conteſts that took place between the emperors and the court of Rome. The emperors were alſo almoſt entirely robbed of their caſual revenues; the princes and barons appropriating to themſelves taxes and duties of every kind, which had been uſually paid to them. From the reign of Charles IV., whom Maximilian called the peſt of the empire, the emperors were reduced to the neceſſity of depending entirely on their hereditary dominions, as the only ſource of their power, and even of their ſubſiſtence. Pfeffel Abregé de l'Hiſt. d'Allem.

One principal cauſe of the degradation of the emperors was the aggrandizement of the clergy. The popes, before the firſt period above mentioned, A.D. 1024, had been dependent on the emperors, and indebted for their power as well as dignity to their beneficence and protection. But they afterwards began to claim a ſuperior juriſdiction; and in virtue of authority, which they pretended to derive from heaven, tried, condemned, excommunicated, and depoſed their former maſters. Pope Gregory VII. combined political diſcernment and ſagacity with his preſumption and violence; and commenced his rupture with Henry IV. upon a pretext that was popular and plauſible. He complained of the venality and corruption with which the emperor had granted the inveſtiture of benefices to eccleſiaſtics. All the cenſures of the church were denounced againſt Henry; and the moſt conſiderable of the German princes and eccleſiaſtics were excited to take arms againſt him. So ſucceſsful was the court of Rome in inflaming the ſuperſtitious zeal, and conducting the factious ſpirit of the Germans and Italians, that an emperor, diſtinguiſhed not only for many virtues, but poſſeſſed of conſiderable talents, was at length obliged to appear as a ſupplicant at the gates of the caſtle in which the pope reſided, and to ſtand there three days, bare-footed, in the depth of winter, imploring a pardon, which was at length obtained with difficulty. This act of humiliation degraded the imperial dignity. Nor was the depreſſion momentary. The conteſt between Gregory and Henry gave riſe to the two powerful factions of the Guelfs and Ghibellines; the former of which ſupporting the pretenſions of the popes, and the latter defending the rights of the emperor, kept Germany and Italy in perpetual agitation during three centuries. A regular ſyſtem for humbling the emperors, and circumſcribing their power, was formed and uniformly adhered to during that period. The decline of the imperial authority may partly be aſcribed to the change which took place with regard to the mode of their election. During a long period, all the members of the Germanic body aſſembled, and choſe the perſon whom they appointed to be their head; but amidſt the violence and anarchy which prevailed for ſeveral centuries in the empire, ſeven princes, who poſſeſſed the moſt extenſive territories, and who had obtained an hereditary title to the great offices of the ſtate, acquired the excluſive privilege of nominating the emperor. This right was confirmed to them by the golden bull; the mode of exerciſing it was aſcertained; and they were dignified with the appellation of *Electors*. Theſe electors, by their extenſive power, and the diſtinguiſhing privileges which they poſſeſſed, became formidable to the emperors, with whom they were placed almoſt on a level in ſeveral acts of juriſdiction. See Elector, and Diet.

To the privileges and powers formerly belonging to the emperors, and which have been above enumerated, ſome have added, 1. That all the princes and ſtates of Germany are obliged to do them homage, and ſwear fidelity to them. 2. That they, or their generals, have a right to command the forces of all the princes of the empire, when united together. 3. That they receive a kind of tribute from all the princes and ſtates of the empire, for carrying on a war which concerns the whole empire, which is called the *Roman month*. As to the preſent mutilated ſtate of the German empire, ſee Elector and Germany.

The kings of France were anciently alſo called emperors, at the time when they reigned with their ſons, whom they aſſociated to the crown: thus, Hugh Capet having aſſociated his ſon Robert, took the title of emperor, and Robert that of king; under which titles they are mentioned in the hiſtory of the council of Rheims, by Gerbert, &c. King Robert is alſo called emperor of the French, by Helgau of Fleury. Lewis le Gros, upon aſſociating his ſon, did the ſame. In the firſt regiſter of the King's Charters, fol. 166, are found letters of Louis le Gros, dated in 1116, in favour of Raymond, biſhop of Maguelonne, wherein he ſtyles himſelf "Ludovicus, Dei ordinante providentia, Francorum imperator Auguſtus." The kings of England had likewiſe anciently the title of emperors, as appears from a charter of king Edgar: "Ego Edgarus Anglorum baſileus, omniumque regum inſularum oceani quæ Britanniam circumjacent, &c. imperator & dominus."

We alſo ſay the king of England, "Omnem habet poteſtatem in regno ſuo quam imperator vindicat in imperio:" whence the crown of England has been long ago declared in parliament to be an imperial crown.

Emperor, among *Hebrew Grammarians*, is an appellation given to a ſpecies of accents ſerving to terminate a ſenſe completely, and anſwers to our point. See Accent.

Emperor *Elect*. See Elect.

EMPETRON, in *Botany*, a name by which ſome authors, as Dodonæus, &c. have called the kali or glaſs wort. Ger. Emac. Ind. 2. See Kali.

EMPETRUM, from εν, *in* or *upon*, and πετρος, *a rock*, or *ſtone*, expreſſing its ſtony barren places of growth. Linn. Gen. 515. Schreb. 676. Sm. Fl. Brit. 1072. Mart. Mill. Dict. v. 2. Juſſ. 162. Gærtn. t. 106. Claſs and order, *Dioecia Triandria*. Nat. Ord. *Ericis affine*, Juſſ.

Gen. Ch. Male. *Cal.* Perianth in three deep, ovate, permanent diviſions. *Cor.* Petals three, ſometimes more, ovate-oblong, contracted at their baſe, larger than the calyx, withering. *Stam.* Filaments three, ſometimes nine, capillary, very long, pendulous; anthers erect, ſhort, deeply cloven.—Female. *Cal.* and *Cor.* as in the male. *Piſt.* Germen ſuperior, depreſſed; ſtyle ſhort, ſimple; ſtigmas nine, ſpreading, a little reflexed. *Peric.* Berry orbicular, depreſſed, of one cell, larger than the calyx. *Seeds* three or nine, ranged circularly, gibbous at the outer edge, angular at the other. The flowers are commonly dioecious, but ſometimes the two ſexes are found on the ſame plant, and even both organs united in one flower.

Eſſ. Ch. Male, Calyx deeply three-cleft. Petals three. Stamens capillary, from three to nine. Female, Calyx deeply three-cleft. Petals three. Stigmas nine. Berry ſuperior, with three to nine ſeeds.

The ſpecies are two.

1. E. *album*. Linn. Sp. Pl. 1450. (Erica coris folio decima; Cluſ. Hiſt. v. 1. 45. E. baccifera tenuifolia; Ger. em. 1381.) "Stem erect." Obſerved by Cluſius on ſandy heaths near Liſbon, bearing fruit early in November. He compares the berries, which are white, acid, and tranſparent, to pearls of an inferior kind. He generally found but three ſeeds in each, which accords with Gærtner's account of this ſpecies. The *ſtems* are ſhrubby, a foot and half high, erect, branched in a determinate order. *Leaves* ternate, evergreen, linear, obtuſe, revolute, ſmooth above, reſembling thoſe of many heaths. *Flowers* not obſerved. *Berries* lateral, ſolitary, the ſize of a moderate pea, reſembling thoſe of Miſſeltoe.

2. E. *nigrum*. Linn. Sp. Pl. 1450. Sm. Fl. Brit. 1072. Engl. Bot. v. 8. t. 526. (E. montanum, fructu nigro; Raii Syn. 444. Erica baccifera procumbens; Ger. em. 1383.) "Stems procumbent." Black Crow-berry, or Crake-berry. Plentiful on mountainous heaths in the north of England, as well as in Sweden, Lapland, Denmark, &c. bloſſoming in May, and ripening fruit in Auguſt. It differs from the former in its more humble and procumbent growth, and in having black berries, with nine ſeeds. *Flowers* reddiſh, axillary, plentiful about the tops of the laſt-year's branches. The fruit has a mild flavour of elder-

berries, and "affords ſuſtenance to ptarmigans, grouſe, partridges, and even to the hardy highlander himſelf."

EMPHASIS, in *Elocution*, a term generally, but abſurdly, uſed by modern writers, excluſively in the *ſingular* number. "Emphaſis," ſays Mr. Sheridan (Lecture iv.), "diſcharges in ſentences the ſame kind of office that accent does in words. As accent is the link which ties ſyllables together, and forms them into words; ſo emphaſis unites words together, and forms them into ſentences, or members of ſentences. As accent dignifies the ſyllable on which it is laid, and makes it more diſtinguiſhed by the ear than the reſt; ſo emphaſis ennobles the word to which it belongs, and preſents it in a ſtronger light to the underſtanding. Accent is the mark which diſtinguiſhes words from each other, as ſimple types of our ideas, without reference to their agreement or diſagreement. "Emphaſis is the mark which points out their ſeveral degrees of relationſhip," and the rank which they hold in the mind. Accent addreſſes itſelf to the ear only; emphaſis, through the ear, to the underſtanding. Were there no accents, words would be reſolved into their original ſyllables: were there no emphaſis, ſentences would be reſolved into their original words. And in this caſe, the hearer muſt be at the pains himſelf, firſt, of making out the words, and afterwards their meaning: and as this could not be done, without ſuch length of pauſes at the end of ſentences, and their ſeveral members, as would allow him time to revolve in his memory the ſounds which have been uttered, it would make the action of liſtening to diſcourſe laborious and diſguſtingly tedious. Whereas, by the uſe of accent and emphaſis, words, and their meaning, being pointed out by certain marks, at the ſame time that they are uttered, the hearer has all trouble ſaved, but that of liſtening; and can accompany the ſpeaker at the ſame pace that he goes, with as clear a comprehenſion of the matter offered to his conſideration as the ſpeaker himſelf has if the ſpeaker delivers himſelf well."

It is not very eaſy to diſcover what Mr. S. means, (even with his interpretation of the word accent,) when he ſays, that "were there *no accent*, words would be reſolved into their *original ſyllables*;" ſince monoſyllables, though denied the property of what is here called accent, are nevertheleſs admitted by Mr. S. and the grammarians in general to be words; and ſince, as will be ſhewn hereafter, the ear alone (unaſſiſted by the memory of impreſſions received through the eye) has even yet (with all the aſſiſtance derived from that *poiſe* and that *percuſſion* of particular ſyllables, ſo abſurdly confounded in the popular abuſe of the term accent) no poſſible means of diſtinguiſhing polyſyllabic words from ſucceſſive monoſyllables, when properly pronounced. Certainly he is not at all more intelligible, when he adds, "were there *no emphaſis*, ſentences would be reſolved into their *original words*;" or again, when he informs us, that "by the uſe of accent and emphaſis, *words, and their meaning*, are pointed out by certain marks, *at the ſame time* that they are uttered." That ſhifting the percuſſion, or varying the poiſe of ſimilar aſſociations of ſyllables, will eſſentially change the meaning even of words in their ſeparate capacity, (as *díffer, defér; déſert, deſért; préſent, preſént; réfuſe, refúſe; óbject, objéct; íncenſe, incénſe*, &c. ſee B. Jonſon's Gram.) and ſtill more of ſuch aſſociated ſyllables as may occaſionally be brought together in the compoſition of ſentences, muſt be readily allowed; and that the ſenſe of *all ſentences* would be much obſcured by the omiſſion, and of *many* entirely inverted by a tranſpoſition of the emphaſes: but ſtill the words, as words, and their meanings as words, (though not their ſpecific relations to the other words of the ſentence,) would be recognized "*at the ſame time* they were uttered," whether they were accompanied with emphaſes or not: and as for what is here miſcalled the accent, the *poiſe* at leaſt muſt of phyſical neceſſity be ſomewhere placed; and *ſpeech* without it could not be conducted at all. But Mr. S. never ſeems to have dreamed of ſubmitting either the proceſs or the nomenclature of elocution to phyſiological or critical analyſis. He uſed the terms of his art as he found them in the works of the grammarians and rhetoricians of modern times; and as their phraſeology was all confuſion and contradiction, his elucidations were not likely to be very ſatisfactory. The Lecture on Emphaſis, however, is by far the moſt valuable portion of this work.

"The neceſſity of obſerving propriety of emphaſis," ſays he, "is ſo great, that the true meaning of words cannot be conveyed without it. For the ſame individual words, ranged in the ſame order, may have ſeveral different meanings, according to the placing of the emphaſis. Thus, to uſe a trite inſtance, the following ſentence may have as many different meanings as there are words in it, by varying the emphaſis: "Shall you ride to town to-morrow?" If the emphaſis is on ſhall, as, *Shall* you ride to town to-morrow? it implies, that the perſon ſpoken to had expreſſed before ſuch an intention, but that there is ſome doubt in the queſtioner whether he be determined on it or not; and the anſwer may be, Certainly, or, I am not ſure. If it be on you, as, Shall *you* ride to town to-morrow? the queſtion implies that ſome one is to go, and do you mean to go yourſelf, or ſend ſome one in your ſtead? and the anſwer may be, No, but my ſervant ſhall. If on ride, as, Shall you *ride*, &c.? the anſwer may be. No, I ſhall walk, or go in a coach. If on town, as, Shall you ride to *town* to-morrow? the anſwer may be, No, but I ſhall ride to the foreſt. If on to-morrow, as, Shall you ride to town *to-morrow?* the anſwer may be, No, not to-morrow, but the next day."

Theſe obſervations and illuſtrations may ſerve to ſhew the importance of emphaſes in general; but they do nothing towards illuſtrating the ſpecific characteriſtics of ſuch emphaſes. Indeed, in all that Mr. S. has ſaid upon this ſubject, it ſhould ſeem as if he had no clear conception of any other ſpecies of emphaſis, than the emphaſis of force; and it is evident, indeed, that the conceptions of the generality of readers and reciters, practically, go no farther. Mr. S. does indeed ſay, in another place, "that emphaſis is of two kinds," (ſurely, then it ſhould have been that emphaſes are of two kinds,) "ſimple or complex. Simple, when it ſerves only to point out the plain meaning of any propoſition; complex, when, beſides the meaning, it marks alſo ſome affection or emotion of the mind; or gives a meaning to words, which they would not have in their uſual acceptation, without ſuch emphaſis. In the former caſe, emphaſis is little more than a ſtronger accent, with but little change of tone; when it is complex, beſides force, there is always ſuperadded a manifeſt change of tone. Simple emphaſis belongs to the calm and compoſed underſtanding; complex, to the fancy and the paſſions." But the concluding remark ſufficiently evinces how little the nature of theſe varieties was underſtood by this author, and how imperfectly the terms of his art were defined in his own mind; for it will preſently be ſhewn, that even without any neceſſity of appeal to the fancy and the paſſions, a much more complex ſyſtem of emphaſes is neceſſary fully to elicit, and agreeably to illuſtrate, the ſenſe of many paſſages. Mr. Cockin, in his "Art of delivering written Language," animadverts upon the want of clearneſs in this diſtinction, and upon the apparent confuſion between the ſignificant power of emphaſis and the various "tones, ſimply conſidered, of all the emotions of the mind;" and ſeems to imagine he has remedied the confuſion by contradiſtinguiſhing emphaſes into "emphaſis of ſenſe, and emphaſis of force;" and Mr. Walker, (Elements of Elocution, p. 190.) conſiders this diſtinction as having "thrown great light upon this abſtruſe ſubject." But as the emphaſis of force is moſt aſſuredly as indiſpenſable to the full expreſſion of the ſenſe, as any of the other *ſeveral* ſpecies of emphaſes, it is very queſtionable whether this pretended diſtinction does any thing more than render confuſion worſe confounded. Mr. Cockin proceeds; "now from the above account of theſe two ſpecies of emphaſis it will appear, that in reading, as in ſpeaking, the firſt of them muſt be determined entirely by the ſenſe of the paſſage, and always made alike: but as to the other, taſte alone ſeems to have a right of fixing its ſituation and quantity." Farther, "ſince the more eſſential of theſe two energies is ſolely the work of nature, (as appears by its being conſtantly found in the common converſation of people of all kinds of capacities and degrees of knowledge,) and the moſt ignorant perſon never fails of uſing it rightly in the effuſions of his own heart, it happens very luckily, and ought always to be remembered, that provided we underſtand what we read, and give way to the dictates of our own feeling, the emphaſis of ſenſe can ſcarce ever avoid falling ſpontaneouſly upon its proper place." That mere taſte has any thing to do with fixing the *ſituation* of the emphaſis of force (whatever it may have to do with its *quantity* or *degree*) we utterly deny; or that, in juſt reading or recitation, it can be determined by any thing but the *ſenſe* alone. And as for what is ſaid of even the moſt ignorant perſon never failing, in common converſation and the effuſions of his own heart, in the right application of the *emphaſis of ſenſe*, it is true of all the kinds of emphaſes; for, in ſpontaneous ſpeaking, all emphaſes are emphaſes of ſenſe; and in all other kinds of ſpeaking (reading or reciting) whatever emphaſes are not ſo, muſt be emphaſes of nonſenſe. Mr. Walker, indeed, has himſelf ſuggeſted a much more rational ſpecies of diſtinction, and has made ſome conſiderable advances towards a juſt ſyſtem or theory upon this ſubject, by drawing a clear line of demarcation between what, perhaps, might very properly have been called the inherent or *grammatical powers* of particular claſſes of words, and the arbitrary or *ſignificant emphaſes* of ſpecific words in a ſentence. Perhaps had Mr. W. ſo denominated them, not only his diſtinctions, ſo far as they go, might have been rendered more obvious, but the denomination itſelf would have led him to diſcover that there are ſtill diſtinct ſpecies of actual emphaſes, properly ſo called, which have eſcaped his obſervation. He would not then, perhaps, have told us, that "emphaſis, in the moſt uſual ſenſe of the word, is that ſtreſs with which certain words are pronounced, ſo as to be diſtinguiſhed from the reſt of the ſentence." He would have perceived that ſuch a definition was much too vague to meet even the full ſignification of the term in popular uſage: for no one does in reality apply the term emphaſis to the mere grammatical or inherent force that diſtinguiſhes, in all diſtinct and intelligible ſpontaneous ſpeech, the nouns and verbs above the articles, conjunctions, and prepoſitions. The term, on the contrary, always ſuppoſes ſome ſuperadded diſtinction given to a word or words of what deſcription ſoever, and conferring upon ſuch words a degree of importance in the ſentence, beyond what is inherent in their mere grammatical quality. Mr. W. proceeds, "among the number of words we make uſe of in diſcourſe, there will always be ſome which are more neceſſary to be underſtood than others: thoſe things with which we ſuppoſe our hearers to be pre-acquainted (he might have added, 'or which are neceſſary only for the mere grammatical connection of the more important words,') we expreſs by ſuch a ſubordination of ſtreſs as is ſuitable to the ſmall importance of things already underſtood; while thoſe of which our hearers are either not fully informed, or which they might poſſibly miſconceive, are enforced with ſuch an increaſe of ſtreſs, as makes it impoſſible for the hearer to overlook or miſtake them. Thus, as in a picture, the more eſſential parts of a ſentence are raiſed, as it were, from the level of ſpeaking; and the leſs neceſſary are, by this means, ſunk into a comparative obſcurity." This is both juſt and pertinent, and the ſimile at the concluſion is even more appoſite, than Mr. Walker ſeems himſelf to have been aware; for, to purſue the metaphor in elocution as in picture, it is not merely by the force of a line or the depth of a ſhadow, that all the varieties of emphatic effect are to be expected to be produced. "From this general idea of emphaſis," continues Mr. W., "it will readily appear of how much conſequence it is to readers and ſpeakers not to be miſtaken in it; the neceſſity of diſtinguiſhing the emphatical words from the reſt, has made writers on this ſubject extremely ſolicitous to give ſuch rules for placing the emphaſis as may, in ſome meaſure, facilitate this difficult part of elocution; but few have gone farther than to tell us that we muſt place the emphaſis on that word in reading which we ſhould make emphatical in ſpeaking; and though the importance of emphaſis is inſiſted on with the utmoſt force and elegance of language, no aſſiſtance is given us to determine which is the emphatic word, where ſeveral appear equally emphatical, nor have we any rule to diſtinguiſh between thoſe words which have greater, and thoſe which have a leſſer degree of ſtreſs; the ſenſe of the author is the ſole direction we are referred to, and all is left to the taſte and underſtanding of the reader."

He then proceeds to ſtate with high commendation the above-mentioned diſtinction of Mr. Cockin, whoſe definition he quotes as follows: "Emphaſis of force," he tells us, "is that ſtreſs we lay on almoſt every ſignificant word: emphaſis of ſenſe is that ſtreſs we lay on one or two particular words, which diſtinguiſhes them from all the reſt of the ſentence. The former ſtreſs," he obſerves, "is variable, according to the conception and taſte of the reader, and cannot be reduced to any certain rule: the latter," he ſays, "is determined by the ſenſe of the author, and is always fixed and invariable. This diſtinction, it muſt be owned," continues Mr. Walker, "is, in general, a very juſt one, and a want of attending to it has occaſioned great confuſion in this ſubject, even in our beſt writers. Thus, when the emphatical words were to be marked, by being printed in a different character, we find in ſeveral of the modern productions on the art of reading, that ſometimes more than half of the words are printed in italics, and conſidered as equally emphatical. The wrong tendency of ſuch a practice," continues Mr. W., "was never pointed out till the publication of the eſſay above-mentioned;" by the aſſiſtance of which Mr. W. profeſſes to endeavour to puſh his inquiries ſtill farther; "not only to eſtabliſh the diſtinction he has laid down, but to draw the line between thoſe two kinds of emphaſis, ſo as to mark more preciſely the boundaries of each. To this diſtinction of emphaſis he accordingly adds another, making a diſtinction of each into two kinds, according to the inflexion of voice they adopt; which, though of the utmoſt importance in conveying a juſt idea of emphaſis, had never been noticed by any of our writers on the ſubject." The diſtinction thus added is that which relates to the application of the riſing and falling inflexion, and which, though in reality ſuch inflexions apply not only to emphatic words, but in a ſmaller or greater degree to all the words and ſyllables of which language, properly delivered, is compoſed, (every ſyllable not delivered in a *monotone*, *i.e.* not ſung, having of neceſſity either an acute, a grave, or a circumflex accent,) is aſſuredly a diſtinction of much importance, in what relates to the practical adjuſtment of the emphaſis, and for the comprehenſion of Mr. Walker's theory, relative to which (imperfect as that theory, perhaps, may be) the ſtudent will do well to refer both to the "Elements" and to the "Rhetorical Grammar" of that elaborate profeſſor. "This," ſays Mr. W., "brings us to a threefold diſtinction of words, with regard to the force with which they are pronounced; namely, the conjunctions, particles, and words underſtood, which are obſcurely and feebly pronounced; the ſubſtantives, verbs, and more ſignificant words, which are firmly and diſtinctly pronounced; and the emphatical word, which is forcibly pronounced: it is the laſt of theſe only which can be properly ſtyled emphaſis; and it is to a diſcovery of the nature and cauſe of this emphaſis that all our attention ought to be directed. And firſt, we may obſerve, that if theſe diſtinctions are juſt, the common definition of emphaſis is very faulty. Emphaſis is ſaid to be a ſtreſs laid on one or more words to diſtinguiſh them from others: but this definition, as we have juſt ſeen, makes almoſt every word in a ſentence emphatical."

Mr. W. then adds, "the principal circumſtance that diſtinguiſhes emphatical words from others, ſeems to be a meaning which points out, or diſtinguiſhes, ſomething as diſtinct or oppoſite to ſome other thing. When this oppoſition is expreſſed in words it forms an antitheſis, the oppoſite parts of which are always emphatical. Thus, in the following couplet from Pope:

> 'Tis hard to ſay, if greater want of ſkill
> Appear in writing or in judging ill.

The words *writing* and *judging* are oppoſed to each other, and are therefore the emphatical words.

But this deſcribes only the emphaſis of antitheſis, which is certainly not the only ſpecies of emphaſis, properly ſo called, that is requiſite to well delivered ſpeech; for words are rendered important by appoſition, as well as by oppoſition; by their relative, and their abſolute conſideration in the ſentence, and by their reflective, as well as their antagoniſt meaning, and to aſcertain and exemplify all the varieties and circumſtances of emphaſes, were almoſt to illuſtrate the whole theory of the actual and practicable melody of ſpeech. The threefold diſtinction above quoted does, however, furniſh a clue to a part of this mazy labyrinth; and Mr. W.'s concluding definition, though imperfect, as excluding ſome eſſential claſſes of emphaſes, is ſtrictly applicable to the full extent of his view, which was certainly the moſt comprehenſive that had then been taken of the ſubject. "Emphaſis," ſays he, "when applied to particular words, is that ſtreſs we lay on words, which are, in contradiſtinction to other words, either expreſſed or underſtood. And hence will follow this general rule; wherever there is contradiſtinction in the ſenſe of the words, there ought to be emphaſis in the pronunciation of them; the converſe of this being equally true, wherever we place emphaſis we ſuggeſt the idea of contradiſtinction." Now though it is not true, that all emphaſis has an antitheſis, either expreſſed or underſtood, yet as the emphaſes of antitheſis conſtitute a very large and material claſs of theſe rhetorical diſtinctions, the following rules may be regarded as highly important. "If the emphaſis excludes the antitheſis, the emphatic word has the falling inflexion; if the emphaſis does not exclude the antitheſis, the emphatic word has the riſing inflexion. The grand diſtinction, therefore, between the two emphatic inflexions is this; the falling inflexion affirms ſomething in the emphaſis, and denies what is oppoſed to it in the antitheſis; while the emphaſis with the riſing inflexion, affirms ſomething in the emphaſis without denying what is oppoſed to it in the antitheſis; the former, therefore, from its affirming and denying abſolutely, may be called the ſtrong emphaſis; and the latter from its affirming only, and not denying, may be called the weak emphaſis."

They who purſue Mr. W. through all his diſtinctions of ſimple, double, and triple emphaſis, will undoubtedly, upon the whole, be much edified, though even with reſpect to the application of the inflexions they may not agree with him in every inſtance. But if Sheridan attempted nothing more than a practical elucidation of the application and miſapplication of emphaſis, without laying down any general principles, or rules of extenſive and perſpicuous application, or diſcriminations of the characteriſtic varieties of emphaſes; and if Cockin only ſuggeſted without properly defining the differences between the grammatical import, and the emphatic diſtinction of words; Mr. W. while he has in ſome inſtances well defined the principle of the application of the riſing, and the falling inflexions to emphatic words, has left it to more recent diſcovery to define, and to claſſify the ſeveral ſpecies of emphaſes, (properly ſo called,) and to point out the diſtinct properties, or actions both of the voice and the enunciation by which thoſe ſpecies are to be contradiſtinguiſhed. "All emphaſes," it is maintained by the lecturer on the ſcience and practice of elocution, "affect the words upon which they fall in the three predicaments, of time, of tune, and of force, but as ſome ſpecies of emphaſes require a preponderancy of one, and other ſpecies of another of theſe properties, emphaſes may properly be contradiſtinguiſhed into three kinds; emphaſis of time, or the condition of words rendered emphatical, by the encreaſed quantity aſſigned to the reſpective ſyllables; emphaſis of tune, or the condition of words rendered emphatical, by the diſtinction of a ſuperior degree of inflexion, or by a higher or lower pitch in the muſical ſcale; and emphaſis of force, or the condition of words rendered emphatical by the ſuperior energy with which they are uttered. And the adjuſtment of theſe reſpective varieties of emphaſes, to their reſpective occaſions, it is contended, is of equal importance with the ſelection of the proper ſituations for placing an emphaſis at all; ſince the ſenſe may be as completely perverted, or at leaſt the ear may be as much ſhocked by inſerting the emphaſis of force (a very common error in theatrical recitation,) where that of tune, or of quantity was required, as by placing it altogether on a wrong word. To elucidate this ſyſtem ſatisfactorily, would require more ſpace than can conveniently be ſpared, in a general dictionary of the circle of ſciences; but as there at preſent exiſts no printed copy of the lectures in queſtion, nor any book upon the ſubject to which the ſtudent can be referred, part of a column will not perhaps be miſapplied, by being dévoted to the ſubject. The kinds of emphaſes enumerated are principally as follows. 1. The objective emphaſis, or emphaſis of import, *i. e.* the ſtreſs of voice by which proportionate importance is given to the word or words, conveying the ſubſtantive matter, or leading object of the ſentence, as "I am deſirous of being acquainted with *the nature of Man.*" That is to ſay, "the nature of man is a ſubject to which I am deſirous of directing ſome enquiry;" an idea which may be expreſſed either with or without any reference to any other ſubject, either as aſſociated or rejected. In which latter caſe, no antitheſis is either expreſſed or implied, and the ſimple emphaſis of import is expreſſed, by an increaſed ſtreſs of the voice, thrown upon the whole of the ſyllables, compoſing the amalgamated ſubſtantive, or compound name of that object, to wit, "the nature of man." 2. Emphaſis of antitheſis, or that characteriſtic ſtreſs and inflexion of the voice by which the oppoſition between two ideas, or parts of a compound idea, is pointed out, and emphatically impreſſed upon the mind. The antitheſis may be either expreſſed or underſtood. Thus, if the preceding paſſage be requoted with an emphaſis upon the word nature only, and that emphaſis be principally ſpecified by a ſtrong circumflective accent (that is to ſay, by a partial increaſe of quantity and a ſpecific peculiarity of time) I am deſirous of becoming acquainted with the *nature* of Man;—the words have changed to a certain degree their ſignification; an antitheſis is underſtood; and the interpretation becomes "It is not the *hiſtory*—it is not the outward *form* and *complexion*, or any other particular incident relative to man, but his general nature, his phyſical and moral attributes that I am deſirous of knowing." Again, if the ſingle word Man be rendered emphatic by ſuperadding to the cuſtomary energy of the cloſing poiſe or final heavy ſyllable a certain portion of the ſame ſpecies of time, "I am deſirous of becoming acquainted with the nature of *man*," will then by another implied antitheſis come to ſignify, "It is not with the nature of ſtones, and earths, and ſhrubs, and herbs, and brute animals, that I am deſirous of becoming acquainted, but with that of man." Of the direct or expreſſed antitheſis we have an illuſtration in the following ſentence. "It is not with the nature of *Màn*, but with the nature of *Gód*, that I am deſirous of being acquainted." Upon this ſpecies of emphaſis little need be added to what has already been ſaid by Mr. Walker. 3. The emphaſis of coincidence, or the level and equal ſtreſs of the voice upon two or more words either in the ſame or different members of a ſentence; by which the relationſhip, agreement, and equal importance of the annexed ideas are indicated: as—"The *ſtature*, the *form*, and the *complexion* of man, as well as his *moral* and *phyſical attributes* are parts of his nature; and his *hiſtory* muſt be ſtudied that his nature may be underſtood." In this inſtance all the words diſtinguiſhed by italics demand the emphaſis of coincidence: a ſpecies of emphaſis which is expreſſed more by its time, or quantity, than either by its inflexion or its force. As this is the ſpecies of emphaſis that is leaſt obtruſive, it is that which may be uſed with the greateſt frequency and freedom. 4. Complicated emphaſes. Sometimes all the different kinds of emphaſes are mingled in one ſentence; ſo that ſeveral different words, or pairs of words, require to be diſcriminated in all the varieties and degrees of time, tune, and force. "It is not the NATURE of **Man** that I am *deſirous* of *STUDYING;* but the LAWS of **God** that I am *anxious* to *COMPREHEND*." Here NATURE, LAWS; **Man**, **God**; *deſirous*, *anxious; STUDYING*, *COMPREHEND*, require to be reſpectively balanced and coupled in the mind by appropriate reſponſes of quantity, tune, and force; which if the ſentence flowed ſpontaneouſly would as ſpontaneouſly be adjuſted in all propriety, but the due application and apportioning of which to written language conſtitutes one of the moſt difficult parts of the art of reading.

There is one thing more which it is neceſſary to obſerve on the ſubject of emphaſis, and then we have done with this long article. It has been miſtakenly ſuppoſed, that the diſtinction of emphaſis neceſſarily belongs to ſingle words; nay ſome there are, who, confounding emphaſis with mere percuſſion, would confine it to ſingle ſyllables; but the fact is, that emphaſis (properly ſo called) belongs not either to the ſyllabic ſeparation, or grammatical ſtructure of words, but to the idea; and whether the ſubſtantive idea be expreſſed by a ſimple or by a compound name, the *whole* name of that idea, not a part only of that name, muſt bear the equal impreſs of that emphaſis:—thus, for example, in the famous reply of the firſt William Pitt to Mr. Walpole,—"But youth it ſeems is not my only crime; I have been accuſed of acting a theatrical part." Here neither the word *acting*, nor the word *theatrical*, nor the word *part*, taken ſeparately, deſignates the jut of the accuſation, or conſtitutes the name of the idea included in the accuſation: for if we read, "I have been accuſed of *acting* a theatrical part," placing the emphaſis only on the word acting; may it not properly be aſked—Why, what would you do with a theatrical part but *act it?* If the emphaſis be placed on theatrical, "I have been accuſed of acting *a theatrical* part:"—what part ſhould be *acted*, but one that is theatrical?—if upon the word part alone—I have been accuſed of acting a theatrical *part?*—what that is theatrical can be acted but a *part?* The whole latter member of the ſentence conſtitutes therefore the jut or object of the accuſation.—"I have been accuſed"—(of what?)—*of acting a theatrical part!*" Theſe words therefore conſtitute, accordingly, the amalgamated ſubſtantive, or compound name of the indiviſible, accuſatory idea, and muſt receive throughout an equal portion of *objective emphaſis*. Not that the ſyllables are thereby to be rendered equally forcible, or to be otherwiſe reduced to one monotonous level. They are only to receive one common ſuperaddition of emphatic force; and as independently of ſuch ſuperaddition, they would have differed among themſelves in pauſe, quantity, accent, and grammatical, or inherent force; in all thoſe particulars they will ſtill continue to differ.

Such is the preſent ſtate of diſcovery and aſcertainment to which enquiries had been conducted upon the ſubject of emphaſis: by which it ſhould ſeem, that it conſtitutes an eſſential part of the theory and practice of the melody of ſpeech; to which we refer the reader; concluding the preſent article with the following definition. "Emphaſes conſiſt in the ſuperadditional importance given to particular words or parts of a ſentence, by an increaſed ſtreſs, tune, quantity, or force in the pronunciation of ſuch words or parts of a ſentence; and by which their relative importance is pointed out, and the contraſts and aſſimilations of different members of a deſcription, argument, or poſition, are diſcriminated to oral perception." Whether it be poſſible, or even deſirable that a ſyſtem of notation (the want of which is lamented by Sheridan and others) ſhould be invented and applied to the indication of theſe varieties, is a queſtion that may belong to the article NOTATION; but which ſhall not be here diſcuſſed.

EMPHATICAL, is uſed by the *Ancient Philoſophers*, to expreſs thoſe apparent colours which are often ſeen in clouds before the riſing or after the ſetting of the ſun; or thoſe in the rainbow, &c.

Theſe, becauſe they are not permanent and laſting, they will not allow to be true colours; but, ſince theſe emphatical colours are light modified chiefly by refractions and with a concurrence of reflections, and ſome other accidental variations; and ſince they are the proper objects of ſight, and capable as truly to affect it as other permanent colours are, there is no reaſon for excluding them from the number of true and genuine colours, ſince all other colours are only modifications of light, as theſe are.

EMPHEREPYRA, in *Natural Hiſtory*, a genus of ſiderochita, compoſed of various cruſts or coats, ſurrounding a nucleus of the ſame matter and ſtructure with themſelves. See Siderochita.

Of this genus we have five ſpecies. Hill's Hiſt. Foſſils, p. 532.

EMPHRACTIC, in *Pharmacy*, the ſame with *emplaſtic*. The word is formed from the Greek εμφρακτω, *I ſtop*.

EMPHRAXIS, in *Medicine*, an obſtruction in any part.

EMPHRUE, in *Botany*, the name given by the people of Guinea to a ſpecies of tree, the leaves of which they boil in wine, and give as a great reſtorative in caſes of weakneſs and decay. Its leaves are exactly of the ſhape of thoſe of the common mulberry. but they are not indented at the edge. Petiver has thence called it "arbor Guineenſis mori folio non crenato." Phil. Tranſ. N° 232.

EMPHYSEMA. The common meaning of this word, in *Surgery*, is an inflation of the texture parts, in conſequence of air getting out of a breach in the lungs, and paſſing into the communicating cavities of the cellular ſubſtance on the outſide of the cheſt, through another breach exiſting at the ſame time in the pleura coſtalis, or membrane lining the thorax. However, there are ſome leſs frequent caſes of emphyſema, which are not comprehended in the preceding definition, as will be explained in the courſe of the preſent article. The term is derived from the Greek εμφυσαω, *to inflate*. Dr. Halliday, in a late ingenious eſſay on the ſubject under conſideration, deſcribes the following as the ſymptoms of an emphyſema, when the affection proceeds from an injury of the thorax. A conſtant pain takes place in the ſide, that has been hurt. At firſt, the ſuffering is not increaſed even by a very full inſpiration; but, no great length of time elapſes, before a very conſiderable difficulty of breathing occurs, and the patient complains of a ſenſation, as if cords were drawn acroſs the cheſt, and of a peculiar tightneſs at the ſcrobiculus cordis. If the part, where the pain and uneaſineſs were firſt felt, is now examined, a ſoft puffy tumour may be noticed, which is ſo very prominent as to prevent the ribs immediately under it from being felt. This tumour increaſes very rapidly, and is ſoon diffuſed over all the cheſt; but is particularly conſpicuous on the neck, breaſt, and face. The rapidity, with which it now ſpreads over the whole ſurface of the body, is amazing, and, in many places, the ſkin is elevated ſeveral inches from the ſubjacent bones and muſcles. When the ſwelling has become general, the patient finds it extremely difficult both to expire and inſpire; the motion of the extremities is very much impeded, and, indeed, when the ſkin is conſiderably elevated, ſuch motion is almoſt entirely prevented. The integuments crackle under the hand; the ſkin is much paler than natural, feels cold, and when ſtruck, ſounds like a wet drum. The air may, in general, be eaſily preſſed from any part; but it returns to the ſame place again as ſoon as the preſſure is removed. The reſpiration is exceedingly laborious, and quick. The patient inſpires with a ſudden effort, and the air, in paſſing the epiglottis, makes a peculiar noiſe. Expiration follows inſpiration almoſt inſtantaneouſly, and is performed with a deep ſigh, or rather groan. The patient is incapable of lying with comfort on either ſide of his body, and feels moſt eaſe, and breathes beſt, when ſitting half erect in bed. The ſkin and extremities feel very cold. The pulſe is ſometimes quick and hard; at other times, it is hard and full; but it can only be felt with ſome difficulty. The eye-lids are frequently ſo puffed up that the patient cannot ſee; the features are very much deformed; and the lips aſſume a purple, or rather a livid hue. At the beginning of the caſe there is generally a ſhort tickling cough, which increaſes with the other ſymptoms, ſo as to become almoſt inceſſant. What the patient ſpits up is generally very frothy and mixed with blood. The tongue is dry, and the patient complains of a conſtant thirſt. The voice becomes very weak, and unleſs the effuſed air is ſpeedily let out, ſo as to reduce the ſwelling and preſſure, the patient dies ſuffocated. (See obſervations on Emphyſema, 1807.) It is utterly impoſſible for any one to underſtand the ſubject of emphyſema, without previouſly having ſome idea of the manner in which the function of reſpiration is naturally carried on. He muſt at leaſt know, that, in the perfect ſtate, the ſurface of the lungs always lies in cloſe contact with the membrane lining the ribs, both in inſpiration and expiration. The lungs themſelves are only paſſive organs, and are quite incapable, by any action of their own, of expanding and contracting, ſo as to maintain their external ſurface conſtantly in contact with the inſide of the thorax, which is continually undergoing an alternate change of dimenſions. Every muſcle that has any concern in producing an enlargement, or diminution, of the cheſt, muſt contribute to the effect of adapting the volume of the lungs to the ſize of the cavity in which thoſe organs are contained. This muſt happen while there is no communication between the cavity of the pleura and the external air, and while there is no breach of continuity in the ſurface of the lungs themſelves. In the act of inſpiration, the thorax becomes enlarged in every direction, the lungs are proportionally expanded, and the air entering through the windpipe, into the air-cells of theſe organs, prevents the occurrence of a vacuum. On the other hand, in the act of expiration, certain muſcles diminiſh the capacity of the thorax, and the lungs being of courſe compreſſed, a large portion of the air, which had juſt before been inhaled in the preceding inſpiration, is again expelled from the trachea.

The few obſervations, already made, muſt render it obvious to every reader, that by the conſtant continuance of the ſurface of the lungs in cloſe contact with the inſide of the cheſt, both in its enlarged and diminiſhed ſtate, the air is regularly drawn into, and expelled out of the air-cells of thoſe important viſcera. It muſt alſo be manifeſt, that immediately a free and direct opening is made through the ſkin and muſcles into the cavity of the cheſt, ſome air muſt enter through the wound, and inſinuate itſelf into this laſt ſituation, on the dimenſions of the thorax being enlarged by the action of the muſcles of inſpiration. The lungs on the wounded ſide, of courſe, remain collapſed, and leſs air is drawn into the trachea, in proportion as a larger quantity accumulates between the inſide of the cheſt and the outſide of the lungs. In this manner, the expanſion of theſe latter organs on one ſide becomes gradually more and more obſtructed. A certain part of the accumulated air, it is true, is forced out of the wound again in each expiration; but a larger quantity enters at every inſpiration, and the lungs on the injured ſide become at laſt quite collapſed.

Caſes of this kind, by which we imply wounds, attended with a free and direct opening into the cavity of the cheſt, can never be attended with any ſerious degree of emphyſema. If the wound be not quite ample and ſtraight, a certain quantity of air, expelled at each expiration, inſtead of getting out of the external orifice, may undoubtedly inſinuate itſelf into the adjoining cellular ſubſtance, and occaſion ſome emphyſematous ſwelling. However, this never ſpreads, under ſuch circumſtances, to any conſiderable extent.

The emphyſema alſo, abſtractedly conſidered, is never productive of much danger, when there is a free and direct opening into the cheſt; for it will be preſently underſtood that the danger, in emphyſematous caſes, depends on the manner in which the air is confined in the cavity of the cheſt, ſo as to produce ſuch a degree of preſſure on the mediaſtinum and diaphragm, as obſtructs the function of the oppoſite lung, and occaſions a fatal ſuffocation. Now the very exiſtence of a free opening removes the poſſibility of the air accumulating in ſuch a manner in the cheſt, as to cauſe any dangerous degree of preſſure on the diaphragm and other lung. This latter ſupports life, while the lung on the wounded ſide lies quietly collapſed, till the wound in the parietes of the cheſt has healed, and the air has been abſorbed.

The foregoing remarks muſt make us percieve what wiſdom there is in the arrangement, of having the cheſt divided into two cavities, which have no communication with each other. If things were not ſo ordained, ſuffocation would be a common conſequence of every large wound, that extended into the cheſt. Bertrandi informs us, that whenever a free opening is made into each ſide of an animal's thorax, the lungs collapſe, and ſuffocation is always the conſequence.

However, wounds which merely penetrate the cheſt, without wounding the lungs, are never attended with any conſiderable degree of emphyſema. Whatever emphyſematous ſwelling does ariſe is alſo produced by the external air, which paſſes into the thorax through the wound, in the act of inſpiration, and out of the orifice of the injury again, when the patient diminiſhes the capacity of the cheſt in expiration.

The caſes of emphyſema, moſt apt to be attended with alarming ſymptoms, interrupted reſpiration, and an extenſive diffuſion of air in the cellular ſubſtance of the body, are commonly produced by narrow oblique ſtabs, which penetrate the parietes of the cheſt, the pleura coſtalis, and pleura pulmonalis, ſo as to make an opening into the air-cells of the lungs. Emphyſema alſo frequently aſſumes the ſame urgent and dangerous form, in caſes of fractured ribs, the ſharp ſpiculæ of which, being driven inward, tear the pleura coſtalis, pleura pulmonalis, and ſurface of the lungs themſelves. The latter inſtances differ from wounds in the circumſtance of there being no breach of continuity in the integuments. We have already explained, that whatever air inſinuates itſelf into the cellular ſubſtance, in wounds, which ſimply enter the cheſt without injuring the lungs, muſt be derived from without; that is, it firſt paſſes into the thorax through the wound. But when emphyſema ariſes from narrow oblique ſtabs, which enter the cheſt and injure the lungs; or when the affection originates from the pleura coſtalis, pleura pulmonalis, and part of the ſubſtance of the lungs being torn by the ſharp points of a broken rib; whatever air becomes diffuſed in the cellular ſubſtance, firſt eſcapes from the breach in the air-cells of the lungs into the cavity of the thorax, and thence is expelled through the wound, or laceration in the pleura coſtalis, into the common cellular ſubſtance, ſituated on the outſide of this latter membrane. In wounds, which ſimply enter the thorax, without injuring the lungs, the air paſſes through the opening, into the cavity of the pleura in inſpiration, at the ſame time, and from the ſame cauſes, that the air alſo enters the lungs through the trachea. Circumſtances, however, are exceedingly different, when emphyſema ariſes from narrow oblique ſtabs, or fractures of the ribs, attended with an injury of the lungs. In the firſt of theſe caſes the air cannot enter the cavity of the cheſt in the ſame manner as it does when there is a free and direct opening made in the parietes of the thorax. In the ſecond inſtance, (namely, fractured ribs,) there is no external orifice at all. Both theſe latter kinds of caſes, being alſo accompanied by a wound of the lungs, are eſſentially different, in many reſpects, from ſuch examples of emphyſema as proceed from a wound, which only enters the cheſt without doing any miſchief to the lungs. When the ſurface of theſe organs is wounded, no ſooner does the cheſt become expanded in the act of inſpiration, than ſome of the air eſcapes from the breach in the ſubſtance of the lungs, gets into the cavity of the pleura, and afterwards inſinuates itſelf, through the opening in the pleura coſtalis, into the common cellular ſubſtance.

We ſhall next endeavour to make the reader underſtand more clearly the cauſe of the air collecting in the cheſt, and becoming effuſed in ſuch caſes of emphyſema as proceed from wounds, or injuries, which cauſe a breach either in the pleura pulmonalis alone, the pleura pulmonalis and pleura coſtalis together, or in the integuments, muſcles, and pleura coſtalis, without the pleura pulmonalis being at all concerned. We ſhall enter into this part of the ſubject rather fully, becauſe it is by no means well underſtood by the generality of ſurgeons, and, without a clear comprehenſion of it, the practitioner muſt feel completely in the dark, in regard to the right mode of treating the affection.

Dr. Halliday notices, that the lungs in the thorax have often, and not unaptly, been compared to a bladder in a cloſe pair of bellows; but, if we ſuppoſe the bellows to be divided into two compartments, and each of theſe to contain a bladder, which mutually communicate with each other, and with the external air by means of a tube, which is exactly adapted to the nozzle of the bellows, and which admits the air only into the cavity of the bladders, and not into the ſpace betwixt the bladders and bellows, we ſhall then have a perfect repreſentation of the mechanical ſtructure of the thorax. The bellows will repreſent the thorax divided in the middle by the mediaſtinum; the bladders will repreſent the lungs of the right and left ſides; and the tube, which communicates with the bladders and the external air, will repreſent the trachea. The only thing which is wanting to render this mechanical repreſentation perfect is, that the bladders ſhould exactly fill the bellows, ſo as to leave no air betwixt them and the bellows.

It is evident, ſays Dr. Halliday, that when we lift up the handle of the bellows, the bladders will be filled by the external air ruſhing in through the tube, which communicates with both, and that, when we depreſs the handle, the air will be again expelled. Dr. Halliday conceives that this is exactly the way in which the lungs are filled and emptied in reſpiration. The cavity of the thorax being enlarged, by the contraction of the diaphragm and intercoſtal muſcles, &c. a vacuum is formed, into which the air ruſhes through the trachea, and we perform what is called *inſpiration;* whereas, by the contraction of the abdominal muſcles, and relaxation of others, the cavity of the thorax is diminiſhed, and the air is expelled, or we *expire.*

The bellows and bladders, continues Dr. Halliday, will alſo ſerve to illuſtrate the caſes of injury mentioned as giving riſe to emphyſema, and firſt as occaſioned by the pleura pulmonalis of one ſide being wounded, or ulcerated. This caſe is, in many reſpects, the ſame as if an opening were made in one of the bladders, and which opening would form a communication with the ſpace betwixt the bellows and bladder on one ſide. Now, ſuppoſe that this takes place while the handle of the bellows is depreſſed, as ſoon as the handle is raiſed, air will ruſh into the ſpace betwixt the bladder and bellows, and, if you keep the handle up for a little time, the bladder will collapſe altogether, and the place which it naturally occupied, when diſtended, will now be occupied by the air. If we attempt to force out the air by depreſſing the handle of the bellows, we ſhall find that this cannot be done; for there is no direct communication betwixt the bellows and external air; and, as the effuſed air preſſes equally on all parts of the collapſed bladder, it cannot eſcape through it. Dr. Halliday next explains, that by the action of the muſcles of inſpiration, the preſſure is removed from the ſurface of the wounded lung, and the air, which ſhould have ruſhed in and diſtended the lung, now paſſes through the wound, into the ſpace betwixt the pleura pulmonalis and pleura coſtalis. In the living body the whole of the air inſpired will not be thus effuſed; but, as it muſt paſs through the lung, it will alſo at firſt diſtend it, more or leſs, according to the ſize of the opening in the pleura pulmonalis, and this partial dilatation of the wounded lung will always happen while air continues to be inſpired on that ſide. As ſoon as expiration begins, the general cavity of the thorax being thereby diminiſhed, the effuſed air will be compreſſed againſt the wounded lung; but none of the air which has eſcaped can re-enter the lung again, becauſe the whole of the air contained in the lung muſt be forced out, and the preſſure againſt every part of the collapſed lung being equal, will prevent the effuſed air from ſeparating any part, ſo as to make a paſſage for itſelf into the trachea. In this manner freſh air is accumulated in the ſpace betwixt the pleura at every inſpiration, while none is allowed to eſcape during expiration, and the quantity accumulated at laſt will be equal to that which was received into the other lung, during the moſt powerful inſpiration after the accident. Dr. Halliday next notices, that this kind of accumulation of air in the cheſt has been denominated *thoracic emphyſema*, and has been ſuppoſed to have ſometimes proved fatal, without any more extenſive diffuſion of the air.

Dr. Halliday afterwards informs us, that when an opening exiſts both in the pleura pulmonalis and pleura coſtalis, the ſame circumſtances happen as in the foregoing caſe, till the lung has collapſed; but, that if the patient now attempt to expire, the injured ſide of the thorax muſt continue diſtended, notwithſtanding every effort. However, in general the air makes a way for itſelf through the cellular membrane, and as the paſſage of air into the cavity of the thorax, during inſpiration, is eaſier than the return of that which has been already effuſed into the cellular membrane, this effuſion continues to go on with great rapidity, while the patient lives, ſo as to occaſion what has been termed *ſubcutaneous emphyſema*.

The above writer alſo obſerves, that in the caſe of a wound which ſimply penetrates the cheſt, without hurting the lungs, if the acceſs of air be more free by the wound than by the trachea, more air will enter during inſpiration into the cavity of the thorax than into the lungs; and that if the acceſs of air be, on the contrary, leſs free, then alſo leſs air will enter the thorax than the lungs. However, Dr. Halliday remarks, that in the ſame proportion as air enters into the lungs, or into the cavity of the thorax, it will likewiſe be expelled from theſe cavities during expiration. Hence, air would not accumulate in the thorax, did not the lungs always tend to collapſe from their natural gravitation. Perhaps no author has offered a more accurate and ſpirited deſcription of an emphyſema ariſing from a fractured rib than Mr. John Bell, of Edinburgh. This gentleman remarks, that when a rib is broken, the point of the broken bone is preſſed down upon the ſurface of the lungs, ſo as to lacerate them. It is often from the ſlighteſt and moſt ſuperficial wound of this kind, that the emphyſematous tumour proceeds, the laceration of the lungs extending to ſo inconſiderable a depth in the lungs, that it does not even occaſion the leaſt ſpitting of blood, or any other ſymptom of a deep wound; and Mr. John Bell obſerves, that if the patient die, the wound cannot be ſeen even after diſſection; but can only be diſcovered by inflating the lungs. Yet, ſays this gentleman, the ſurface of the lungs being touched even in this ſlight way, the air eſcapes from them at every inſpiration; the air which is then within the cavity of the thorax is of courſe compreſſed, ſo that at the next expiration this compreſſion muſt force the air either back again into the lungs, or elſe out of the wound in the parietes of the thorax, and thence among the cellular ſubſtance ſurrounding the broken rib. Thus, obſerves Mr. John Bell, in every inſpiration there is a ſuction of ſome air, which is drawn through the wounded lungs, the air expands in the cavity of the thorax, the lung which gave out that air ſubſides again, and lies almoſt entirely quieſcent, partly from the wound in it, which, like a rent in a bladder, prevents it from being inflated, and partly from the preſſure of the air in the cavity, in which there ought to be a vacuum to make the lung expand. Every new inſpiration draws more air from the wounded lung, and every new expiration drives more air out into the cellular ſubſtance. There is no further outlet for the air, which makes its way forwards, and (to uſe Mr. John Bell's expreſſion) undermines the common ſkin with wonderful rapidity. Thus, the emphyſematous crackling tumour appears firſt over the broken rib, or over the wounded point of the thorax; then extends over the whole cheſt, attended with great oppreſſion of the breathing; then over the neck and face, and filling the eye-lids particularly, ſo that the eyes are abſolutely cloſed. Next it ſpreads over the belly, and down the thighs. At laſt, the private parts become enormouſly ſwollen, and no part eſcapes this tumour, except the palms of the hands and ſoles of the feet. More air, ſays Mr. John Bell, is every moment drawn out from the wound of the lungs, and driven under the ſkin; the patient is every moment more and more oppreſſed; till, at laſt, the breathing is quite interrupted, the pulſe flags, the extremities grow cold, and the patient, if he be not relieved by ſome operation, muſt die.

According to the ſame writer, the wounded lungs collapſe, and continue in this ſtate until the breach in them has healed, which happens in a very few days. From the moment when the lungs are wounded, the uſe of the wounded lobe is loſt, ſo that if the right lung be the one injured, the breathing is entirely carried on by the left, only half the quantity of air is inſpired, and the reſpiration is attended with difficulty. Mr. John Bell conſiders this collapſe of the injured lung, which muſt inevitably continue for at leaſt a few days, a chief means of ſafety, at the ſame time that it is a cauſe of diſtreſs. He obſerves, that when the lungs are unfolded their veſſels have their full diameter, they hold their full proportion of blood, and, if they were not collapſed, their wounded veſſels would be in a condition to emit a conſiderable quantity of blood. But, the fact is, when one of theſe organs is wounded, it collapſes towards the ſpine, and can no more be filled than a torn bladder can be inflated. The lung is alſo oppreſſed by whatever air or blood may be effuſed in the cavity of the thorax. The collapſe of the lung cauſes leſs blood to be extravaſated in the cheſt, and leſs to be thrown into the bronchiæ, which latter kind of hemorrhage is even more dangerous than that which takes place in the cavity of the pleura, becauſe it may not only affect the wounded lung, but obſtruct the entrance of air into the other one, ſo as to produce a fatal ſuffocation.

Mr. John Bell very judiciouſly remarks, that, if the injured lung were not to collapſe, it would be difficult to conceive, how the breach could ever be healed; for, the air would be continually ſtreaming through the wound, which becoming alternately dilated and contracted, like that of an artery, could never cloſe. However, ſince the wounded lung lies in a collapſed ſtate, the edges of the wound are in contact with each other. We find by diſſection, that a ſlight effuſion of blood, a degree of livor, a ſwelling, thickening, and inflammation, take place round the wound, and thus, in two days, the breach is cloſed. The lung becomes again entire, and capable of reſuming its functions.

Mr. John Bell alſo takes notice, that the blaſt of air, from a wound in the thorax, is often ſo ſtrong, that at every breath it is capable of extinguiſhing a candle, and ruſhes out with a conſiderable noiſe. This ſtream of air, ſo far from being a ſign of wounded lungs, is often moſt remarkable, when the lungs are abſolutely entire. It is a ſign of a free and open wound in the cheſt; but, by no means of wounded lungs; for whether theſe organs be wounded or not, the air enters ſo freely by the outward wound, when ample and direct, that there is no vacuum formed to give the lung play, and it muſt collapſe, till the external wound has healed. Wounds of the thorax, therefore, are totally different caſes from wounds of the lungs. When the cheſt has a large free opening made into it, it is (as Mr. John Bell deſcribes) like a pair of bellows, having a large air-hole, which admits the air every time the breaſt riſes; and expels it again as often as the breaſt falls down. The air is alternately drawn in, and thrown out at every reſpiration, with a ſtrong blaſt; but, whatever air iſſues through the wound, had been drawn in by the wound, and had never paſſed through the lungs. Hence, when there is a free opening made in the thorax, no vacuum can form ſo as to lead to the expanſion of the lung, and whether entire, or injured, it muſt be in a collapſed ſtate.

We may be convinced, that the lung, on the ſide oppoſite the wound, is adequate to the temporary ſupport of life, by the recollection of ſeveral kinds of caſes. When a large free opening has been made into the cheſt by ſome accident, or by the ſurgeon's knife, the lungs on the injured ſide of courſe collapſe; yet, the patient has often been known to live with tolerable eaſe in this condition, until a perfect recovery has followed. When the right or left lung has been utterly prevented from becoming expanded, in conſequence of the preſſure of air in emphyſema, water in hydrops pectoris, or pus in empyema, the patient has often lived a conſiderable while in this ſtate, and ultimately got well. Perſons have lived ſo long with diſeaſe in the cheſt, that when they have died, and their bodies have been opened, only a ſmall knob, or tubercle of the lungs on one ſide, has been found remaining. See Koelpen de Empyemate Obſervatio, p. 135, 136.

When the lungs are wounded by the point of a broken rib, or when they are injured by a narrow ſtab in the thorax, the air cannot readily eſcape from the cavity of the cheſt, while at every inſpiration more and more is drawn out from the lungs, till at laſt ſuch a quantity accumulates, that it not only oppreſſes the lung, which is on that ſide, but by hindering the free action of the diaphragm, and loading the mediaſtinum, it oppreſſes the other lung alſo. In this manner, the breathing becomes gradually more and more interrupted; the pulſe ſinks; the extremities grow cold; and after great toſſing, and undeſcribable anxieties, the patient dies. All this may happen, even when a part of the air eſcapes through the breach in the pleura coſtalis, ſo as to inflate a great part of the common cellular membrane of the body. See Diſcourſes on the Nature and Cure of Wounds by John Bell, vol. ii.

From what has been ſtated, it muſt be evident, that the emphyſematous ſwelling itſelf, or, in other words, the diffuſion of air in the cellular ſubſtance, is a matter of ſecondary conſequence, and, that the great peril of an emphyſema depends on the manner in which one ſide of the cheſt may become ſo diſtended with air, that the preſſure produced on the diaphragm, mediaſtinum, and oppoſite lung, occaſions a fatal interruption of reſpiration.

However, in caſes in which there is a free and open wound in the parietes of the cheſt, or when the ſurgeon has made an ample and direct inciſion into the thorax, the opening, in fact, does not relieve the lung on the ſame ſide, but the oppoſite one, by obviating the preſſure of any confined air on it. In the mean while, the lung on the wounded ſide lies in a collapſed ſtate, till the wound in it has healed.

It is curious to obſerve, how few of our beſt modern ſurgical writers have had accurate notions concerning emphyſema. Hewſon, Benjamin Bell, and Bromfield, have all fallen into the miſtake of ſuppoſing it poſſible to make the wounded and collapſed lung immediately expand again by exhauſting the air from the cavity of the pleura. Mr. Bromfield writes, "in caſe an opening is made between the ribs, and a cannula introduced, whoſe diameter is larger than the wound of the lungs, the air will be forced out as faſt as it eſcapes from the lungs, therefore the lungs will have room for their *expanſion*," &c. See Chirurgical Caſes and Obſervations.

Mr. Hewſon obſerves, "it is natural to ſuppoſe, that the wound of the pleura and intercoſtals may ſometimes be too ſmall to ſuffer the air to get readily out into the cellular membrane, and to inflate it, but may confine a part of it in the cavity of the thorax, ſo as to compreſs the lungs, *prevent their expanſion*, and cauſe the ſame ſymptoms of tightneſs of the cheſt, quick-breathing, and ſenſe of ſuffocation, which water does." Mr. Hewſon ſeems to have no idea of the danger of ſuffocation proceeding from the preſſure on the oppoſite lung, and though he wrote profeſſedly to recommend paracenteſis thoracis in theſe caſes, he adviſes making a ſmall inciſion, rather than a large one, *leſt the air ſhould enter, and hinder the expanſion of the lungs.* Med. Obſ. and Inq. vol. iii.

Mr. Benjamin Bell has undoubtedly run into moſt ſtrange abſurdities in the deſcription in his Syſtem of Surgery, of plans for expelling the air from the ſurface of the lungs. "While the wound yet remains open," ſays he, "let the patient, in a ſlow gradual manner, make a full *inſpiration*, by which a conſiderable quantity of the collected air will be diſcharged. This being done, the ſkin muſt be inſtantly drawn over the *ſore*, ſo as to cover it completely during *expiration*; and if the wound be moderately opened during *inſpiration*, the whole quantity will be ſoon expelled."

In this paſſage, the author has obviouſly confounded the words expiration and inſpiration, beſides diſplaying ignorance in thinking it practicable to make the collapſed wounded lung riſe up again by ſuch proceedings.

The ſame author remarks: "the other means which we wiſh to propoſe for drawing off air from the thorax, is ſuction; an exhauſting ſyringe may be fitted with ſuch a mouth of ivory or metal, as will allow it to be cloſely applied over the orifice in the pleura:" He adds, that "as much diſtreſs has, on ſome occaſions, enſued from both cavities of the cheſt being at the ſame time laid open, it ought never to be attempted." He afterwards imputes the danger, not to the collapſe of both the lungs, but to the inflammation likely to ariſe from the admiſſion of air into the two cavities of the cheſt at once. The fact is, a free opening made into each ſide of the cheſt at the ſame time would be inſtantly followed by a collapſe of both lungs, and immediate ſuffocation. There would neither be time for any inflammation to ariſe, nor for relieving the patient with exhauſting ſyringes.

There is certainly a poſſibility of making the lungs expand again, by ſyringes, &c. as ſoon as the breach in them has healed, or the injured air-cells have been cloſed with coagulating lymph; but, the propriety and utility of the plan may be juſtly called in queſtion. The introduction of pipes into the cheſt cannot be done without irritation; no more air can eſcape from the lung now the air-cells are cloſed; what is already effuſed in the cheſt will be abſorbed, and the lung expand again, in proportion as this is effected; and ſhould the diaphragm and oppoſite lung ſuffer dangerous preſſure from the large quantity of accumulated air, relief may be derived from making an opening in the diſtended ſide of the cheſt, ſufficient for letting out a certain quantity of the confined air. In this inſtance, a ſmall puncture in the pleura would ſuffice: the caſe is not like ſome others, in which the breach in the lung is not cloſed, and a very free and direct opening is required, in order to let the air eſcape from the thorax, as faſt as it paſſes out of the wound in the lung itſelf. By this ſtep, and no other, can we prevent the ſpreading of the emphyſematous ſwelling over the whole body, and what is of ſtill higher moment, a perilous degree of preſſure on the diaphragm and oppoſite lung.

Some of the moſt remarkable caſes of emphyſema, on record, are related by M. Littre, M. Mery, Dr. Hunter, and Mr. Cheſton, in the Mem. de l'Acad. Royale des Sciences for 1713, Medical Obſervations and Enquiries, vol. ii, and Pathological Enquiries.

With reſpect to the treatment of emphyſema, when the air becomes effuſed in the cellular ſubſtance round a wound, which merely injures the parietes of the cheſt, the beſt plan muſt be to direct the patient to expel as much of the air from the thorax as he can, by making long expirations, the opening being regularly cloſed when the patient enlarges his cheſt in inſpiration. After getting as much air as poſſible out of the thorax in this manner, the edges of the external wound may be carefully brought together, and well covered with adheſive plaiſter, compreſſes, &c. ſo as to prevent the ingreſs of any more air into the cheſt. The emphyſematous ſwelling can now no longer increaſe, or, at all events, can only do ſo as long as whatever air is ſtill in the cheſt continues unexhauſted; and in proportion as it becomes effuſed, or is abſorbed, the lung muſt expand and reſume its function again. In this particular inſtance, as there is no breach in the lung, the practitioner, if he thinks proper, may endeavour to make the viſcus expand again at once, by drawing the air out of the cavity of the pleura with a ſyringe. However, ſince all examples of emphyſema, which are attended with urgent ſymptoms of ſuffocation, are accompanied by a wound or laceration of the air-cells of the lung, we cannot rationally attempt to make this organ immediately expand again by means of ſuction. The thing is not practicable, becauſe how can we exhauſt the air from the cheſt, as long as more is capable of paſſing out of the opening in the lung itſelf. We have likewiſe already explained, that the collapſed ſtate of the injured lung is the moſt favourable for the cloſure of the wound in it, and for the prevention of hemorrhage from its veſſels.

In all conſiderable caſes of emphyſema, the air, effuſed in the cavity of the thorax, and common cellular membrane, is derived from a rent, or wound in the ſubſtance of the lungs. The worſt ſymptoms in theſe inſtances, as we have already repeatedly inſiſted upon, depend on the preſſure of the air confined in the injured ſide of the thorax, on the diaphragm, and oppoſite lung. Both this accumulation of air, and the diffuſion of another portion of it in the cellular texture of the body, are entirely owing to one circumſtance, *viz.* there being no free and direct paſſage through which the air can eſcape outward, as faſt as it paſſes out of the breach in the lung.

The inflation of the external parts with air, a thing which often takes place in an enormous degree, is not itſelf a caſe of urgent danger, and, indeed, it is ſo far a favourable event, as it proves, that the air effuſed from the lung can eſcape from the cavity of the pleura in a certain meaſure. If it could do ſo with ſufficient celerity, no oppreſſion of the diaphragm and oppoſite lung would be occaſioned.

In caſes of emphyſema, Mr. John Bell recommended the following treatment to be adopted. 1ſt. Upon obſerving the crackling tumour begin to form over a fractured rib, ſmall punctures ſhould be made with the point of a lancet, and, if the inſtrument be carried deeply enough, the air will ruſh out in an audible manner. As this air was in the thorax before it came into the cellular ſubſtance, it is plain, that the thorax is ſtill full, and that the lung of that ſide is already collapſed and uſeleſs, and muſt continue ſo for a certain time; that is until the breach in it is cloſed. The purpoſe, therefore, of making theſe ſcarifications, and eſpecially of making them ſo near the fractured part, is not to relieve the lungs, but merely to keep the air from ſpreading more widely beneath the ſkin.

When the emphyſema proceeds from a narrow ſtab in the cheſt, the practice ſhould of courſe be the ſame, in the ſame ſtage of the caſe, or, in other words, at the period when the external emphyſematous ſwelling is in an incipient ſtate. The two examples reſemble each other, inaſmuch as the lungs and pleura coſtalis are wounded in both caſes, and the air, which paſſes through the breach in the pleura, cannot make its way completely outward; but becomes diffuſed in the cellular membrane.

2dly. If, before the ſurgeon arrives, the air ſhould have ſpread to very remote parts of the body, as to the ſcrotum and down the thighs, it will be eaſier, ſays Mr. John Bell, to make ſmall punctures in thoſe parts, in order to let out the air directly, than to preſs it along the whole body, till it arrives at the punctures, made on the cheſt, over the wounded part.

3dly. If, notwithſtanding free punctures, and preſſing out the air in this way, it ſhould be found by the oppreſſion, that either air or blood is accumulating within the cavity of the thorax, ſo as to oppreſs not the wounded lung only, which, from the firſt, is of courſe collapſed and uſeleſs, but, alſo, ſo as to oppreſs the diaphragm and other lung; then a freer inciſion muſt be made through the ſkin and muſcles, and a ſmall one in the pleura coſtalis, in order to let the confined air out of the thorax.

In the courſe of a few days the wound in the collapſed lung becomes cloſed by the adheſive inflammation, in which proceſs the breach in the air-cells is ſhut up with coagulating lymph, and the air can no longer get out of them into the cavity of the cheſt. The air, which is already there, is alternately abſorbed, and the lung, expanding in proportion, reſumes its original functions.

Emphyſema has been known to ariſe from the burſting of a vomica, and ulceration of the ſurface of the lungs; but the air, which eſcapes in this inſtance, cannot find its way into the cavity of the thorax, becauſe the inflammation, which precedes the abſceſs and ulceration of the air-cells, cloſes thoſe which are adjacent, and produces an adheſion of the edges of the vomica, or ulcer, to the inner ſurface of the cheſt, ſo as entirely to ſeparate the cavity of the abſceſs from that of the thorax. We do not know of any example, in which the ſymptoms imputed to the confinement of air in the cheſt, originated in conſequence of ſuppuration and ulceration of the ſurface of the lungs. However, Palfyn, Dr. Hunter, and the author of the article "Emphyſema" in the French Encyclopædia, have ſeen caſes, in which emphyſema has ariſen from abſceſſes of the lungs, attended with adheſion to the pleura, and ulcerations in the ſituation of ſuch adheſion. In theſe caſes, the pus having made its way through the pleura, and intercoſtal muſcles, the air eſcapes alſo through the ſame tract, ſo as to get into the cellular membrane on the outſide of the cheſt.

A certain degree of emphyſema has been obſerved to be occaſionally produced by a violent effort of reſpiration. In the inſtances referred to, the air is ſaid firſt to make its appearance about the clavicles, and afterwards to ſpread over the neck and adjacent parts. The violent efforts of parturition have alſo been remarked to occaſion a ſimilar ſymptom; but without being followed by any bad conſequences. See Medical Communications, p. 176.

In the fourth volume of the Mémoires de l'Academie de Chirurgie, 4to. M. Louis has deſcribed an emphyſema of this latter ſort, which, on account of its cauſe, and the indication which it affords the practitioner, is highly important. M. Louis had occaſion to remark the occurrence in a young girl, who died ſuffocated, from a bean falling into her wind-pipe, and he conſiders the kind of emphyſema in queſtion as a pathognomonic ſymptom of ſuch an accident. If this opinion be correct, a knowledge of the circumſtance muſt be of great importance to the practical ſurgeon; for, if making an opening into the trachea, and attempting to extract the foreign body be delayed, from any doubt concerning the nature of the caſe, the patient will inevitably die of ſuffocation. In the caſe which firſt attracted the attention of M. Louis to the ſubject, the emphyſema made its appearance on both ſides of the neck above the clavicles, and came on ſuddenly, on the third day after the foreign ſubſtance had fallen into the trachea. On examining the body, after death, the lungs and mediaſtinum were alſo found to be in an emphyſematous ſtate. The retention of air by the extraneous ſubſtance produced, according to M. Louis, at every attempt to expire, and, particularly, during the violent fits of coughing, a ſtrong propulſion of this fluid towards the ſurface of the lungs into the ſpongy ſubſtance of theſe viſcera. The air next inſinuated itſelf into the cellular texture, which unites the ſurface of the lung to the pleura pulmonalis; and, by communications from cells to cells, it occaſioned a prodigious ſwelling of the cellular ſubſtance, between the two layers of the mediaſtinum. The emphyſema increaſing, at length made its appearance above the clavicles. This tumefaction of the lungs and ſurrounding parts, in conſequence of air getting into their ſpongy and cellular texture, is an evident cauſe of ſuffocation, and M. Louis obſerves, that the ſwelling ſeems to be ſo natural an effect of the preſence of a foreign body in the trachea, that one can hardly fail to think it an eſſential ſymptom, though no author has made mention of it.

An emphyſema of the head, neck, and cheſt, has alſo been noticed in ſome typhoid fevers. Dr. Huxham relates an inſtance of this ſort, which took place in a ſailor of a ſcorbutic habit. Medical Obſervations and Inquiries, vol. iii. art. 4.

Surgical practitioners have frequent occaſion to remark the occurrence of a partial emphyſema in caſes of gangrene. Emphyſema, ariſing from wounds in the thorax, is very often a caſe, complicated with large extravaſations of blood in the cheſt, and inflammation of the pleura and lungs; circumſtances which muſt greatly increaſe the danger, and ought materially to influence the mode of treatment.

The adheſions, ſo frequently met with between the pleura coſtalis and pleura pulmonalis, muſt obviouſly have the effect of preventing the collapſe of the lung, in circumſtances under which it would otherwiſe happen. Were a wound to enter through the middle of any adherent parts, it is plain that no air could find its way out of the lung into the cavity of the thorax.

EMPHYTEUSIS, in the *Civil and Canon Law*, the letting out of poor barren lands for ever, or at leaſt for a long term of years, on condition of the tenants cultivating, meliorating, or mending them, and paying a certain yearly conſideration.

The word is formed of the Greek, εμφυτευσις, which ſignifies *an engraftment*, and by metaphor, a *melioration* or *amendment*; for as we only graft trees to mend them, ſo a man only alienates his land by emphyteuſis, on condition of having it amended.

Emphyteuſes are a kind of alienations, differing from ſales, in that they only transfer the *dominium utile*, the benefits of the ground, not the property, or fee-ſimple. Among the Romans they were at firſt temporary, afterwards perpetual.

The twentieth canon of the council of Carthage prohibits the biſhops ſeizing the church's emphyteuſis out of the hands of private perſons, unleſs they have been three years without paying rent.

EMPIRE, the territory or extent of land under the command and juriſdiction of an emperor. See EMPEROR.

We ſay the Roman empire, the empire of the Eaſt, the empire of the Weſt, or the weſtern empire, the empire of the Great Mogul, &c.

Antiquaries diſtinguiſh between the medals of the *upper* and *lower*, or *bas empire:* the curious only value thoſe of the upper empire, which commences with Cæſar or Auguſtus, and ends in the year of Chriſt 270.

The lower empire comprehends nearly 1200 years, reckoning as low as the deſtruction of Conſtantinople, in 1453.

They uſually diſtinguiſh two ages, or periods of the lower empire; the firſt beginning where the upper ends, *viz.* with Aurelian, and ending with Anaſtaſius, including about 200 years; the ſecond beginning with Anaſtaſius, and ending with the Palæologi, which includes about 1000 years. See MEDAL.

In ancient hiſtory we read of four great monarchies or empires, *viz.* that of the Babylonians, Chaldeans, and Aſſyrians; that of the Medes and Perſians; that of the Greeks; and that of the Romans. The firſt ſubſiſted from the time of Nimrod, the ſame with Belus, or, as others ſay, from the time of Ninus, the ſon of Belus, who founded it in the year B.C. 2059, according to Blair's tables, to Sardanapalus their laſt king, B.C. 820, and conſequently laſted about 1239 years. But chronologers differ much concerning both the commencement and duration of the Aſſyrian empire. (See ASSYRIA.) The empire of the Medes commenced under Arbaces in the year B.C. 821, and was united to that of the Babylonians and Perſians under Cyrus, in the year B.C. 538, and it cloſed in the 5th year of Darius Codomannus, who was conquered by Alexander B.C. 331. The dominion of Perſia, after the death of Darius, was transferred to the Greeks. The Grecian empire laſted only during the reign of Alexander the Great, beginning in the year B.C. 336, and terminating with the death of this conqueror B.C. 323, his conqueſts being divided among his captains. The Roman empire commenced with Julius Cæſar, when he was made perpetual dictator, after the battle of Pharſalia, in the year of the city 706, 48 years B.C. Some, however, date the commencement of the Roman empire after the battle of Actium, with the firſt year of Auguſtus, A.U.C. 723, B.C. 31. The decline of the Roman empire may be conſidered as principally owing to the deſpotiſm of Severus, and the paſſive obedience of the people. From this period we behold a train of emperors vicious, or impotent, either wilfully guilty, or unable to aſſert the dignity of their ſtation. The empire itſelf gradually decayed, harraſſed on all ſides by powerful invaders, and convulſed by the furious conteſts of domeſtic foes. During the reign of Gallienus, 30 pretenders contended for the ſupreme power, and added all the calamities of civil war to the misfortunes of this devoted empire. The power and influence of the emperors were likewiſe diminiſhed by the adoption of ſeveral colleagues, and by the diviſion of the empire between the two ſons of Theodoſius the Great, A.D. 295. Arcadius was proclaimed emperor of the Eaſt, and Honorius emperor of the Weſt. The weſtern empire contained all Italy, Spain, France, Britain, Germany, Pannonia, and Africa. The eaſtern empire comprehended Aſia the Leſs, Arabia, Syria, Egypt, Lybia, and the ſeveral regions on the Danube. The ſeat of the empire was removed to Byzantium by Conſtantine, in the year of our Lord 328: the Eaſt and Weſt were then united under the title of the Roman empire, till the Romans proclaimed Charlemagne emperor, A.D. 800. From this epocha the Eaſt and Weſt formed two ſeparate empires; that of the Eaſt, governed by Greek emperors, commenced under Nicephorus, A.D. 802, or, rather, was continued; but being gradually weakened, terminated under Conſtantine Palæologus, in 1453, when the Saracens, having ſubdued Syria, Paleſtine, Egypt, Cilicia, and other neighbouring countries, and having ravaged the reſt of the Roman territories in the Eaſt, beſieged Conſtantinople under Mahomet II. and became maſters of it. From this period the city has been the imperial ſeat of the Turkiſh or Ottoman emperors. The weſtern empire, properly ſo called, terminated with Auguſtulus, ſon of Nepos, A.D. 476, but being revived under Charlemagne, it ended with Charles Le Gros, who poſſeſſed all the dominions of Charlemagne, A.D. 887, and it was afterwards known by the appellation of the *empire* or German empire.

Empire, or *the* Empire, uſed abſolutely, and without any addition, long ſignified the empire of Germany, called alſo in juridical acts and laws, the *holy Roman empire*, *S. R. I.* q. d. *ſacrum imperium Romanum*, which conſtituted what was otherwiſe called the *Germanic body*.

The empire had its beginning with the ninth century; Charlemagne being created firſt emperor by pope Leo III. who put the crown on his head in St. Peter's church on Chriſtmas day, in the year 800.

Authors are at a loſs under what form of government to range the empire; ſome ſuppoſe it to have been a monarchical ſtate, becauſe all the members thereof are obliged to aſk the inveſtiture of their ſtates of the emperor, and to take an oath of fidelity to him.

Others maintain that it was a republic, or ariſtocratic ſtate, becauſe the emperor could not reſolve or determine any thing without the concurring ſuffrages of the princes. It is added, that if they required inveſtiture from, and ſwore fealty to him, it was only as head of the republic, and in the name of the republic, and not in his own; juſt as at Venice, every thing is tranſacted in the name of the doge. See Doge.

Laſtly, others will have the empire to have been a monarcho-ariſtocratic ſtate, *i. e.* a mixture of monarchy and ariſtocracy; becauſe, though the emperor in many caſes ſeemed to act ſovereignly, yet his decrees and reſolves had no force, in caſe the ſtate refuſed to confirm them.

In fine, we ſhould rather chooſe to call it an ariſto-democratic ſtate, becauſe the diet, wherein the ſovereignty is lodged, was compoſed of princes, and the deputies of the cities, and was divided into three orders, or bodies, called *colleges*, *viz.* the college of electors, the college of princes, and the college of cities.

We ſay, diet of the empire, circles of the empire, fiefs of the empire, princes of the empire, eſtates of the empire, members of the empire, capitulations of the empire, receſſus of the empire, &c. See College, Diet, Circle, Prince, Capitulation, and Recessus.

The ſtates or eſtates of the empire were of two kinds, *mediate* and *immediate*. The *immediate* ſtates were thoſe who held immediately of the empire, whereof, again, there were two kinds; the firſt, ſuch as had ſeats and voices in the imperial diet; the ſecond, ſuch as had none. The *mediate* ſtates were thoſe who held of the *immediate*.

The ſtates which afterwards compoſed the empire were the princes of the empire, the counts of the empire, the free barons of the empire, the prelates of the empire, the princeſſes or abbeſſes of the empire, the nobles of the empire, and the imperial cities. For an account of the ſubſequent changes which this empire has undergone, ſee Electors, Emperor, and Germany.

EMPIRIC, in *Medical Hiſtory*, from the Greek word ἐμπειρία, *experience*, an appellation aſſumed by a ſect of phyſicians, who contended that all hypothetical reaſoning reſpecting the operations of the animal economy was uſeleſs, and that obſervation and *experience* alone were the foundation of the art of medicine.

The origin of this ſect is variouſly ſtated by different writers of antiquity, who have attributed it to three different perſons. The empiric phyſicians themſelves ſeem to have conſidered Acron of Agrigentum, who was a contemporary and rival of Empedocles, (a pupil of Pythagoras,) in the 70th olympiad, as their founder; and Pliny has aſſerted the ſame opinion, in his ſketch of the hiſtory of medicine. (Nat. Hiſt. lib. xxix. cap. 1.) "Alia factio, ab experimentis ſe cognominans *Empiricen*, cæpit in Sicilia, Acrone Agrigentino, Empedoclis phyſici auctoritate, commendato." This account of the riſe of their ſect was maintained by the empirics, in order to obtain the advantage over the rational or dogmatic phyſicians, who could only date their origin from the time of Hippocrates. But it has been juſtly remarked, that the phyſicians, who lived between the time of Æſculapius, and the period, when philoſophy and reaſoning were applied to medicine, were empirics in fact, though not in name, in conſequence of the rude and imperfect ſtate of the art, and cannot be regarded as ſectaries, ſince all were at that time equally empirical.

The beſt hiſtorians refer the eſtabliſhment of this ſect to a much later period; namely, to about the 123d olympiad (A. C. 260); but they are not agreed as to the individual, who firſt promulgated the doctrine of empiriciſm. Galen and others have aſcribed the origin of the ſect to Philinus of Cos, who was a diſciple of Herophilus, to whom he was ſaid to be indebted for the firſt hints of his ſyſtem. Herophilus was doubtleſs more attentive to the uſe of drugs than any of his predeceſſors, and the empirics directed their views particularly to the diſcovery of medicines: his numerous diſcoveries in anatomy likewiſe led him, and ſtill more his diſciples, to queſtion the value of the reaſoning of their predeceſſors, in whoſe ſtatements of fact they found ſo much error, particularly in regard to the ſtructure of the human body. Little, however, is known with certainty reſpecting this Philinus. Galen quotes him, when writing on the ſubject of the compoſition of medicines; and he is ſaid to have written on the nature of plants, and to have commented on the writings of Hippocrates.

Celſus, however, aſſerts, that Serapion was the firſt who maintained the doctrine, that the application of reaſoning and philoſophy to the art of medicine was of no avail, and confined the ſtudy of it to practice and experience. (De Medicina, Præf.) Serapion was born, and practiſed medicine at Alexandria, and appears to have been contemporary with Philinus, and the diſciples of Herophilus. Galen accuſes him of having ſhewn a contempt for Hippocrates and all his predeceſſors, in his writings, and of praiſing himſelf on all occaſions. (Galen. de ſubſigurat. Empir. Cap. ult.) Apollonius, Glaucias, Heraclides of Tarentum, and others of no ſmall note ("non mediocres viri") followed in the ſteps of Serapion, according to Celſus. Heraclides was one of the moſt famous of the empirics, and appears to have been the firſt to employ that valuable ſubſtance, opium, in the practice of medicine. Many other names are on record, as belonging to this ſect, antecedent and poſterior to Heraclides: one of the lateſt was Marcellus, who lived in the time of Theodoſius, and appears to have held ſome office in the court of that emperor, and was probably therefore a Chriſtian. He has left a treatiſe on medicines, compiled from various writers, and adapted to the cure of all diſeaſes. The art of medicine, indeed, is indebted to the empirical phyſicians for many important additions to the Materia Medica. With reſpect to the doctrines of the ſect, however, and the principles on which they defended themſelves againſt the dogmatics, we have no other accounts, than thoſe which their adverſaries have given, in quoting them with a view to their refutation; all their works upon theſe topics have periſhed. Celſus and Galen have ſtated probably the greater part of the leading points of their tenets.

The *empiric* ſyſtem, as the term imports, was founded altogether upon *experience:* and thoſe, who belonged to this ſect have remarked, that there are three modes by which we learn, from experience, to diſtinguiſh what is advantageous and what is prejudicial, in regard to our health. The firſt of theſe, and the moſt ſimple, ariſes from *accident*. A perſon, for example, having a violent pain in the head, happens to fall, and divides a veſſel in the forehead; and it is obſerved that, having loſt blood, his pain is relieved. Under the ſame mode, they include the experience which is acquired by obſerving the ſpontaneous operations of the conſtitution, where no remedy has been applied, as in the following caſe: a perſon labouring under a fever, finds his diſeaſe mitigated, after a hemorrhagy from the noſe, a profuſe perſpiration, or a diarrhœa. The ſecond mode of gaining experience, is, that, in which ſomething is done by *deſign*, with a view to aſcertain what will be the ſucceſs of it: as, for inſtance, when a perſon, having been bitten by a ſerpent, or other venomous creature, applies to the bite the firſt herb that he finds; or when a man attempts to alleviate the ſymptoms of an acute and burning fever, by drinking as copiouſly as he is able of cold water; or when a perſon tries a remedy, ſuggeſted to him by a dream, as was frequently done in heatheniſh times. The third mode of experimenting, is that which the empirics termed *imitative;* which is purſued in caſes, when, after having remarked the effects reſulting from *accident*, or the ſpontaneous actions of the ſyſtem, on the one hand, or from *deſign* on the other, we make an attempt to accompliſh a ſimilar reſult, by imitating that which was done on thoſe occaſions.

This laſt ſort of experience, they contend, is that which peculiarly conſtitutes the art of medicine, when it has been frequently repeated. They call that *obſervation*, (τήρησις,) or *autopſia* (αὐτοψία,) which each individual ſees himſelf; and uſe the term *hiſtory*, or *record*, (ἱστορία) for ſuch obſervation when committed to writing; that is, the autopſia, or perſonal experience, conſiſts of the obſervations which each perſon has made, by his attention to the progreſs of a diſeaſe, whether in regard to its ſymptoms and changes, or to the remedies employed; while the record is a ſort of narration or regiſter of all that was obſerved by thoſe individuals; which regiſter being completed, (*i. e.* including all the diſeaſes, incident to mankind, and the remedies adminiſtered for their alleviation,) the art of medicine would be eſtabliſhed with a conſiderable degree of certainty. But as new diſeaſes ſometimes occur, in regard to which neither our perſonal experience, nor the obſervations of others, can furniſh us with any aſſiſtance; and we meet with diſorders in particular ſituations, where the means of relief, ſanctioned by experience elſewhere, are not within our reach; we muſt neceſſarily have recourſe to ſome other expedient in order to alleviate the ſufferings of the patient. The empirics were provided againſt this particular difficulty, in what they termed *a ſubſtitution* of ſimilar means, (*tranſitus ad ſimile*, as the Latins have tranſlated it.) This was a new experiment, which they inſtituted, after having compared one diſeaſe with another; or one part of the body with another, of ſimilar ſtructure; or, laſtly, one remedy, the nature of which was aſcertained by experiment, with another which reſembled it. "They tried, for example, in *herpetic* eruptions the remedies which had relieved *eryſipelas;* in the diſeaſes of the *arms*, they employed the expedients which had been practiſed in thoſe of the *legs;* and if they could not procure *quinces*, which are an auſtere fruit, they uſed *medlars*, which are not ſo."

Obſervation, then, *record*, and the *ſubſtitution* of ſimilar means, were the three fundamental reſources of the art of medicine; according to the empirics; and theſe were denominated by Glaucias, and others, the *tripod of medicine* (τρίπους τῶν τριῶν.)

There is obviouſly a great deal of good ſenſe and ſound philoſophy in this doctrine of empiriciſm. It points out the true mode of inveſtigating the phenomena of nature, by unwearied experiment; the mode which Bacon laboured to inculcate on the dogmatiſts, and hypotheſis-mongers of his age, which Newton ſucceſsfully purſued, and which has led the philoſophers of later times to the developement of that fund of natural knowledge in the ſciences of electricity, chemiſtry, mechanical, and every branch of natural philoſophy, by which modern inquiry is diſtinguiſhed. Compared with this ſpecies of inveſtigation, how futile are the ſpeculations, miſnamed philoſophy in the ſchools, relative to elements, and eſſences, which had no exiſtence, except in the imagination of the diſputants. For it muſt be obſerved, that the ancient empirics did not diſregard the dictates of reaſon and reflection; they only deprecated the application of them to circumſtances out of the reach of the ſenſes, and beyond the ſcope of experiment. Thoſe miſchievous principles and practices, which their ſucceſſors or at leaſt thoſe who have ſubſequently aſſumed the title, have made the refuge of ignorance and craft, cannot be alleged againſt them. This is evident, from the clear and explicit ſtatement of their tenets, which Celſus has tranſmitted to us: in order to underſtand which, it will be neceſſary to attend to the tenets of their opponents, the rationaliſts or dogmatics, as ſtated by the ſame elegant writer.

The dogmatic phyſicians maintained the neceſſity of a knowledge of the four following ſubjects, in order to be able to cure diſeaſes; namely, 1, of the occult and eſſential cauſes of diſeaſe; 2, of the evident cauſes; 3, of the natural actions of the conſtitution, (or phyſiology;) and, laſtly, of the internal parts, or anatomy. 1. By the *occult* cauſes, they meant the eſſential principles of the conſtitution, or of animal life, under its various conditions of health and diſeaſe. And they held, that it was impoſſible to cure diſeaſe, if we are ignorant of the circumſtances in which it conſiſts; for that different methods of cure muſt neceſſarily be requiſite, if a redundancy or deficiency of the *four elements* were the eſſential cauſe of diſeaſe, according to the hypotheſis of ſome philoſophers; or if all diſeaſe conſiſt in depravations of the fluids, as was the opinion of Herophilus; or, in diſordered reſpiration, as Hippocrates imagined; or in the paſſage of the blood into thoſe veſſels, which naturally convey air, cauſing inflammation, and that inflammation exciting the commotion obſerved in fever, according to the ſuppoſition of Eraſiſtratus; or in the obſtruction of the inviſible pores, by the corpuſcles, or atoms, as Aſclepiades contended. Againſt this ſyſtem of reaſoning by hypotheſis, beyond the bounds of experimental inquiry, the empirics objected upon the moſt irrefragable principles. "The attempt," ſay they, "to ſcrutinize the occult principles of animal life is fruitleſs; for 'nature is incomprehenſible:' we may aſcertain *what* ſhe performs; but *how* ſhe performs it, is to us inſcrutable. And the very diſſenſions among the theoriſts, and the difference of their accounts of thoſe operations, evince the inſcrutability of the ſubject. They cannot all be right; and why ſhould we believe the ſtatement of one, rather than that of another? Why is Hippocrates more entitled to credit than Herophilus, or Herophilus than Aſclepiades? It is obvious that we cannot decide in favour of the opinion of any of them, either from their arguments, or their practical authority; for the arguments of each may be ſufficiently plauſible and conſiſtent with probability; and their practice may have been equally ſucceſsful. Indeed this very fact, that phyſicians of the moſt oppoſite theoretical opinions have equally ſucceeded in reſtoring health to the ſick, proves the independence of the art of medicine upon ſuch diſquiſitions, and that their ſucceſs is to be aſcribed to their principles of cure having been deduced, not from their ſpeculations about occult eſſential cauſes, nor even about the natural actions, but from experiment, from what actual practice had taught them. And ſuch is the caſe in all other arts. The huſbandman and the pilot are not qualified for their reſpective occupations by theory and diſcuſſion, but by practice and experiment. Indeed if reaſoning could enable a perſon to cure diſeaſes, the philoſophers would neceſſarily be the beſt phyſicians; whereas, we obſerve that they are gifted with an abundance of words, but poſſeſs very little ſkill in the art of healing."

2. With reſpect to the *evident* cauſes, the dogmatiſts underſtood, by that term, the obvious exciting cauſes of diſeaſes, ſuch as heat and cold, faſting and exceſs in eating, &c., to the operation of which diſeaſes are often obſerved immediately to ſucceed. The empirics admit the utility and importance of attending to theſe cauſes; but they contend that, however obvious they may be in many inſtances, the method of cure is nevertheleſs not apparent from them, as in ophthalmia, or in a wound; but is aſcertained only from experience.

3. The *natural actions* of the body, a knowledge of which the dogmatiſts maintain to be abſolutely neceſſary to the phyſician, are thoſe operations of the conſtitution, which the moderns comprehend under the term phyſiology; namely, the nature of reſpiration; of the concoction or digeſtion of our food and drink, and its diſtribution to the different parts of the body, which it nouriſhes; of the "riſe and fall" of the arteries; of ſleeping and waking, &c. "Without an acquaintance with the cauſes of theſe actions," ſay the rationaliſts, "it muſt be impoſſible for any one either to ſuppreſs incipient diſeaſes, or to cure them when they are completely eſtabliſhed." But of all theſe actions, they deem the digeſtion of the food the moſt important, and inſiſt more particularly upon the neceſſity of its being underſtood. But in this point again there is great diſſenſion among them: ſome of them, following the hypotheſis of Eraſiſtratus, maintain that the food is concocted by mechanical attrition; others, after Pliſtonicus, the diſciple of Praxagoras, aſſert that digeſtion is produced by the putrefaction of the food; while others prefer the opinion of Hippocrates, and contend that it is effected by heat. The diſciples of Aſclepiades, again, affirm that all theſe hypotheſes are idle and futile, for that there is no ſuch thing as concoction, but that the alimentary matter, crude as it is received, is diſtributed through the whole body. Various as theſe opinions are, however, they do not diſpute the neceſſity of accommodating the food of the ſick to the nature of the function; that is, if the concoction be the reſult of attrition, then ſuch food ſhould be ſelected as is moſt eaſily broken down; if it be effected by putrefaction, then ſuch food is to be choſen as is moſt readily putreſcent; if by heat, ſuch as moſt effectually cheriſhes heat: but if there be no ſuch proceſs as that of concoction, then all theſe kinds of aliment are improper, and ſuch only ſhould be taken as moſt completely reſiſts all change. In the ſame manner, they contend, when a difficulty of breathing occurs, or a morbid degree of ſleep or watchfulneſs, that phyſician will be the moſt capable of curing them, who is acquainted with the nature of theſe functions.

Againſt this doctrine of the dogmatiſts, it is evident that the arguments of the empirics were equally concluſive, as againſt their preceding hypotheſes, reſpecting the occult cauſes. Their ſtatements, that the very difference of the theories of the dogmatiſts implies their want of foundation, and that the mode in which nature operates being incomprehenſible, we muſt be content with learning what ſhe operates, are obvious refutations of the futility of theſe, and indeed of all other hypotheſes. "It is of no importance," ſay the empirics, "to inquire in what manner the diſtribution of the aliment through the body is accompliſhed; our only uſeful inquiry is, what ſort of aliment is moſt eaſily diſtributed; and whether digeſtion is performed by heat or putrefaction, or whether it is not a digeſtion, but a diſtribution only, is altogether immaterial, provided we know, from experience, what is moſt eaſy of digeſtion, or the contrary. For," they continue, "the art of medicine, even in its infancy, was not deduced from ſuch hypothetical reaſoning, but from experiments. Whence it was obſerved, among thoſe who were ſick, and without phyſicians, that ſome, prompted by appetite, had immediately taken food at the beginning of their illneſs; while others, loathing victuals, had faſted altogether; and that the diſeaſe in thoſe who had abſtained from food had been alleviated. It would be remarked, too, that ſome took food in the paroxyſm of a fever, others a little before it came on, and others again after its remiſſion; and that it would agree the beſt with thoſe who ate after the removal of the fever. In like manner, it would be ſeen, that thoſe who took food freely in acute diſeaſes, ſuffered an aggravation of their ſymptoms, while the abſtemious would not thus ſuffer. Theſe and ſimilar circumſtances, occurring daily, would be noted by diligent obſervers; and what had been ſeen to ſucceed moſt generally, that they afterwards preſcribed to the ſick. Such was the origin of the art of medicine, which, in conſequence of the recovery of ſome, and the death of others, taught us to diſcriminate the uſeful expedients from thoſe that were pernicious: and when remedies were diſcovered by ſuch experiments, then men began to reaſon about their operation; for the art of employing remedies was obviouſly not the reſult of reaſoning, but explanatory hypotheſes were ſought for after the remedies were aſcertained.

4. The dogmatiſts contend, in the laſt place, that as pains and various diſorders attack the *internal parts*, no perſon, in their opinion, can apply proper remedies to them, when diſeaſed, if he is ignorant of their ſituation and appearance. Hence, they affirm, that it is neceſſary to diſſect the bodies of the dead, and to examine the viſcera and inteſtines: and they extol the method of Herophilus and Eraſiſtratus, who procured criminals out of priſon, by royal permiſſion, and, having diſſected them alive, contemplated, even while they were breathing, the parts which nature had before concealed; and remarked their poſition, colour, figure, ſize, arrangement, ſoftneſs, hardneſs, ſmoothneſs, and connection, as well as their proceſſes and depreſſions, or what is inſerted into and received by each part. "For," ſay they, "when any internal pain occurs, the ſeat of that pain cannot be aſcertained by one who is ignorant of the ſituation of the viſcera and inteſtines; nor can he cure any part diſeaſed, who does not know what the part is. Beſides, if the viſcera happen to be expoſed in conſequence of a wound, if the obſerver be unacquainted with the natural appearance of each part, he cannot diſcover what is found, and what injured or corrupted, and therefore is not qualified to cure that part which is diſeaſed. Even external remedies are applied with much more judgment by one who knows the ſituation, figure, and ſize of the internal parts. Nor can it be juſtly deemed cruel (although it is generally ſo repreſented) to put a few guilty individuals to torture, with a view to aſcertain means of relief for all the innocent among mankind in all ſucceeding ages.

To theſe arguments the empirics reply, that "the preceding doctrines of the dogmatiſts were only idle and frivolous, but in this there is the addition of exceſſive cruelty: for what can be more cruel than to cut open the abdomen and cheſt of living men, and thus to render that benign art, which is the guardian of the health of mankind, the inſtrument of torture, and that of the moſt atrocious kind? more particularly when it is conſidered, that ſome of the information, which is ſought after with ſo much barbarity, cannot be thus acquired at all, and that the reſt may be aſcertained without committing murder. For the colour, ſmoothneſs, ſoftneſs, hardneſs, and other ſuch qualities, are not the ſame in the body, when diſſected, as when it was found: even in bodies that have ſuffered no violence, theſe qualities externally are often changed by fear, grief, hunger, indigeſtion, fatigue, and a thouſand other inconſiderable affections. Whence it is ſtill more probable, that the internal organs, which are ſtill more delicate than the external, and to which even expoſure to the light is new, muſt be changed by the ſevereſt wounds, or rather by ſuch fatal mangling. Nothing can be more abſurd than to ſuppoſe that appearances are the ſame in a dying man, nay, in one already dead, as during life. The abdomen, indeed, may be opened, while a man yet breathes; but no ſooner does the knife reach the thorax, and divide the tranſverſe ſeptum, which ſeparates the upper cavity from the lower, (which the Greeks call the *diaphragm*, διαφραγμα,) than he immediately expires: it is, therefore, the præcordia and viſcera of a dead man which alone the butchering phyſician brings to his view; and which neceſſarily have the appearance of the organs of the dead, and not of thoſe of the living. Thus all that is gained by the phyſician is the opportunity of committing a barbarous murder, and not that of witneſſing the condition of the viſcera in a living man. If, however, any information can be obtained, as to the appearances of the internal parts while the individual yet breathes, accident often gives the practitioner opportunities for ſuch obſervation: for it frequently happens that a gladiator in the *arena*, a ſoldier in battle, or a traveller attacked by robbers, is wounded in ſuch a manner as to expoſe ſome internal organ to view; whence a ſagacious phyſician will learn the ſituation, poſition, connection, figure, and other circumſtances belonging to each, while he is endeavouring to relieve, and not to murder the patient; and thus will acquire, through compaſſion, that knowledge which others have obtained by the moſt horrid cruelty. Moreover, it is clear, from the arguments already ſtated, that it is not neceſſary to mangle even dead bodies; which, though not cruel, is loathſome to the ſight, as are moſt of the circumſtances connected with the dead; and whatever can be learned, reſpecting the living, may be acquired during the treatment of their diſeaſes and wounds." See Celſus, De Medicina, in Præf.

The concluding obſervations, which deny the neceſſity of anatomical knowledge, acquired by the diſſection of dead bodies, appear to be the only point in the tenets of the empiric phyſicians which is liable to diſpute. But even in this point, we are ſatisfied, there is a great portion of truth, ſo far as relates to the knowledge and treatment of thoſe internal diſeaſes, to which the knife of the ſurgeon cannot reach; for the knowledge of the appearances and connection of the viſcera does not enable us to ſuggeſt the practical means of relief, when they become diſeaſed: experience and obſervation alone, as the empirics contend, have taught us to apply the remedies. See an Eſſay on the Importance of Anatomical Knowledge to Medicine, in the Edinburgh Med. and Surg. Journal for Jan. 1809.

After having thus ſtated the doctrines of the empiric phyſicians, in oppoſition to thoſe of their opponents, Celſus has ſubjoined a ſenſible and judicious criticiſm reſpecting the merits of both. But this is not the place to enter more fully into the ſubject; we muſt therefore refer thoſe, who wiſh for the opinion of that claſſical phyſician, to his work already quoted.

There is one point, which could not be well introduced under any of the preceding heads, which the dogmatiſts conſtantly threw out againſt the empirics, namely, that *new* diſeaſes occaſionally occur, for the cure of which, conſequently, practice and experience have afforded no rules or information; whence, they ſay, it is neceſſary to inveſtigate their cauſes, both evident and occult, without a knowledge of which no mortal can find out why one curative expedient ought to be adopted rather than another. But the reply of the empirics to this point is not leſs accurate and ſatisfactory than in the preceding parts of the diſpute. "New diſeaſes," they ſay, "requiring new remedies, ſeldom if ever occur; but if any unknown diſorder ſhould appear, the phyſician would not require the hypothetical doctrines about occult cauſes to direct him in his method of treatment: he would immediately obſerve to what known diſeaſe it was moſt nearly allied in its nature and ſymptoms, and employ the remedies which experience had ſhewn to be ſucceſsful in the ſimilar malady; and by ſuch reſemblance he would be able to diſcover a proper remedy." Celſus.

It is evident, then, that both the dogmatic and empiric phyſicians appealed to experience, and that neither excluded altogether the dictates of reaſon and reflection. The principal difference in their tenets appears to have conſiſted chiefly in this: that the empirics reaſoned only from the facts aſcertained by obſervation, without attempting to explain their eſſential and inſcrutable nature by hypotheſes; and that the latter ſpeculated upon the mode and nature of every action and phenomenon in the animal body, and took theſe ſpeculations as the baſis of their reaſoning:—an error in the inveſtigation of nature, which, as we have before ſaid, was ſo well expoſed by lord Bacon, in modern times; and which was practically illuſtrated in the triumph of Newton's *empiric* doctrines, over the hypotheſes of Des Cartes.

No longer engaged in ſtudying ſyſtems, and averſe to ſpeculation, even in regard to the ſymptoms of diſeaſes, the empirics exerted their whole faculties in inveſtigating the power of medicinal ſubſtances, which laid the foundation of their pre-eminence in pharmaceutical ſkill, and gradually effected thoſe changes in the art of medicine which ſubſequently occurred. The properties of the productions of nature, eſpecially of the vegetable world, were extenſively examined; and the inſtruments of the phyſician, by which he could influence the functions of the living body, were greatly multiplied. It is chiefly to the induſtry of the ancient empirics that we are indebted for the introduction, or rather for the full knowledge, of ſedative and narcotic remedies; on the liberal uſe of which probably depended the ſuperior reputation acquired by ſome of them over their more cautious antagoniſts. Of this ſuperiority, a ſingular inſtance occurs in the many exiſting teſtimonies to the fame of Heraclides of Tarentum, before mentioned, who is recorded as the moſt ſucceſsful phyſician in any age or country of the world.

It is eaſy to ſee, however, that this direction of medical inquiry, given by the empiric phyſicians, to the diſcovery of the qualities of medicinal ſubſtances, or drugs, would in all probability lead to many abuſes and evils. Experiment of this ſort being much eaſier, at leaſt when careleſsly made, than that unremitting and accurate obſervation of the phenomena of diſeaſes, which alone can conſtitute the ſcientific phyſician, the ignorant and idle would content themſelves with pharmaceutic experiments, and neglect the taſk of pathological inveſtigation; and ſelfiſh craft and diſhoneſty would ſoon learn to impoſe on the credulity of the people, in the adminiſtration of ſecret remedies, when the uſe of a particular drug, and not the general treatment of a diſeaſe, was ſuppoſed to be the eſſence of medicine. Hence it actually happened, even in the early ages of phyſic, that theſe ignorant and illiberal pretenders to *panaceas*, and infallible remedies, who did not know one diſeaſe from another by its ſymptoms, appeared in Egypt, Greece, and Arabia, and were much complained of by their more rational contemporaries. In all ſucceeding ages, the race of theſe illiterate pretenders has been multiplied, under the abuſed name of *empirics*. In our own time, indeed, while a college of phyſicians, conſtituted by royal and parliamentary authority, exiſts in the metropolis, for the regulation of the practice of medicine, and the prevention of the miſchiefs occaſioned by noſtrum-mongers, and pretenders of all kinds, *quackery* thrives, unmoleſted by the college, and ſanctioned, licenſed, and protected by patent, on the part of government, to an extent heretofore unexampled. Le Clerc Hiſt. de la Med. Schulzii Hiſt. Med. Celſ. in Præf. Galen, Loc. Cit. Walker's Mem. of Medicine.

Empiric, in *Modern Medicine*, is applied to a perſon, who ſells or adminiſters a particular drug, or compound, as a remedy for a given diſorder, without any conſideration as to the variations of that diſorder, in its different ſtages, or degrees of violence, or as it occurs in different conſtitutions, climates, or ſeaſons, or in perſons of different age, ſex, ſtrength, &c. Such a practice implies a total ignorance of the nature of the human conſtitution, both in health and diſeaſe; and therefore is generally found to be the reſort of the illiterate and ſelfiſh, not to ſay diſhoneſt, part of mankind. See the preceding article. See alſo Quack.

EMPIS, in *Entomology*, a genus of dipterous inſects. The mouth is furniſhed with an inflected ſucker and proboſcis; ſucker with a ſingle-valved ſheath and three briſtles; feelers ſhort and filiform; antennæ ſetaceous. Theſe are carnivorous, and ſubſiſt on flies and other ſmall inſects, which they ſeize with their feet, and pierce with their roſtrum, to ſuck the blood and juices of their body. Some of the ſpecies are found on flowers, in the winged ſtate. None of the larvæ are known.

Species.

Borealis. Black; wings ſubrotund and ferruginous-brown. Linn.

Inhabits Sweden, Britain, and various other parts of Europe, and is often ſeen in ſwarms in the air, like the gnat, on a ſtill evening, about ſun-ſet.

Pennipes. Black, with the poſterior legs long and feathered. Fabr. *Aſilus pennipes*, Scop. Ent. Carn. 994.

Found in Europe, on the geranium ſylvaticum and cardamine pratenſis. A ſuppoſed variety is deſcribed by Linnæus, which has the four poſterior thighs feathered, and the wings brown, with a black rib.

Marginata. Black; wings white, with black margin. Fabr.

A ſmall ſpecies, found in Saxony.

Maura. Black; ſhanks of the fore-legs thick and ovate. Fabr.

Inhabits environs of Hamburgh, about ſtagnant waters.

Livida. Livid; thorax pale-green, with three black lines; baſe of the wings and legs ferruginous. Fabr.

Frequent on the flowers of the cow-parſnip (heracleum ſphondylium) in Europe. The wings are oblong, and veined with fuſcous.

Ciliata. Blackiſh; wings with fuſcous rib; legs black, four poſterior ones feathered. Fabr.

Inhabits Europe, and in ſize reſembles the laſt. The head is black, with a teſtaceous proboſcis; thorax hairy.

Cinerea. Cinereous; thorax immaculate; legs pale; wings at the tip browniſh. Fabr.

Inhabits Sweden, on umbellate flowers.

Maculata. Cinereous; ſnout, ſides of the abdomen, and legs teſtaceous; wings ſpotted. Fabr.

Native of Italy. The thorax is cinereous, with faint lines; legs teſtaceous, with black claws; abdomen with a teſtaceous line on each ſide.

Stercorea. Teſtaceous, with a dorſal black line; wings reticulated. Linn. Fn. Suec.

On umbellate flowers, in Europe.

Minuta. Black; legs teſtaceous; wings white. Fabr.

Inhabits Denmark, on fungi. Small.

Crassipes. Black; all the ſhanks with a long thick joint; wings white, lower half of the outer margin black. Schranck.

Very ſmall, and inhabits Auſtria.

Rufipes. Black, and ſomewhat cinereous, legs ferruginous. Linn.

Native of Europe.

Quadrilineata. Black, and ſomewhat greyiſh;

thorax with four lines; abdomen cylindrical, with the tip inflected. Linn.

Inhabits Europe.

TRILINEATA. Cinereous; thorax with three black impreſſed lines; wings white; legs pale-yellow. Linn.

Abdomen ſometimes yellow, ſometimes fuſcous. This and the three following ſpecies inhabit Europe.

NIGRICUS. Cinereous; thighs black; ſhanks and wings ferruginous. Linn.

GIBBOSA. Fuſcous; thorax gibbous; abdomen thin; wings ſpotted; ſhanks and ends of the legs white. Linn.

FUSCIPES. Brown-cinereous; wings white; legs livid; feet fuſcous. Linn.

LEUCOPTERA. Thorax cinereous; abdomen black; wings white; legs livid. Linn.

EMPLASTICS, in *Pharmacy*, are ſalves, or medicines, which ſtop up and conſtipate the pores of the parts they are applied on; otherwiſe called *emphractics*.

The word is formed from the Greek, *εμπλασσειν*, *to ſtop up*.

Such are fats, mucilages, wax, the whites of eggs, &c.

EMPLASTRA AMYNTICA. See AMYNTICA.

EMPLASTRUM, popularly called *plaſter*, a medicine of a ſtiff, glutinous conſiſtence, compoſed of divers ſimple ingredients, ſpread on leather, or linen, and applied externally.

The word is formed from the Greek, *εμπλαττω* or *εμπλασσω*, *to put in a maſs*, or *to ſmeer over*, becauſe the emplaſter is made of divers kinds of ſimple drugs, worked up into a thick tenacious maſs; or becauſe it covers over the piece of leather or linen to be applied on the part affected.

Emplaſters are made up in a ſtrong ſolid body, that by remaining a long time on the part, the medicinal ingredients they are chiefly compoſed of, may have time enough to produce their effect.

The drugs uſed to give a body and conſiſtence to emplaſters, are uſually wax, pitch, gums, fats, litharge, and other preparations of lead.

There are emplaſters of divers kinds, and uſed with divers intentions; ſtomachic emplaſters; cephalic, ſtyptic, hepatic, diaphoretic, reſolutive, deterſive, emollient, incarnative, aſtringent, conglutinative, &c. emplaſters.

In the preſcription of extemporaneous plaſters, the greateſt regard is to be had to that particular conſiſtence which the part can moſt conveniently bear, whereupon the application is to be made. Thus, plaſters to the breaſt and ſtomach, eſpecially in the intention of emollients or diſcutients, ſhould be yielding and ſoft, as in the officinal emplaſtrum ſtomachicum; but to the loins, or any of the limbs, where warm diſcutients and ſtrengtheners are to be applied, an higher and more adheſive conſiſtence is to be ſought for. The emollient plaſters likewiſe ſhould be laid on thick, and frequently repeated, if the ſymptoms continue, becauſe their better parts are ſoon ſpent. Diſcutients alſo applied to hard tumours, require repetition; but the ſtrengtheners, which are purpoſely contrived of a ſtrong adheſive conſiſtence, are permitted to lie on till they grow dry, and come off ſpontaneouſly. In ſome flatulent tumours, where a plaſter alone will not prevail, they are at intervals taken off, and diſcutient fomentations or lotions made uſe of; ſuch as are compoſed of bitters, carminatives, comprehending alſo lixivial ſalts or alkaline ſpirits.

EMPLASTRUM *Adhæſivum*, *Adheſive Plaſter*, now called "Emplaſtrum lithargyri cum reſinâ," or "litharge-plaſter with reſin," is compoſed of three pounds of litharge or common plaſter, with the proportion of half a pound of yellow reſin; and is prepared by melting the litharge plaſter with a ſlow fire, and mixing the powered reſin. The black ſticking-plaſter, called the lady's court-plaſter, is formed by diſſolving twelve ounces of the gum benjamin in twelve ounces of rectified ſpirit of wine, and ſtraining the ſolution. In a ſeparate veſſel, diſſolve a pound of the beſt iſinglaſs in five pints of pure water; and after ſtraining this ſolution, mix it with the former, and let them ſtand in a narrow veſſel, that the groſſer parts may ſubſide: when the liquor is cold, it will become a jelly, which will melt near the fire when it is to be ſpread. This quantity will be ſufficient for ſpreading on ten yards of half-yard wide ſilk; in order to which, the ſilk muſt be ſtretched in a frame, and the mixture may be ſpread upon it with a ſpunge or bruſh, which ſhould be done near a fire. As each ſpreading dries, it muſt be repeated to the tenth or twelfth time, and then touched lightly with a bruſh to give it a gloſs. The following more ſimple preparation may be ſubſtituted for the former; diſſolve a pound and a quarter of fine iſinglaſs in five pints of water, and before it cools ſpread it on ſilk in the manner above directed.

EMPLASTRUM *ex Ammoniaco cum Mercurio*, now called "Emplaſtrum ammoniaci cum hydrargyro," a form of medicine, ordered to be prepared in the following manner.

Take gum ammoniacum, ſtrained, a pound; purified quickſilver, three ounces by weight; ſulphurated oil, one dram by weight, or q. ſ. Rub the quickſilver with the ſulphurated oil till the globules no longer appear; then add by degrees the gum ammoniac melted, and almoſt cooled again, and make the whole into a plaſter.

This plaſter is recommended in pains of the limbs, ariſing from a venereal cauſe. Indurations of the glands, and other violent tumours, are likewiſe found ſometimes to yield to it.

EMPLASTRUM *Anodynum*, *Anodyne Plaſter*, is prepared by melting an ounce of the adheſive plaſter; and, whilſt it is cooling, mixing with it a dram of powdered opium, and the ſame quantity of camphor previouſly rubbed up with a little oil. This plaſter gives relief in acute pains, eſpecially of the nervous kind.

EMPLASTRUM *Attrahens*, *the Drawing Plaſter*, now "Emplaſtrum ceræ compoſitum," a plaſter ordered to be now made in this manner: take yellow wax and prepared mutton ſuet, of each three pounds; and yellow reſin, one pound: melt all together, and ſtrain the mixture while it is hot.

EMPLASTRUM *Cephalicum*, or "Emplaſtrum picis Burgundicæ compoſitum," is compoſed of Burgundy pitch, two pounds; ladanum, one pound; yellow reſin and yellow wax, of each four ounces by weight; and expreſſed oil of nutmeg, one once by weight: to the pitch, reſin, and wax, melted together, add firſt the ladanum, and then the oil of nutmeg.

EMPLASTRUM *Commune*, or "Emplaſtrum lithargyri," litharge plaſter, a name given to what has been long called *diachylon-plaſter*. It is ordered to be made of a gallon of oil of olives, and five pounds of litharge in very fine powder, boiled together on a ſlow fire, with about a quart of water, to keep them from burning, till they are perfectly mixed, and have the conſiſtence of a plaſter.

This plaſter is generally applied to ſlight wounds and excoriations of the ſkin; it keeps the part ſoft and warm, and defends it from the air, which is all that is neceſſary in ſuch caſes.

EMPLASTRUM *Commune cum Mercurio*, or "Emplaſtrum lithargyri cum hydrargyro," is made in the ſame manner as the ammoniacum-plaſter with quickſilver, of litharge-plaſter, one pound; purified quickſilver, three ounces by weight; and ſulphurated oil, one dram by weight, or q. ſ.

Emplastrum *é Cymino*, or "Emplaſtrum cumini," is compoſed of cummin, caraway, and bay-berries, of each three ounces by weight; Burgundy pitch, three pounds; and yellow wax, three ounces by weight. Let the pitch be melted with the wax; powder the reſt, and mix all together.

Emplastrum *Gummi*, *Gum Plaſter*, now called "Emplaſtrum lithargyri compoſitum." Take of the common or litharge plaſter, three pounds; ſtrained galbanum, eight ounces by weight; common turpentine, ten drams by weight; and frankincenſe, three ounces by weight. Melt the galbanum with the turpentine, and mix with them, firſt, the powdered frankincenſe, and then the litharge plaſter, previouſly melted with a ſlow fire. This is uſed as a digeſtive, and for diſcuſſing indolent tumours.

Emplastrum *Roborans*, the *Strengthening-Plaſter*, now called "Emplaſtrum thuris compoſitum," or compound frankincenſe plaſter, is ordered to be made thus: take of the common or litharge-plaſter, two pounds; of frankincenſe, half a pound; and dragon's blood, three ounces by weight: melt the plaſter, and then add to it the other ingredients in powder.

Emplastrum *Saponis*, *Soap-Plaſter*, is made by mixing half a pound of ſoap with three pounds of melted litharge-plaſter; and boiling them to the conſiſtence of a plaiſter.

Emplastrum *Stomachicum*, *Stomach-Plaſter*, or "Emplaſtrum ladani compoſitum," is compoſed of ladanum, three ounces by weight; frankincenſe, one ounce by weight; cinnamon, powdered, expreſſed oil of nutmeg, of each half an ounce by weight; and oil of ſpearmint, one dram by weight. To the melted frankincenſe add, firſt, the ladanum ſoftened by heat, and then the expreſſed oil of nutmeg. Mix theſe and the cinnamon with the oil of mint, and beat them together in a warm mortar. Let it be kept in a cloſe veſſel. An ounce or two of this plaſter, ſpread on ſoft leather, and applied to the region of the ſtomach, will be of ſervice in flatulencies, ariſing from hyſteric and hypochondriac affections.

Emplastrum, *Veſicatorium*, *Bliſtering-Plaſter*, or "Emplaſtrum cantharidis," is formed by melting two pounds of plaſter of wax, and half a pound of prepared hog's lard; and a little before they coagulate, ſprinkling one pound of cantharides, finely powdered. In order to render bliſtering-plaſters efficacious, care ſhould be taken that the flies be good, freſh powdered, and the powder fine; and that the plaſter ſhould neither be made in too great quantity at once, nor ſpread with a ſpatula too much heated. See Blister.

EMPLEURUM, in *Botany*, from εν, *in* or *upon*, and πλευρα, the *ſide*, alluding to the lateral inſertion of the ſtigma upon the germen. Soland. in Ait. Hort. Kew. v. 3. 513. Schreb. 812. Willd. Sp. Pl. v. 4. 333. Mart. Mill. Dict. v. 2. Juſſ. 298. Claſs and order, *Monoecia Tetrandria.* Nat. Ord. *Rutaceæ*, Juſſ.

Gen. Ch. Male. *Cal.* Perianth of one leaf, bell-ſhaped, four-cleft, permanent. *Cor.* none. *Stam.* Filaments four, thread-ſhaped, equal, ſimple, longer than the calyx, a little ſpreading; anthers erect, oblong, obtuſe, ſomewhat quadrangular, of two cells, each burſting by a lateral fiſſure. Abortive germen ſometimes preſent. Female on the ſame plant. *Cal.* as in the male. *Cor.* none. *Piſt.* Germen ſuperior, oblong, compreſſed, of one cell, terminated by an erect leafy appendage; ſtyle none; ſtigma placed on a lateral tooth at one edge of the germen, erect, cylindrical, ſmooth, deciduous. *Peric.* Capſule oblong, compreſſed, crowned with a leafy oblique appendage, of one cell, burſting at its ſtraighteſt edge. *Seed* ſolitary, oblong, inſerted laterally, encloſed in a bivalve, elaſtic, rigid arillus.—Very rarely two capſules are ſaid to be found in one calyx.

Eſſ. Ch. Male, Calyx four-cleft. Corolla none. Sometimes with the rudiment of a germen. Female, Calyx four-cleft, inferior. Corolla none. Stigma cylindrical, ſtanding on a lateral tooth of the germen. Capſule beaked, of two valves. Seed ſolitary, with an elaſtic arillus.

E. *ſerrulatum.* Soland. in Ait. Hort. Kew. v. 3. 340. Sm. Exot. Bot. v. 2. 7. t. 63. (Dioſma unicapſularis; Linn. fil. in Suppl. 155. D. enſata; Thunb. Prod. 43.) This is the only ſpecies hitherto obſerved. Native of the Cape of Good Hope, where Thunberg, Maſſon, and others have gathered it. Maſſon ſent it to Kew in 1774. It requires the ſhelter of a green-houſe, and the ſame treatment as other Cape plants of the Rutaceous order, *Dioſma*, *Erioſtemon*, &c. but is leſs ornamental than moſt of them, on account of the want of petals. The *ſtem* is ſhrubby, and much branched. *Leaves* ever-green, ſmooth, ſhining, alternate, almoſt ſeſſile, linear-lanceolate, acute, bordered with ſhallow glandular ſerratures, deſtitute of ſtipulas. *Flowers* on ſimple, axillary, cluſtered ſtalks, reddiſh, but inconſpicuous. *Capſules* more ſtriking, from their enlarged leafy termination. The whole plant, when bruiſed, ſmells ſtrongly of rue or juniper, like moſt of its natural order. See Diosma and Eriostemon.

EMPNEUMATOSIS, from εμπνεω, *I inflate*, in *Medicine*, a word uſed by ſome writers to ſignify an inflation of the ſtomach; but by others, in a more general ſenſe, for inflations of the womb, or of any other part.

EMPOLI, Jacopo da, in *Biography*, a painter of the Florentine ſchool, who was born at Empoli, as his name deſignates, in 1554; and was firſt inſtructed in his art in the ſchool of Maſo di San Friano. He afterwards applied himſelf to ſtudy the works of Andrea del Sarto, and with very conſiderable ſucceſs, acquiring very much his ſtyle of deſign, and hues and tones of colouring. He copied Del Sarto's works very cloſely, and not only his, but thoſe of other maſters, with ſo much accuracy, as to deceive the judgment of thoſe well verſed in the art. So much talent for this kind of exerciſe in art, is ſeldom accompanied by a power of invention or execution of original works. But Empoli had conſiderable reputation for this alſo, and his compoſitions are ſpoken of as poſſeſſing much ſpirit and ingenuity, and alſo exhibiting conſiderable feeling of beauty and elegance.

Empoli, in *Geography*, a town of Italy, in the duchy of Tuſcany, ſituated on the Arno; 15 miles W. of Florence.

EMPORETICA Charta. See Charta and Paper.

EMPORIA, in *Ancient Geography*, a country of Africa, on the Leſſer Syrtis, in which Leptis ſtood. This territory was under the dominion of the Carthaginians, and was put under contribution by Maſiniſſa. Leptis is ſaid to have paid a talent *per* day to the Carthaginians. No part of the Carthaginian dominions was more fruitful than this. Polybius (l. i.) ſays, that the revenue which aroſe from hence was ſo conſiderable, that all their hopes were almoſt founded on it; and he deduces the origin of its name from its great fertility, and the commerce which diſtinguiſhed it. To this were owing the anxiety and ſtate-jealouſy of the Carthaginians, leſt the Romans ſhould ſail beyond the fair promontory, that lay before Carthage, and become acquainted with a country which might induce them to attempt the conqueſt of it.

EMPORIÆ, Ampourias, a town of Hither Spain, which lay towards the ſouth, and which was, as its name imports, a commercial port. Strabo ſays, that the Maſſilians were eſtabliſhed here: but Pliny and Silius Italicus ſay, that they were the Phocæans; both which reports may agree, as the inhabitants of Marſeilles profeſs to have derived their origin from the Phocæans. According to Livy, this place conſiſted of two towns ſeparated by a wall; that on the ſea-coaſt, encompaſſed by a wall of 400 paces, was inhabited by Greeks, a colony of Maſſilians, who ſprung from the Phocæans; and the other part, which had no communication with the ſea, was ſurrounded by a wall of 3000 paces. This hiſtorian informs us, that Cæſar, after having defeated Pompey's party, eſtabliſhed a body of Romans in this place. The Greeks, who were eſtabliſhed in this place, had previouſly inhabited a ſmall iſland oppoſite to it, from which they paſſed over to the continent. They worſhipped Diana of Epheſus.

EMPORICUS Sinus, a gulf of Africa, in Mauritania. Ptolemy places it in the Adriatic ſea, at 34° 20′ of latitude.

EMPORIUM, a fortreſs of Italy, in Emilia, 5 miles from the Po.—Alſo, a place of Macedonia.—Another of Sicily.—Another of Italy, in Campania.—Another in Celtica. Steph. Byz.

Emporium, in *Phyſiology*, is often uſed for the common ſenſory in the brain. See Brain.

EMPRIMED, among *Sportſmen*, a term applied to a hart, when he forſakes the herd.

EMPRION, from πριω, *to ſaw*, in the *Medical Writings of the Ancients*, a word uſed to denote a peculiar pulſe, in which the artery is felt to be diſtended in one part more than another at every ſtroke, and by that means is made to reſemble any ſerrated body, or the light teeth of a fine ſaw.

EMPROSTHOTONOS, in *Medicine*, from ἔμπροσθεν, *forwards*, and τείνω, *I ſtretch*, is the term applied to that form of tetanus, or general ſpaſm, in which the muſcles which bend the body forwards are moſt ſtrongly affected, ſo that the whole body is rigidly fixed in a bent poſition, the neck and back being bowed forwards, the chin fixed upon the breaſt, &c. The term is uſed in oppoſition to Opisthotonos, in which the body is bent backwards. (See Tetanus.) The emproſthotonos, however, is a very rare occurrence; and ſome writers have altogether denied its exiſtence, except as a partial affection confined to the neck.

EMPTOR Familiæ, *buyer of a family*, in the *Roman Law*, one who purchaſed the inheritance of a perſon, or the privilege of being appointed his heir by will.

This was done by the ceremony of ſcales and weights, before five witneſſes, with the uſe of a peculiar formula of words.

Such buyer differed from the heir, *hæres*, as the teſtator in ſome meaſure alienated the right to the former during his own life-time, whereas the latter had only a right by his death. Briſſon. de Formul. lib. vii. p. 585. Pitiſc. Lex. Ant. tom. i. p. 713. voc. *Emptor*.

Emptor *fiduciarius*, *fiduciary buyer*, one who receives a thing in the way of pledge, till the money he has advanced be repaid. Salmaſ. de Mod. Uſur. cap. 14. Pitiſc. Lex. Ant. tom. i. p. 713. voc. *Emptor*.

EMPTYSIS, in *Surgery*, bleeding from the mouth and fauces.

EMPUS, in *Geography*, a town of France, in the department of the Var, and diſtrict of Draguignan; 5 miles N.W. of Draguignan.

EMPUSA, Εμπουσα, among the *Ancients*, a kind of hobgoblin, or bugbear, under the direction of Hecate, who uſed to ſend it to frighten people who laboured under misfortunes. Hofm. Lex. in voc.

EMPYEMA, in *Surgery*, ſignifies a collection of matter in the cavity of the thorax. The term is derived from εν, *within*, and πυον, *pus*, or *matter*.

The ancients made uſe of the word "empyema" to expreſs every kind of internal ſuppuration. Ætius firſt employed the term to denote the collections of purulent matter, which ſometimes form in the cavity of the pleura, or membrane lining the cheſt; and all the beſt modern ſurgeons invariably attach this meaning alone to the expreſſion.

The operation for empyema means the making of an opening into the thorax, for the purpoſe of giving vent to the matter collected in the cavity of the pleura. The neceſſity for having recourſe to ſuch an operation, however, does not often preſent itſelf. We would not wiſh to be thought to aſſert, that inflammation of the lungs, pleura, mediaſtinum, diaphragm, and even of the liver, does not ſometimes terminate in ſuppuration. Certainly, the latter event is occaſionally produced; but, when it does happen, the matter does not always make its way into the cavity of the cheſt. Very frequently external abſceſſes form, or the pus is either coughed up, or diſcharged with the ſtools.

When the ſurface of the lungs and pleura coſtalis have become adherent together, in the ſituation of the abſceſs, the pus, always diſpoſed by a law of nature to make its way to the ſurface of the body, occaſions ulceration of the intercoſtal muſcles, and collects on the outſide of them. An abſceſs of this kind comes on with a deep-ſeated pain in the part affected; an œdematous ſwelling, which retains the impreſſion of the finger; and a fluctuation, which is at firſt not very diſtinct, but from day to day becomes more and more palpable, and, at length, leads the ſurgeon to make an opening to let out the matter.

If an opening be not made, when the fluctuation becomes perceptible, there is ſome riſk of the matter inſinuating itſelf into the cheſt, in conſequence of the adheſion being in part deſtroyed by ulceration. M. Sabatier affirms, that the caſe may take this courſe, even when the abſceſs has been punctured, and while a free external opening exiſts. This experienced ſurgeon had occaſion to remark ſuch an occurrence in a ſoldier. The patient had a collection of matter in the thorax, which was only indicated by a pain all over the ſide; a difficulty of lying in any other poſition in bed, than on the back; and an undulating noiſe in the cheſt, whenever he altered his poſture. When M. Sabatier made the patient hold his breath, the diſcharge, which was very copious, was not increaſed; the pus did not contain any bubbles of air; there was no emphyſema round the wound; nor any blaſt of air from it in the motions of reſpiration. On opening the body, M. Sabatier found, that the abſceſs had been originally ſituated between the intercoſtal, and the pectoralis minor, and major, muſcles, and that the matter had made its way, by ſeveral ulcerated openings, into the cheſt. The lung, in ſome places, was adherent to the pleura. The quantity of effuſed matter was very conſiderable. See Medecine Opératoire, tom. 2. p. 249.

In the ſame manner, if inflammation ſhould occur in the anterior mediaſtinum and end in ſuppuration, the abſceſs may poſſibly burſt into neither of the cavities of the cheſt; but make its way outward, after having rendered the ſternum carious. The following caſe, illuſtrative of this fact, is taken from Van Swieten's Commentaries on Boerhaave's 895th Aphoriſm.

A young man was attacked with a violent pleuriſy, which ſeemed to terminate in copious expectorations, which began about a fortnight after the commencement of the indiſpoſition, and continued for a long while. The patient became exceedingly reduced, and his fate ſeemed inevitable. In the tenth month of his illneſs, however, a ſmall ſoft ſwelling, about the ſize of a filbert, made its appearance upon the middle of the ſternum, the ſubſtance of which bone appeared to be obviouſly carious round the margin of the tumour. The ſwelling burſt of itſelf, and a diſcharge of matter enſued. Pus continued to be emitted from the opening for eight months. The cavity of the abſceſs was capable of containing a pint of the fluid, which was uſed as a detergent injection. The matter had collected between the pleura and the ribs. The patient recovered of this alarming diſeaſe, and was ſeen by Van Swieten in good health, eight months afterwards. There only remained a ſmall fiſtulous opening, from which an inconſiderable quantity of matter continued to be diſcharged.

The foregoing caſe of abſceſs in the anterior mediaſtinum originated from an internal cauſe. It was the conſequence of a violent pleuriſy, or rather of a ſimilar diſorder, which is attended with nearly the ſame ſymptoms, but has a different ſituation, and has been very accurately deſcribed by Salius Diverſus. The ſame ſort of abſceſs may ariſe, in conſequence of a wound in the forepart of the cheſt. An intereſting caſe of this deſcription is related by Galen. A young man, who had been wounded in the region of the ſternum, ſeemed to have got completely well. An abſceſs then formed in the ſituation where the injury was received; it was opened, and healed. The part, however, ſoon inflamed and ſuppurated again. The place could not now be healed. A conſultation was held, at which Galen attended. As the ſternum was obviouſly carious, and the pulſation of the heart was viſible, every one was afraid of undertaking the cure of the caſe, ſince it was conceived, that it would be neceſſary to open the thorax itſelf. Galen, however, engaged to manage the treatment without making any opening of the kind alluded to, and he expreſſed his opinion, that he ſhould be able to effect a cure. Not finding the bone ſo extenſively diſeaſed, as was apprehended, and the mammary veſſels being ſound, he began to indulge conſiderable hopes of ſucceſs. After the removal of a portion of the bone, he ſaw the heart quite expoſed, by reaſon of the pericardium having been deſtroyed by the previous diſeaſe. The patient, after the operation, experienced a ſpeedy recovery.

M. J. L. Petit met with a caſe of an abſceſs in the mediaſtinum, in conſequence of a gun-ſhot wound, in the ſituation of the ſternum. The injury had been merely dreſſed with ſome digeſtive application; no dilatation, nor any particular examination of the wound had been made. The patient, after being to all appearances quite well, and joining his regiment again, was ſoon taken ill with irregular ſhiverings, and often febrile ſymptoms. M. Petit probed the wound, and found the bone affected. As there was a difficulty of breathing, he ſuſpected an abſceſs either in the diploe, or behind the ſternum, and, conſequently, he propoſed laying the bone bare, and applying a trepan. This operation gave vent to ſome ſanious matter, and, as ſoon as the inner part of the ſternum was perforated, a glaſs full of pus was diſcharged. The patient was relieved, and afterwards recovered.

When, in conſequence of inflammation, an abſceſs forms deeply in the ſubſtance of the lungs, the pus more eaſily makes its way into the air-cells, and tends towards the bronchia, than towards the ſurface of the lungs, and into the cavity of the thorax. In this caſe, the patient ſpits up purulent matter. When the opening, by which the abſceſs has burſt, is large, and the pus eſcapes from it in a conſiderable quantity at a time, the patient is in ſome danger of being ſuffocated. However, if the opening be not immoderately large, and the pus, which is effuſed, be not too copious, a recovery may follow. Abſceſſes in the ſubſtance of the diaphragm, and collections of matter in the liver, may alſo be diſcharged by the pus being coughed up from the trachea, when the parts affected have become connected with the lungs, by adheſions, and the abſceſſes of the liver are ſituated on its concave ſurface. When the collection of matter in the liver occupies any other ſituation, the abſceſs frequently makes its way into the colon, and the pus is diſcharged with the ſtools. Several caſes of this kind are related by authors; Sabatier has recorded two in his Médecine Opératoire; Le Dran mentions his having ſeen others; and Pemberton, in his book on the diſeaſes of the abdominal viſcera, p. 36, relates the occurrence of additional inſtances of a ſimilar nature.

We ſhall now proceed to the conſideration of empyema, ſtrictly ſo called. No ſurgical writer, with whom we are acquainted, has written with more diſcrimination, than Mr. Samuel Sharp, on the ſymptoms produced by collections of matter in the cavity of the cheſt. He remarks, that it has been almoſt univerſally taught, that when a fluid is extravaſated in the thorax, the patient can only lie on the diſeaſed ſide, the weight of the incumbent fluid on the mediaſtinum becoming troubleſome, if he places himſelf on the ſound ſide. For the ſame reaſon, when there is fluid in both cavities of the thorax, the patient finds it moſt eaſy to lie on his back, or to lean forwards, in order that the fluid may neither preſs on the mediaſtinum, nor the diaphragm. But, Mr. Sharp takes notice, that however true this doctrine may prove in moſt inſtances, there are a few (Le Dran's Obſ. 217. vol. i. Marchetti, 65.) in which, notwithſtanding the extravaſation, the patient does not complain of more inconvenience in one poſture, than another, nor even of any great difficulty of breathing.

On this account, obſerves Mr. Sharp, it is ſometimes leſs eaſy to determine, when the operation is requiſite, than if we had ſo exact a criterion, as we are generally ſuppoſed to have. However, he informs us, that though this may be wanting, there are ſome other circumſtances, which will generally guide us with a reaſonable certainty. He ſtates, that the moſt infallible ſymptom of a large quantity of fluid in one of the cavities of the thorax, is a preternatural expanſion of that ſide of the cheſt, where it lies; for in proportion as the fluid accumulates, it will neceſſarily elevate the ribs on that ſide, and prevent them from contracting ſo much in expiration as the ribs on the other ſide. Mr. Sharp refers alſo to Le Dran's Obſerv. 211. vol. i. to prove, that the preſſure of the fluid on the lungs may ſometimes be ſo great, as to make them collapſe, and almoſt totally obſtruct their action. When therefore, ſays Mr. Sharp, the thorax becomes thus expanded after a previous pulmonary diſorder, and the caſe is attended with the ſymptoms of a ſuppuration, it is probably owing to a collection of matter. The patient, he obſerves, will alſo labour under a continual low fever, and a particular anxiety from the load of fluid.

Mr. Sharp alſo obſerves, that, beſides this dilatation of the cavity from an accumulation of the fluid, the patient will be ſenſible of an undulation; and ſometimes the undulation is ſo evident, that a by-ſtander can plainly hear it in certain motions of the body. Mr. Sharp adds, that this was the caſe with a patient of his own, on whom he performed the operation; but the fluid, in the example alluded to, he ſays, was very thin, being a ſerous matter, rather than pus.

According to the ſame author, it will alſo frequently happen, that though the ſkin and intercoſtal muſcles are not inflamed, they will become œdematous in certain parts of the thorax; or if they are not œdematous, they will be a little thickened. Theſe ſymptoms, joined with the enlargement of the thorax, and the preceding affection of the pleura or lungs, ſeem unqueſtionably to indicate the propriety of the operation. But, obſerves Mr. Sharp, amongſt other motives to recommend it upon ſuch an emergency, this is one, that if the operator ſhould miſtake the caſe, an inciſion of the intercoſtal muſcles would neither be very painful, nor dangerous. See Critical Enquiry into the preſent State of Surgery; ſect. on Empyema.

Although we would wiſh the reader to underſtand, that patients with empyema can ſometimes lie in any poſition, without any particular aggravation of the difficulty of breathing, yet, we muſt diſtinctly ſtate, that the generality of patients with this diſeaſe cannot place themſelves on the ſide oppoſite to that where the collection of pus is ſituated, without having their reſpiration very materially obſtructed. Another circumſtance, alſo, which we wiſh to mention, now that we are treating of the ſymptoms of empyema, is, that the œdema of the integuments is ſometimes not confined to the thorax, but extends to more remote parts, on the ſame ſide of the body as the collection of matter. Both the foregoing remarks are confirmed by an intereſting caſe, which Mr. Hey, of Leeds, has lately publiſhed.

Sept. 3, 1788, Mr. Hey was deſired to viſit John Wilkinſon, who had been ill ten days of the influenza. The patient was found labouring under a fever, attended with cough, difficulty of breathing, and pain in the left ſide of the thorax. He was bled once; had repeated bliſters applied to the thorax; took nitre and antimonials, with a ſmooth linctus to allay his cough. He was repeatedly relieved by theſe means, eſpecially by the application of the bliſters; but repeatedly relapſed. At laſt, he became ſo ill, that he breathed with the utmoſt difficulty, and "could not lie on the right ſide without danger of immediate ſuffocation."

Mr. Hey found the patient in the ſtate juſt now deſcribed on the 17th of September. "His face, and eſpecially the eye-lid, were a little ſwollen on the left ſide." The left ſide of the thorax was larger than the right, and its integuments were œdematous. Upon preſſing the intercoſtal muſcles they felt diſtended; they yielded a little to a ſtrong preſſure, and rebounded again. The abdomen, eſpecially at its upper part, appeared to be fuller than in its natural ſtate. See Practical Obſervations in Surgery, p. 476.

Another remarkable ſymptom, which is occaſionally produced by collections of matter in the cheſt, is an alteration in the poſition of the heart. Mr. Samuel Cooper has made mention of a patient who was in St. Bartholomew's hoſpital, whoſe heart was puſhed quite to the right ſide of the cheſt, by an empyema in the left bag of the pleura, and pulſated on the right of the ſternum. Firſt Lines of the Practice of Surgery; part 2. chap. 29.

The ſymptoms of empyema are frequently very equivocal, and the exiſtence of the diſeaſe is generally ſomewhat doubtful. Panarolius opened a man, whoſe left lung was deſtroyed, at the ſame time that the thorax contained a conſiderable quantity of pus. Although the patient had been ill for two months, he had ſuffered no difficulty of breathing, and had had only a ſlight cough. Le Dran met with a caſe of nearly the ſame kind. A patient who had been for three days affected with a conſiderable oppreſſion, and an acute pain on the left ſide of the cheſt, got ſomewhat better. He felt no material difficulty of breathing, on whatever ſide he lay. The only thing which he complained of, was a ſenſe of a fluctuation in his thorax, and a little obſtruction to his reſpiration, when he was in a ſitting poſture. Theſe ſymptoms did not ſeem ſufficiently decided to juſtify the operation, and it was delayed. The febrile ſymptoms continued with cold ſweats, and the patient died on the eighth day. Five pints of pus were found collected in the cheſt.

With reſpect to opening ſuch abſceſſes as preſent themſelves at ſome part of the parietes of the thorax, in conſequence of a pleuriſy, or an inflammation of the diaphragm, or mediaſtinum, it is not attended with any peculiarity. It ſhould be done as ſoon as a fluctuation can be felt, and the aperture ſhould be made of ſufficient ſize to give free vent to the matter. As ſome of theſe abſceſſes communicate with the external ſurface of the lungs, and others with that of the liver; as ſome of them are accompanied with a caries of the ribs, or the cartilages of theſe bones, while others are attended with an alteration of the ſubſtance of the ſternum; the cure muſt frequently be interrupted by unpleaſant ſymptoms, and very often retarded for a long while, eſpecially when there are ſome pieces of bone to exfoliate.

We ſhall next conſider the operation for empyema, in the common ſignification of this term.

Mr. Samuel Sharp adviſes the inciſion to be made between the ſixth and ſeventh ribs, half way from the ſternum towards the ſpine; which, ſays he, though not the moſt depending part of the thorax, when we are erect, yet is ſituated ſufficiently low to give iſſue to the fluid, when we lie down.

This author was certainly miſtaken in his opinion, that the expanſion of the lungs always propelled the pus out of the wound, but the action of ſuch muſcles, as diminiſh the capacity of the thorax, may undoubtedly produce this effect. The reader, on looking over the article EMPHYSEMA, will be perfectly convinced, that the lungs cannot become diſtended with air, and expanded on one ſide, while, on this ſide of the cheſt, there exiſts a free communication between the outward air and the cavity of the pleura.

Mr. Sharp quotes the practice of Marchetti, who always made the opening between the fifth and ſixth ribs, to confirm the prudence of chooſing this ſituation for the inciſion. See Critical Enquiry, &c.

A great many of the moſt eminent writers on the operations of ſurgery have had hardly any other object in view, in the operation for empyema, than making an opening into the thorax in ſuch a ſituation, as would be a moſt depending one, in the erect poſition of the body. Hence theſe authors even ſanction and recommend the unneceſſary plan of cutting through the muſcles of the back to make an iſſue for the matter in the exact place, which, according to their principle, ought to be choſen. We are ſorry, that the reſpectable names of Bertrandi and Sabatier might be adduced in favour of this mode of proceeding.

The ſafeſt, and moſt convenient ſituation, for making an opening into the cheſt, is between the ſixth and ſeventh true ribs, on either ſide, as circumſtances may render neceſſary. The ſurgeon ſhould only recollect, that the two cavities of the pleura are completely diſtinct from each other, and have no communication whatſoever, ſo that, if fluid were contained on the left ſide of the thorax, making an opening into the right cavity would not ſerve for diſcharging the accumulated matter. The practitioner ſhould alſo remember, that, when there is a fluid on both ſides of the cheſt, paracenteſis muſt never be done for the relief of the two collections at the ſame time; becauſe, there is great reaſon to believe, that, as the lungs on one ſide uſually collapſe, when there is a free communication between the air and inſide of the thorax, they would do ſo on both ſides, were an opening made at the ſame time into each bag of the pleura. It is hardly neceſſary to remark, that, in this condition, the patient could not breathe and would die ſuffocated. The operation conſiſts, in making an inciſion, about two inches long, through the integuments, which cover the ſpace between the ſixth and ſeventh true ribs, juſt where the indigitations of the ſerratus major anticus muſcle meet thoſe of the externus obliquus. Here it is unneceſſary to divide any muſcular fibres, except thoſe of the intercoſtal muſcles, and, by putting the patient in a proper poſture, the opening that is made, will be depending enough for any purpoſe whatſoever. The ſurgeon, avoiding the lower edge of the upper rib, where the intercoſtal artery lies, is then cautiouſly to divide the intercoſtal muſcles, till he brings the pleura into view, when this membrane is to be very carefully divided with a lancet. The inſtrument ſhould never be introduced in the leaſt deeply, leſt the lungs ſhould be injured. The ſize of the opening in the pleura ſhould never be larger than neceſſary. The diſcharge of blood and matter will of courſe require a freer aperture, than that of air, or water. If requiſite, a cannula may be introduced into the wound, for the purpoſe of facilitating the evacuation of the fluid, and it may, even in ſome caſes, be proper to let this inſtrument remain in the part, in order to let the water, or pus eſcape, as often as another accumulation takes place. It is obvious, however, that a cannula, for this object, ſhould only be juſt long enough to enter the cavity of the pleura, and ſhould have a broad rim to keep it from ſlipping into the cheſt. A piece of ſticking plaſter would eaſily fix the cannula, which might be ſtopped up with a cork, or any other convenient thing, or left open according as the circumſtances of the caſe, and the judgment of the ſurgeon, may direct.

It is proper to ſtate, that ſome practitioners make the wound between the fifth and ſixth ribs: thus, Mr. Hey, in relating an intereſting caſe of empyema, informs us, that the pain which the patient had felt in his ſide had been moſt acute betwixt the fifth and ſixth ribs, and that there he (Mr. H.) made an opening into the cavity of the thorax. His firſt inciſion was about two inches in length. He cut through the ſerratus and intercoſtal muſcles cloſe to the upper edge of the ſixth rib, and made an opening into the cheſt capable of admitting the tip of his finger. A large quantity of matter was thus diſcharged, and a leaden cannula was introduced into the wound on the ſecond day after the operation, and was retained in its place by a flannel bandage. Mr. Hey did not allow the patient to leave off wearing the cannula, until the diſcharge from the thorax had ceaſed, and he had completely regained his ſtrength. He wore it fifteen months.

Mr. Hey thinks it of great conſequence to retain a cannula in the wound, until all probability of relapſe is removed. This precaution, he apprehends, will not hinder the patient from recovering his ſtrength, even when the uſe of the inſtrument is not abſolutely neceſſary. See Hey's Practical obſervations in Surgery, p. 477, &c.

EMPYEMATA, ſuppurating medicines.

EMPYI, patients with empyema.

EMPYREUM, among *Divines*, denotes the higheſt of the heavens, where the bleſſed enjoy the beatific viſion; called elſo empyrean heaven, and paradiſe.

The word is formed of εν and πυρ, *fire*, becauſe of its ſplendour.

EMPYREUMA, in *Chemiſtry*, is that ſmell and taſte of ſcorching which takes place in moſt animal and vegetable ſubſtances, when heated to that point at which decompoſition by fire begins. It is always attended with a darkening of colour of ſubſtances naturally clear and limpid. The degree of heat at which this change occurs is various, but it is always above that of boiling water, ſo that the uſe of a boiling water-bath for digeſtions, or deſiccations, is an effectual mode of preventing empyreuma. There is, however, a change that takes place in vegetable decoctions or infuſions when evaporated to the conſiſtence of an extract, however low the heat is kept, ſince when theſe extracts are again diluted to their original conſiſtence, they differ both in ſenſible and chemical properties, from the original liquor. The cauſes of this change are, probably, in part the action of the external air, but principally, ſeveral complicated chemical actions that take place between the various component parts of the vegetable ſubſtance itſelf, when their particles are concentrated by evaporation of the water which held them in ſolution. This circumſtance is often confounded with empyreuma, properly ſpeaking, or the changes produced by heat puſhed to the degree at which decompoſition occurs, and as ſome of the effects appear to be nearly ſimilar, it is perhaps impoſſible to adhere ſtrictly to the real diſtinction. The leading circumſtance that indicates empyreuma in vegetable and animal matters is the *charring*, or converſion into black carbon, of part of the ſubſtance thus heated, whence a carbonaceous inſoluble powder is produced, which partly ſubſides on dilution with water, and partly remains finely ſuſpended.

The ſmell and taſte of empyreuma in vegetable infuſions, may be in many caſes got rid of by filtering through recently-burned charcoal powder.

Empyreuma is alſo uſed for the heat remaining upon the declenſion of a fever.

EMPYREUMATIC Acid and Oil, in *Chemiſtry*. When moſt animal and vegetable ſubſtances are diſtilled *per ſe* in a heat gradually urged to redneſs, a dark-coloured ſtrong ſmelling oil almoſt invariably riſes towards the end of the proceſs, which is ſtrongly empyreumatic.

Many vegetable ſubſtances yield alſo, at the ſame time, a ſtrongly acid and empyreumatic liquor, which appears to be chiefly acetous acid generated in the proceſs, and holding much carbonaceous matter in ſolution, from which it may be partly freed by a ſeparate diſtillation in a gentle heat. See Pyroligneous and Pyromucous Acid.

EMRODS, or rather Hæmorrhoids. See Hæmorrhoids.

EMS, in Latin *Amiſia*, or *Amaſius*, in *Geography*, is a conſiderable river of Germany, which has its ſource in the county of La Lippe, in Weſtphalia, flows through Eaſt Frieſland, and falls into the North ſea, near Emden. It gives its name to one of the new departments of Holland, which is the ancient province of Eaſt Frieſland, whoſe chief place is the town of Leuwarden.

Ems, a town of Germany, in the circle of the Upper Rhine, and principality of Heſſe-Darmſtadt; ſeven miles E.S.E. of Coblentz.

EMSBACH, a river of Germany, in the circle of the Lower Rhine, which runs into the Lahne, three miles E. of Limburg, in the electorate of Treves.

EMULATION, is a generous ardour kindled by the brave examples of others, which impels us to imitate, to rival, and, if poſſible, to excel them. This paſſion involves in it eſteem of the perſon whoſe attainments or conduct we emulate, of the qualities and actions in which we emulate him, and a deſire of reſemblance, together with a joy ſpringing from the hope of ſucceſs.

The word comes originally from the Greek αμιλλα, *diſpute, conteſt;* whence the Latin *æmulus*, and thence our emulation.

Dr. Hartley refers emulation to a claſs of the ſympathetic affections, by which we grieve for the happineſs of others; and Dr. Reid, in his "Eſſays," (p. 167,) defines it as a deſire of ſuperiority to our rivals in any purſuit, accompanied with an uneaſineſs at being ſurpaſſed. He claſſes it, together with reſentment, under the head of the malevolent affections, which, though they are parts of our conſtitution, given us by our Maker for good only, and, when properly directed and regulated, of excellent uſe, are nevertheleſs ſubject to exceſs or abuſe, and thus become the ſource and ſpring of all the malevolence that is to be found among men. From the obſervations which he has introduced for the illuſtration of this affection, he infers, that emulation, as far as it is a part of our conſtitution, is highly uſeful and important in ſociety; that in the wiſe and good, it produces the beſt effects without any harm; but in the fooliſh and vicious, it is the parent of a great part of the evils of life, and of the moſt malignant vices that ſtain human nature.

Plato obſerves of emulation, that it is the daughter of envy; if ſo, there is a great difference between the mother and the offspring; the one is a virtue, and the other a vice. Emulation admires great actions, and ſtrives to imitate them; envy refuſes them the praiſes that are their due; emulation is generous, and only thinks of ſurpaſſing a rival; envy is low, and only ſeeks to leſſen him.

Perhaps, therefore, it would be more juſt to ſuppoſe emulation the daughter of admiration: admiration, however, is a principal ingredient in the compoſition of it.

EMULGENT, in *Anatomy*, a term applied to the blood-veſſels of the kidnies. See ARTERIES and VEINS.

EMULSION, from *emulgere*, to milk, in *Chemiſtry* and *Pharmacy*, is any milky opake liquor formed by the diffuſion of any oily or reſinous matter in water, through the medium either of alkalies, or of mucilage, or any other viſcid matter ſoluble in water.

Milk itſelf is a natural emulſion, and when viewed in a powerful microſcope is ſeen viſibly to conſiſt of oily particles ſuſpended in a ſerous liquor. Many vegetable matters form natural emulſions when merely triturated with water, of which kind are almonds, and moſt of the oily nuts, the oil being held ſuſpended by the mucilage or farina with which theſe ſubſtances naturally abound.

All the oils are rendered miſcible with water, when rubbed with mucilage of gum arabic, or with the yolk of egg, or with a ſmall quantity of any alkaline ſalt, and all theſe mixtures are common in pharmacy. Thick ſyrups alſo promote the diffuſion of oily matters in water, but leſs perfectly.

This combination, however, is but temporary, as all the emulſions are decompoſed by mere reſt for ſome hours, and as beſides they are very apt to ferment, they are only uſed in extemporaneous preſcription.

The common emulſion, now called "Lac Amygdalæ," is made by beating an ounce and a half by weight of ſweet almonds, with half an ounce by weight of double refined ſugar, in a marble mortar, and rubbing them well together; adding gradually the quantity of two pints of diſtilled water, and ſtraining the liquid. If two ounces and a half of the mucilage of gum arabic are added to the almonds whilſt they are pounded in the mortar, we ſhall have the arabic emulſion. Theſe emulſions may be uſed as ordinary drink, in caſes which require ſoft cooling liquors. The camphorated emulſion is prepared by grinding half a dram of camphor, and half a dozen ſweet almonds together in a ſtone mortar, and adding by degrees eight ounces of mint water, ſtraining the liquor, and diſſolving in it half an ounce of white ſugar. A table ſpoonful of this emulſion may be taken in fevers, and other diſorders which require the uſe of camphor, every two or three hours.

The emulſion of gum ammoniac is made by grinding two drams of the gum with eight ounces of water poured gradually upon it till it is diſſolved.

This emulſion is uſed for attenuating viſcid phlegms, and promoting expectorations. In obſtinate coughs, two ounces of the ſyrup of poppies may be added to it. It may be adminiſtered in a doſe of two table ſpoonfuls, three or four times a day. The oily emulſion, prepared by mixing ſix ounces of ſoft water with two drams of volatile aromatic ſpirit, and an ounce of Florence oil, and half an ounce of ſimple ſyrup, is ſerviceable in recent coughs: in more obſtinate coughs, it will be better to ſubſtitute for the aromatic ſpirit the paregoric elixir of the Edinburgh Diſpenſatory. A table-ſpoonful of it may be taken every two or three hours.

EMUNCTORY, in *Anatomy*, from *emungo*, to clean or wipe the noſe, is any part of the body, which ſeparates from the blood humours judged to be impure or excrementitious, and therefore hurtful. This proceſs is ſuppoſed to purify the blood. The kidnies and ſkin are called the common emunctories, as they afford very copious ſecretions. This notion of the ſeparation of noxious particles is built on the opinions of the older phyſiologiſts; and conſequently the uſe of the term emunctory has at preſent nearly ceaſed.

EMUNGS, in *Geography*, one of the Pelew iſlands.

ENABY, a town of Sweden, in the province of Eaſt Gothland; 20 miles S. of Linkioping.

ENADA, in *Ancient Geography*, a town of Paleſtine, in the tribe of Iſſachar, according to the book of Joſhua.

ENÆMON, Εναιμων, from αιμα, *blood*, an external medicine which ſtops or ſtanches the blood; or which, by binding, cooling, or drying, cloſes the paſſages of the veſſels before open, or diminiſhes the fluidity and motion of the blood. See STYPTIC.

ENÆOREMA, Εναιωρημα, from αιωνω, *to exalt*, expreſſes ſuch contents of the urine as float about in the middle, reſembling a cloud; and thence alſo called nubecula. See URINE.

ENAGARA, in *Ancient Geography*, an iſland of Aſia Minor, in the Mediterranean ſea, placed by Pliny over-againſt Lycia, and near the iſle of Crete.

ENAIM, a town of Judea, in the tribe of Judah, according to the book of Joſhua.

ENALLAGE, in *Rhetoric*, a figure whereby we change and invert the order of the terms in a diſcourſe, againſt the common rules of language.

The word is derived from the Greek, εναλλαγη, formed of εναλλαττειν, which ſignifies *to change*, as well as the ſimple verb αλλαττειν.

The grammarians too have a kind of enallage, whereby one part of ſpeech, or one accident of a word, is put for another.

Such is the change of a pronoun, as when a poſſeſſive is put for a relative, *e. gr. ſuus* for *ejus;* or of a verb, as when one mood or tenſe is put for another.

ENALURON, in *Heraldry*, is uſed by Guillim to expreſs a bordure charged with birds; as an enaluron of martlets,

martlets, &c. but Mackenzie charges this as a miſtake ariſing from ignorance of the French tongue; enaluron properly ſignifying orle, or in manner of a bordure, and being applicable to a bearing of any thing in that form.

ENAMBUSH, in *Military Affairs*, relates to a device uſed for the purpoſe of ſurpriſing an enemy, either on his route, or when purſuing a ſmall body of troops ſent out for the purpoſe of decoying him into the ſnare. This inſidious practice is often of conſiderable ſervice in the minor branches of warfare, but can rarely be practiſed on a great ſcale; though hiſtory furniſhes us with inſtances of armies having been taken by ſurpriſe, owing to the cunning of their adverſaries, in lying concealed in ſuch places as enabled them to take advantage of an unſuſpecting commander. This, however, is not what in ſtrictneſs is termed an *ambuſh*. That term more properly is confined to that kind of preconcertion, which rather leads an enemy into the danger, by ſome ſuppoſed advantage held out to his acceptance, whether it be for forage, the ſeizing of a depot, the interception of a convoy, or the attack upon ſome weak poſt. Here we ſee an immenſe field open for contrivance and ſpeculation. It is to be underſtood, that when a body of troops is placed in ambuſh, certain intelligence has been obtained of the numbers, route, and object of thoſe who are to be intercepted. If theſe be not previouſly aſcertained, the ambuſcade may prove fatal: ſince, ſhould it turn out that, inſtead of five hundred, five thouſand were to be attacked; that, in lieu of their being foragers laden with booty, they ſhould prove to be a body of light horſe, with riflemen at their backs; or that, inſtead of being a detachment ſent to ſurpriſe ſome ſmall outpoſt, they ſhould be the advanced guard of a ſtrong column:—in either of theſe caſes, a ſad reverſe would take place; for, although at the firſt bruſh, there might be ſome ſurpriſe, and poſſibly ſome confuſion, it would in all probability be but for the moment; after which the aſſailed party would preſs forward with great eagerneſs, and by means of their flanking parties cover the ſpeculators with diſgrace and ruin. The moſt deadly kind of ambuſcade is that wherein fire-arms are rejected, the whole depending upon pikes and cutlaſſes: in ſuch, ſilence is an important object, even in the very moment of falling upon the enemy. This not only prevents the other parts of the line from being able to aſcertain the exact ſituation of the aſſailants, as may always be done by obſerving the flaſhes from muſketry, &c.; but renders it impoſſible to aſcertain their numbers. Add to this, that when men fire, in the dark eſpecially, at a moving object, they are by no means certain of their aim; nor can they ſo ſpeedily recover themſelves, after their pieces may have been diſcharged. Beſides, it is well known that pikes cauſe infinite conſternation, when coming to cloſe quarters; being much longer than the muſket with the bayonet attached, they are infinitely more deſtructive, when properly uſed in this ſpecies of warfare. In many countries, it is next to impoſſible to enambuſh the enemy; while, in others, almoſt every ſpot affords the means of concealment. The great art is, to avoid all common-place modes of laying *perdue*: ſuch are rarely ſucceſsful, owing to that invariable attention paid towards the examination of every ſuch ſuſpicious ſituation. On the other hand, thoſe parts which are leaſt ſuſpected often prove particularly formidable; but where ſuch are reſorted to, the means of retreat, or at leaſt of defence, ought to be fully eſtabliſhed. Thoſe ambuſcades which are the moſt collected, always carry the greateſt probability of ſucceſs: they are leaſt liable to detection, far more pointed in their attack, and moſt calculated for reſiſtance, when prematurely diſcovered. Cavalry is rarely employed in ambuſhes, though a conſiderable body may, if convenient, be poſted in a proper direction, for the purpoſe of ſupporting the infantry concealed in woods, &c. On ſome occaſions, it is even advantageous that ſuch cavalry ſhould be viſible, but in an oppoſite quarter; ſo as to cauſe the force to be attacked to be concentrated, by calling in their ſcouts and videttes; by which thoſe in ambuſh might elſe be diſcovered. This device likewiſe occaſions the baggage to be ſent upon the other flank, out of the way of the cavalry, and leaving that flank towards them free from incumbrance. When this happens, and that the cavalry make a ſhew of charging, the baggage will commonly fall into the hands of thoſe in ambuſcade. Naval ambuſcades are by no means uncommon: it often happening that a well-concerted decoy lures an enemy into ſuch a ſituation as at leaſt places him under conſiderable diſadvantage, or eventually cauſes him to ſurrender. Thus, diſguiſing veſſels by means of new painting; changing their mode of rigging; appearing to avoid rather than to purſue; ſending out a ſlow ſailing veſſel to paſs between a cruiſer and an iſland, behind which a ſuperior force is concealed, &c. &c. are all *ruſes de guerre* in common uſe. One device, which probably would otherwiſe be often practiſed, is contrary to the laws of honour and the rules of war, namely, making ſignals of diſtreſs, with the view to draw an enemy's veſſel to give aſſiſtance, and then to capture her. To aſſume the appearance of being damaged, either by weather or by action, is all fair; becauſe then the enemy bears down as upon a prey, and not as a protector. However, the practice of enambuſhing, whatever advantages it may ſeem to offer, is ſubject to extreme danger: unleſs guided by the moſt certain knowledge of the force to be ſurpriſed, it becomes almoſt invariably a loſing concern, and has the pernicious tendency of creating great diffidence in the conduct of that commander by whoſe inſtructions it is made. Nor can the ſmalleſt ſucceſs be hoped for, unleſs where the peaſantry are friendly diſpoſed, and the country around thoroughly known.

ENAMEL, in *Anatomy*, the hard ſubſtance which covers the crown of the tooth. It is deſcribed in the account of the teeth, contained in the article CRANIUM.

ENAMEL, in the *Arts*. Enamels are vitrifiable ſubſtances, and may be arranged into three claſſes, *viz.* tranſparent, ſemi-tranſparent, and opaque. The two former are chiefly employed in enamelling on gold and ſilver, for watch-caſes, trinkets, and other ſmall articles of jewellery; the latter is principally uſed on copper, for the making of clock and watch-dial plates, and for other plates which, when properly fluxed, are fit for the purpoſe of enamel-painting.

The baſis of all kinds of enamel is a perfectly tranſparent and fuſible glaſs, which is rendered either ſemi-tranſparent or opaque, by the admixture of metallic oxyds. White enamels are compoſed by melting oxyd of tin with the glaſs, and adding a ſmall quantity of manganeſe, to increaſe the brilliancy of the colour. The addition of oxyd of lead, or antimony, produces a yellow enamel; and Kunckel affirms that a beautiful yellow may be obtained from ſilver. Reds are formed by an intermixture of the oxyds of gold and iron; that compoſed by the former being the moſt beautiful and permanent. Greens, violets, and blues, are procured from the oxyds of copper, cobalt, and iron; and theſe, when intermixed in different proportions, afford a great variety of intermediate colours. Sometimes the oxyds are mixed before they are united to the vitreous baſes. Such are the principal ingredients employed in the production of the various enamels; but the proportions in which they are uſed, as well as the degree and continuance of the heat neceſſary to their perfection, conſtitute the ſecrets of the art. Other ſubſtances than thoſe here mentioned are occaſionally uſed in the compoſition of enamels; and it has been ſaid, that the peculiar quality of the beſt kinds of hard or Venetian enamel is owing to the admixture of a particular ſubſtance found on mount Veſuvius, and known to be thrown up by that volcano.

The work of Neri on glaſs, with the notes of Merret and Kunckel, afford many good precepts for making enamels; yet the exact nature and methods of compoſition of the beſt kinds, both of the hard and ſoft enamels, ſtill remain among the arcana of enamelling. The ſoft white enamel is generally called glaſs, and is manufactured at the glaſs-houſe, near the ſite of the Albion mills, on the Surrey ſide of Blackfriars-bridge; the hard enamels are chiefly made at Venice, and, from the operations of the war, are not at preſent to be procured in London. In conſequence of this, the beſt enamel, which formerly, when ſmuggled into the kingdom, has been ſold as low as from 2*s.* to 2*s.* 6*d.* *per lb.*, and even when the duty has been paid at the Cuſtom-houſe, at from 3*s.* to 4*s.*, has progreſſively advanced to a guinea, and from that to 50*s.*; and it cannot now be obtained at any price.

ENAMEL-*Painting*. See PAINTING *on Enamel*.

ENAMELLING. The art of enamelling is of great antiquity, but of unknown origin. That it was practiſed by the Egyptians is evident, from the remains that have been obſerved on the ornamental envelopes of mummies. From them it probably paſſed to the Greeks, and afterwards to the Romans, who appear to have introduced the art into this country; as various Roman antiquities have been dug up in different parts of Britain, in which enamels have formed portions of the ornaments. That the Britons received the art from their conquerors may be conjectured from the circumſtance of enamelled trinkets having been found in Britiſh barrows. That the Saxons practiſed it is certain, from the jewel found at Athelney in Somerſetſhire, and now preſerved at Oxford; which jewel, as appears by the inſcription, was made by command of the great Alfred. The gold cup, given by king John to the corporation of Lynn in Norfolk, proves that the art was not loſt under the Normans; for the ſides of that cup are embelliſhed with various figures, whoſe garments are partly compoſed of coloured enamels. The tomb of Edward the Confeſſor in Weſtminſter Abbey, conſtructed in the reign of Henry III., was alſo ornamented with enamels, pieces of which ſtill remain. The beautiful crozier of the celebrated William of Wykeham, of the time of Edward III., may be alſo adduced as exhibiting ſome curious ſpecimens of the application of this art: and other examples might be pointed out, of its progreſſive deſcent to our own age.

It would ſeem from the above brief review, that anciently enamels were principally applied to the purpoſes of ornament; but ſince the invention of clocks and watches, their uſefulneſs has been proportionally increaſed. For clock and watch dials there is probably no ſubſtance that could be ſubſtituted, that can equal enamel in permanence and beauty: in ſeveral reſpects, it poſſeſſes advantages even over the rich metals of ſilver and gold. Within the laſt 30 or 40 years, an *imitative enamel* has been uſed, and, through the ſcarcity of real enamel, is now in much demand for clock plates; but it is by no means comparable with its prototype: for, being chiefly compoſed of flake white, ground up with ſpirits of turpentine, and afterwards mixed with copal varniſh, it will neither aſſume an equal brilliancy in colour, nor continue unchanged in different climates; on the contrary, the action of the air occaſions it to become dingy and yellow. In fact, imitative enamelling is nothing more than a branch of the art of *japanning*; which ſee.

The proceſſes of enamelling have never been accurately deſcribed. The jealouſies that exiſt in all arts in which any thing like a ſcientific knowledge is wanting, operate to ſecluſion. The practitioner conceals his information from motives of profit, and the amateur ſeldom acquires an inſight ſufficiently minute to enable him to unfold the modes of operation. Whatever may be the defects of the preſent attempt, it will be found to contain a better account of the practical branches of the art than has before appeared.

Enamels are commonly laid upon a metal ground, yet they have been ſometimes uſed in ſubſtance, for diſhes, flower-pots, ornamental veſſels, figures, vaſes, &c. In theſe caſes, the enamel is run into moulds immediately from the pots in which it has been melted. The metals employed to enamel on are gold, ſilver, and copper. Of the other metals, ſome are too fuſible to endure the action of the fire, and the remainder, as platina, &c. are, to uſe the language of the art, too *ſtrong*, for the enamel: that is, the adheſion between the two ſubſtances is not powerful enough to keep them together, the enamel cracking as it grows cold, and flying off the metal in flakes. It appears, therefore, that a certain, however ſlight, degree of oxydation is neceſſary to make the enamel and the metal unite with ſufficient firmneſs. Gold is unqueſtionably the beſt ſubſtance to enamel on, its richneſs of colour ſhowing a beautiful tinge through the enamel: yet the metal generally uſed, except for watch-caſes, and valuable articles of jewellery, is copper; and that on account of its ſuperior cheapneſs. Both the gold and the copper ſhould be of the finer kinds, the others being too refractory to agree properly with the enamel.

By the cuſtom of the trade, rather than from any principle of utility, enamelling is now divided into two branches, *viz.* dial-plate enamelling, and tranſparent enamelling. The former includes the manufacture of clock and watch plates, with fluxed plates for enamel painting, the latter comprehends the enamelling of watch caſes, broaches, pins, and other bijoux: of late years the making of theſe leſſer articles has gradually grown into great diſuſe in this country.

Dial-Plate Enamelling, conſiſts of the two diviſions of hard-enamelling, and ſoft, or glaſs enamelling; in the firſt branch, the Venetian enamels only are employed, in the laſt, the Engliſh or glaſs enamels. The practice of hard-enamelling requires more ſkill, time, and labour than the others, and is conſequently eſteemed the moſt. In preparing the metals to be enamelled on, whether of gold, ſilver, or copper, the proceſs is ſimilar; one deſcription will therefore ſuffice for the whole:—and firſt of the making of watch dials.

The copper being evenly flatted in long ſlips (which is done at the flatting mills between ſteel rollers) and to a proper thickneſs, pieces are cut off for uſe according to the ſize wanted. They are then annealed in a clear fire, in order to make them ſufficiently pliable to take the required forms which is given to them by means of dies. The dies are ſmall circular plates of braſs evenly turned, varying in thickneſs, perhaps, from the ſixteenth of an inch to an eighth, or more, according to their diameter. Some of them are flat, others are hollowed out for the purpoſe of giving a ſlight curve to the *copper*, as the metal to be enamelled on is technically termed when prepared for uſe: the edges of the dies are turned off in an oblique direction, and in the centre is a ſmall hole, rather larger than that which is wanted in the dial-plate. A complete ſet of dies varies in ſize from about three-fourths of an inch to two inches and a half, the gradations being very ſmall, perhaps not more than the thirty-ſecond part of an inch between each.

The copper being cut with a pair of ſciſſars nearly to the ſize required and properly annealed, is next placed on the die beſt adapted for the purpoſe, and the eye, or centre hole, is made. This is effected by firſt forcing up the copper into the hole of the die with a ſmall round-headed punch; by this means a ſmall concave bulge is formed, the upper ſide of which is then filed through with a ſmooth grained file; it is then again placed on the die, and preſſed gradually open till it nearly fills the hole with an oval burniſher; it is afterwards preſſed tighter into the hole with a round broach, the burr being occaſionally taken off by the file, and care employed to prevent the eye from cracking. The punch, burniſher, and round pin, are all of ſteel; the two latter taper in regular gradation towards the handles.

When the eye is completed, the edge of the copper is cut round, ſo as to leave a ſmall part, probably about the thirtieth of an inch, projecting beyond the die. The projecting part is then turned up, or burniſhed, againſt the edge of the die, the copper being firſt laid ſmooth and flat by the burniſher. The turned-up edge of the copper is afterwards filed evenly round, and reduced to the proper height, according to the thickneſs of the braſs-edge, or rim, to which it is to be fixed when in the watch. The inſide burr is then ſcraped off with a graver, and ſtill further cleared away by means of a ſcratch-bruſh: this latter tool is compoſed of ſmall braſs or ſteel wire tied together in a round bundle, about the ſize of the little finger. The purpoſe for which the eye of the copper is formed, and the edge turned up, is to retain the enamel in its proper place, ſo that the plate may be finiſhed both ſquare and neat.

According to the kind of watch to which the dial is to be applied, the copper, if for a ſeconds watch, muſt be kept almoſt flat; or if for a watch where a greater ſpace is wanting beneath, to give more ſcope for the wheels, muſt be raiſed from the edge to the centre in a regular and exact manner. To effect this a ſmall circular block or ſetting die is uſed, made of box or other hard wood turned out to the neceſſary degree of concavity, and having a hole in the middle to receive the eye of the copper when placed within the hollow of the block. The copper is then gradually ſet up to the convexity or height required by rubbing it gently yet firmly with a bent, or ſetting ſpatula, formed of a thin ſlip of ſteel, about five inches long, properly fixed. It is now ready to have the feet ſoldered on, by which it is to be pinned down to the braſs edge or frame of the watch; and the places for the feet being marked on the back of the copper, through the holes drilled for the purpoſe in the edge or frame, the feet are prepared for ſoldering.

The feet are always of wire of the ſame kind of metal as that to be enamelled on, and the wire is drawn into different thickneſſes, proportioned to the ſize of the intended dial-plate; thus varying perhaps from the tenth to the ſixteenth of an inch. In the more common kinds of enamelling, the feet are generally cut off from ſilvered wire, that is, copper wire plated with ſilver; the ſilver itſelf forming the ſolder when the feet and copper are expoſed to the united action of the lamp and blow-pipe. In the beſt kind of work plain copper wire is uſed, and the feet are faſtened to the copper by means of ſpeltre, or of ſilver ſolder. When ſufficient care is exerciſed, either of theſe modes is equally appropriate, but the feet ſoldered on with ſpeltre take the firmeſt hold; thoſe with the ſilvered wire the ſlighteſt. The feet are evenly filed, either to a flat face, or an angular one, according to the deſcription of copper for which they are wanted; and are cut off the wire into proper lengths by a pair of cutting-pliers or nippers. In order to make the feet remain in their places, and facilitate the ſoldering, the end of each foot, before putting it on the copper (which is done by means of a pair of corn-tongs or tweezers), is dipped into a ſlight waſh of borax and water, through which it adheres with ſufficient force to admit of its being expoſed to the power of the blow-pipe. The lamp in common uſe contains from a pint to a quart of oil, and has a cylindrical ſpout projecting about three inches, and being an inch or more in diameter. This ſpace is filled with cotton, which being lighted, a good ſtrong flame is produced. The copper is carefully placed upon a piece of ſolid charcoal, long enough to be held in the hand, and the flame being then propelled by the blow-pipe againſt the ſolder, or ſilvered wire, as the caſe may be, the feet are firmly united to the copper. In this operation, attention muſt be given to the exact degree of heat required to fuſe the ſolder, for ſhould it be too powerful, the copper itſelf will melt at the ſame inſtant: care muſt be taken alſo that all the feet keep in their due places, otherwiſe the copper will not fit properly, and the feet muſt either be cut off, and new ones ſoldered on, or much trouble will be found in drawing the holes of the braſs-edges or frames, to get the coppers into their proper centrical ſituations.

The copper being thus far advanced is thrown into the pickling-pan, in order to free it from the ſcale or oxydable covering acquired from the heat. The *pickle* is either oil of vitriol, ſufficiently neutralized for the purpoſe by water, or elſe a ſolution of the beſt double aquafortis. When the ſcale is enough ſoftened to admit of its being removed by a ſoft bruſh, uſed with water and a little white ſand, the copper is taken out of the pickle, and all the impurities being waſhed away, it is dried by means of heat, or elſe with a ſoft cloth. In this ſtate, the copper will generally require to be again put into a proper ſhape, by means of the braſs die, and ſetting block, as it is ſcarcely poſſible but that ſome irregularities will be produced through the operations laſt deſcribed. It is alſo hardened in a ſlight degree by rubbing the under ſide with the ſetting ſpatula, and the ſurface with the ſcratch-bruſh. When this is done, the copper is completed, and fit to be enamelled on. It is to be remarked, that when many coppers are prepared at once, much time is ſaved by turning off the edges by means of the lathe and arbour, inſtead of by filing them even in the manner detailed above.

The above are the methods by which the common coppers are prepared; it is now requiſite to deſcribe what are called *French edges*, from their having been firſt made in France. Theſe are of two kinds, the ſolid French edge and the laid-down French edge. To make the former, a piece of copper is taken, either about a ſixteenth or a twelfth of an inch thick, according to the diameter of the intended plate, and a hole being drilled in the centre, the copper is placed upon an arbour, and fixed tightly by means of a ſmall cone and ſcrew-nut fitted to the maundrel. The arbour being then fixed upon a lathe, the edge of the copper is next turned off in an oblique direction, inclining inwards, with a graver, and the copper is then reduced to the proper thickneſs for enamelling from the edge to the centre, by means of a ſcorper and other tools; thus leaving the edge ſolid, and taking care alſo that a ſufficient ſubſtance is left unreduced round the cone, to form the outer circle of the eye. The laid-down French edge is made by preparing a copper in the common way from a thin ſlip, the edge being left rather higher than uſual, and then fixing it upon the arbour, when the edge of the copper being firſt turned perfectly even with a graver, is next forcibly bent inwards by a ſmall triangular tool, (perhaps formed from the end of a three-ſquare file worn ſmooth,) and afterwards ſquared and finiſhed by the graver and ſcratch-bruſh. It is in general neceſſary to reverſe the coppers on the arbour, and turn a ſmall portion of the under ſide away, both of the ſolid and laid-down kinds, in order to make the edge of a due ſharpneſs. The coppers are laſtly ſet up, and the feet ſoldered on, as before deſcribed. French edges are moſtly uſed for watches of a particular kind, where room is wanting, and the dials are fixed upon the frames without a braſs-edge.

When a dial is made for a ſeconds' watch, or for one requiring ſtill more circles than two, the additional eye, or eyes, is made by marking the centres accurately with a point on the under ſide of the copper, and then bulging the copper upwards with a ſmall punch from each centre, by ſtriking it gently with a ſmall hammer into a piece of lead, about three times the thickneſs of a die; the lead forms a ſufficient reſiſtance to prevent the eye from cracking, and is yet ſoft enough to admit of the copper being bulged up evenly. The ſmall eyes are afterwards evened with the file, and opened with a ſmall needle or round-pin to the required ſizes. Some trivial variations in the mode of making the ſeconds' holes, &c. occaſionally occur.

The coppers being thus prepared, the next proceſs is that of *enamelling*, properly ſo called. Where the operations of *hard* enamelling, and *glaſs* enamelling, are diſſimilar, the difference will be deſcribed in proceeding, but to a certain extent they are the ſame.

The enamel, as it comes from the makers, is generally in ſmall cakes from four to five or ſix inches in diameter. In preparing it for uſe, a ſmall hammer is uſed, having one end flat, and the other of the ſhape commonly employed to rivet with. With this the enamel is broken into thin pieces or flakes, by ſtriking the edge of the cake ſmartly as it reſts upon the fore finger of the left-hand. The pieces are then put into an agate mortar, and with a peſtle of the ſame kind are finely pulverized, the ſplinters being prevented from flying about, by keeping the enamel covered with pure water all the time the proceſs of *grinding* is going on. The point at which the trituration ſhould be diſcontinued, can only be aſcertained from experience, as the different kinds of enamel, and the different modes of its application, require the *ground* enamel to be either more or leſs fine. In general it may be ſtated, that the *backing* ſhould be much finer than the *firſt coat;* the *ſecond coat* of an intermediate fineneſs; the hard enamels conſiderably finer than the glaſs, and the flux ſtill finer than thoſe, as the fire operates with leſs effect upon the flux than upon either of the former ſubſtances. In grinding, great care muſt be taken to keep the enamel free from dirt, and the light flue which ariſes muſt be waſhed away three, four, or more times, as may be neceſſary in the courſe of the operation, till the water comes off quite clear. A ſmall tea-pot is commonly uſed to pour the water from, and when the enamel is ground ſufficiently, the produce is emptied into ſome other ſmall cup for uſe, the ſurface being kept juſt covered with water.

The manner in which the grinding is performed, is by placing the mortar upon the work-board, on a coarſe piece of flannel or linen, twice or thrice doubled, and wetted to prevent its ſlipping. The handle of the peſtle is then graſped firmly about the middle with one hand, and the palm of the other being placed upon the top, the operator inclines the upper part of his body over the mortar, and cruſhes the enamel by preſſing forcibly with his breaſt upon that hand which covers the peſtle. This motion is repeated in quick ſucceſſion, till all the larger pieces are reduced into coarſe and uneven grains; which grains are afterwards ground to the requiſite equality and fineneſs, by holding the mortar firmly down with one hand, and with the other giving a circular direction to the peſtle, uſing at the ſame time as much ſtrength as can be conveniently exerted.

In enamelling watch dials, many coppers are uſually prepared to go on with at once; that method poſſeſſing the three-fold advantage of ſaving time, materials, and labour. When the enamel is ground, therefore, the coppers having been firſt cleanſed by the pickle, and carefully bruſhed out with water, are ſpread, face downwards, over a ſoft half-worn cloth, or ſmooth napkin, and a thin layer of hard enamel, called, in its ground ſtate, the *backing*, is ſpread over the under ſides with the end of a quill, properly cut, or with a ſmall bone ſpoon. The coppers are then ſlightly preſſed on by another ſoft cloth or napkin, which, by imbibing ſome portion of the water, renders the enamel ſufficiently dry to be ſmoothly and evenly ſpread with the rounded ſide of a ſteel ſpatula. The water is then again dried out by the napkin, and a yet further evenneſs produced by going over the enamel as before, with the ſpatula, and theſe operations are repeated, till the back becomes completely ſmooth, and the enamel is of an equal thickneſs all over. It muſt be obſerved, that the water ſhould not be *entirely* abſorbed, as in that caſe the enamel would fall off, in powder, before the ſubſequent operations are completed. When the enamel is properly ſpread, the looſe particles are carefully cleared away from the edge and eye of the coppers; from the former by the ſpatula, from the latter by twiſting round it the pointed end of a quill, and the proceſs of *laying the bottoms* is thus finiſhed. Some ſlight variations to the above method are in uſe among different artiſts, but the difference is ſcarcely important enough to require deſcription. In ſome inſtances the enamel is laid on with the ſpatula itſelf, and the coppers, inſtead of being held between the fingers, are placed upon the round pin, by means of the centre holes, till the backs are duly ſpread: in both modes due care muſt be taken that the coppers are not bent out of their proper forms.

The next operation is to lay the *firſt coats;* that is, to ſpread a layer of *glaſs* enamel over the upper ſides of the coppers. In doing this, the ſurface is firſt bruſhed ſlightly over with a ſmall camel-hair bruſh, or a hare's foot, to remove any dirt or extraneous particles of enamel, as the mixture of any hard enamel with the glaſs would infallibly ſpoil the work. The glaſs is then ſpread upon the coppers in a layer, the thickneſs of which is commonly the ſame as the height of the edge and eye. The water is afterwards ſlightly abſorbed with a clean napkin ſmoothly folded, and the enamel ſpread by a thin, flat ſpatula, till all unevenneſs is removed, and the ſurface lies regularly from edge to centre. The edge being then gently tapped twice or thrice at different places with the ſpatula, the water riſes towards the top, and is again dried off by the napkin, when the enamel is once more made ſmooth by the ſpatula, and the water being wholly taken up by the napkin, or as nearly ſo as can be effected, without diſturbing the enamel, the *firſt coats* are placed upon rings for *firing*.

The rings uſed in enamelling are generally made of a mixture of pipe-maker's clay and Stourbridge clay, rolled up into the form of cylinders, and turned in a lathe by means of a cylindrical piece of wood forced through the centre of the maſs when wet. Each ring is about a quarter of an inch in thickneſs, and the ſame in depth; the upper ſide is prepared for uſe by rendering it ſlightly concave, which is done by rubbing it carefully upon a half globe of lead ſprinkled over with fine ſilver ſand: the under ſide is nearly flat. Through the concavity thus given to the rings, the edge of the copper or dial-plate only is ſuffered to touch, by which means the enamel on the back remains undiſturbed, and the edges are prevented from ſticking by rubbing over the ſurfaces of the rings with ſoft chalk or whiting.

The firſt coats having been placed carefully upon the rings, are next put into a ſhallow tin veſſel, called a tin cover, which is either made ſquare or round, according to the fancy of the artificer, and is commonly about three quarters of an inch in depth. All the moiſture is then ſlowly evaporated from the enamel, by placing the cover upon a German ſtove, or in ſome other convenient ſituation near a fire, where the evaporation can be properly regulated: for, ſhould the water be dried off too quickly, the work would be in danger of ſpoiling from *blebs* or *bliſters*. Theſe are very ſmall air-bubbles, which, by riſing to the ſurface of the dial-plates, deſtroy their ſmoothneſs and beauty. They appear to be occaſioned, partly by want of due care in laying on the enamel, and partly by the confinement of the air which the water contained, and which, in the proceſs of firing, becomes rarefied; throwing off, by its expanſion, a portion of the ſurrounding enamel, yet not entirely eſcaping without a very vivid heat, and even then reſolving into black or green ſpecks, ſo coloured through the oxydation of the copper.

The *firing* is executed beneath a muffle, placed in a ſmall furnace ignited with coke and charcoal. (See MUFFLE and FURNACE *Enamellers*.) The furnace being drawn up to a ſufficient heat by means of a regiſter, the firſt coats are taken ſeparately from the tin covers, and placed upon thin planches of clay, or iron, chalked over, and gradually introduced beneath the muffle; where, in a very ſhort time, the enamel melts, or technically *runs;* and becoming properly conſolidated, the firſt coat is complete. Great attention is requiſite in this operation, to prevent the enamel from being over-fired; as in that caſe, the glaſs would loſe ſome portion of its opacity, and other defects alſo be produced, to the detriment of the work. The planches are placed towards the further extremity of the muffle, by means of a pair of ſpring tongs; and as ſoon as the fuſion is ſeen to take place, are turned carefully round, in order that every part ſhould be equally fired. The planches are generally made circular, and ſlightly concave, for the convenience of moving the work without danger of ſhaking off the enamel before it becomes fixed by the heat.

As all ſolids, when reduced to a granulated ſtate, occupy a greater ſpace than before, *et vice verſâ*, it will be found that a very conſiderable depreſſion has been produced in the enamel of the firſt coats by the act of fuſion; and that the edge and eye are now much above the ſurface. This deficiency in ſubſtance it is the office of the *ſecond coats* to ſupply. When the work is cooled, therefore, the ſcale is wholly removed from the edges and eyes by means of a fine-grained Lancaſhire file, or a ſmooth grey-ſtone; and being then waſhed and dried, each plate is put upon a ſmall round wax-block, of ſufficient bulk to be held in the hand, and about four or five inches high. The feet are then either preſſed firmly into the wax which covers one end of the block, or the plate is otherwiſe fixed by means of three ſmall cones of wax placed triangular-wiſe upon the block; care being taken not to ſtrain the enamel by too weighty a preſſure. A ſecond layer of ground enamel is then gently ſpread with a quill, and prepared for firing by the napkin and ſpatula as before; after which the ſecond coats are placed upon the rings, and the moiſture being evaporated in the tin-cover, (one edge of which, both in this and in the preceding operation, ſhould be left a little open to give iſſue to the ſteam,) they are ready for a ſecond fire.

The ſecond firing requires an equally cautious management as the former one. The plates muſt not be over-fired, nor muſt the heat be ſuffered to melt the enamel too rapidly; but a kind of rotatory motion, called *coddling*, muſt be given to the work, by holding the loaded planch lightly with the tongs, and gently drawing the edge of it towards the mouth of the muffle, and then returning it to its former place, till the fuſion be complete; a proper knowledge of which can be gained only from practice. The work is now in a fit ſtate for poliſhing.

Poliſhing, in this art, has a twofold ſignification: it not only means to render bright, according to the common acceptation of the term; but alſo to make even, without any reference to gloſſyneſs. The enamel has a natural brightneſs of ſurface acquired from the fire; and when this is removed, it is only neceſſary again to expoſe it to a due heat, to cauſe it to reaſſume its former character. Yet as this brightneſs exiſts independent of evenneſs, and as evenneſs is eſſential to the perfection of enamelling, it is requiſite, in moſt caſes, to produce that quality by the methods next to be deſcribed.

The materials uſed in poliſhing glaſs plates are grey-ſtones, rag-ſtones, ſometimes called burrs, fine ground ſilver ſand, and water. The grey-ſtones ought to be of a fine grain and even texture, without knots, which would be very detrimental by making deep ſcratches in the enamel, inſtead of wearing it away evenly. The plates are taken ſeparately, and the thin edges are firſt worn off by one of the finer grey-ſtones, till they become ſmooth and equal; after which the eyes are rubbed down, till the centre of each plate is even and ſquare. Either the grey-ſtone or the rag-ſtone is next employed, according to the nature of the work, to wear away all the irregularities that may exiſt on the ſurface of the enamel; the rag-ſtones being only uſed for the more common kinds of dials. This is done in different ways; *viz.* firſt, either by holding the plate upon the fore and middle finger of one hand, and giving it a ſort of circular motion by means of the thumb, whilſt with the other hand the poliſhing-ſtone is rubbed with a forward and backward ſtroke over every part of the ſurface; ſecondly, by holding the poliſhing-ſtone on the work-board with one hand, and with the other rubbing upon it the face of the enamel; or, thirdly, by fixing the plate upon a cork, either by means of the feet, or with a piece of wet flannel, and with the fingers giving it a kind of rotatory motion, whilſt the poliſhing-ſtone is rubbed over it in a ſimilar manner. The ground ſilver ſand is uſed to give ſharpneſs to the poliſhing-ſtones, and wear away the enamel with greater celerity than would be otherwiſe acquired; and the act of poliſhing is continued till all the gloſs is ground off the ſurface. In this operation great care muſt be taken that the preſſure be not too powerful, as the plates will then crack in the fire, and can never, or very rarely, be properly mended.

When the enamel is ſufficiently poliſhed, which is eaſily known by the criterion of all the gloſs being removed, the plates muſt be clean waſhed, and the ſpecks of dirt, &c. picked out with a ſharp graver. They are then well rubbed over with ſome fine ground glaſs, either by means of a cloth, a glaſs mull, or perhaps a ſmall bit of fir-wood cut ſmooth, in order to remove the ſtains that may be left by the poliſhing-ſtones; and the clean water being ſuffered to run over them, they are wiped dry, and again placed upon the rings for firing.

The degree of heat neceſſary for poliſhed plates is determined by the finer or coarſer modes in which they were prepared; as the fuſion is much facilitated by the enamel being free from ſcratches. When the ſurface is properly run, that is, when it becomes perfectly ſmooth, even, and bright, the plate is completed; and when cold, is fit for painting on. See PAINTING *of Clock and Watch Dial-Plates.*

The above deſcription regards more particularly the beſt kinds of work; but for the more common work there are two other modes of enamelling practiſed, which it will be requiſite briefly to explain. The plates made in theſe ways are called *run-down plates*, and *run-down ſecond coats*.

Run-down plates are thoſe which are made by laying the enamel upon the coppers in ſufficient quantity to form plates of the required thickneſs, without putting on a ſecond coat. Both labour and fire are thus ſaved; but that neatneſs, regularity, and ſquareneſs, which are acquired by the firſt method, are rarely obtainable in this: and indeed flat plates can hardly be managed at all in this mode. Run-down plates require more coddling than any other; and a longer continuance of vivid heat is neceſſary to make the glaſs flow to a proper evenneſs of ſurface: the plates being wholly completed with one fire, and without poliſhing. It is obvious that the moſt common work only can be thus manufactured; for that of the next ſuperior deſcription, the run-down *one coats*, are poliſhed off with the rag-ſtone, and undergo a ſecond firing. The run-down ſecond coats are thoſe which are reduced to a ſurface comparatively even by the ſecond fire, and are then painted on without being poliſhed off.

In enamelling *hard-plates* for watches, the coppers and the firſt coats are prepared in the manner above deſcribed; excepting perhaps that the layer of glaſs is rather thinner than in glaſs-work only. The hard enamel, which is generally moſt valued as it approaches to a rich cream colour, is broken down, and ground in the ſame way as the glaſs, if a ſmall quantity alone be wanted; but if otherwiſe, it is firſt broken from the cake with the hammer, and then pounded in a ſteel mortar, till reduced into coarſe grains. Theſe grains are then expoſed to the action of a magnet, in order that all the particles of ſteel that have been broken off the mortar in the act of pounding may be taken away, as they would infallibly ſpoil the work, by riſing in black ſpecks to the ſurface of the enamel, when in the fire. As an additional precaution, alſo, it is neceſſary to put the granulated enamel into a ſmall baſon, and pouring upon it a ſtrong ſolution of oil of vitriol, or aquafortis, to ſuffer it to ſtand for ſome hours, that the ſteel particles, &c. may be wholly diſſolved; after which, the enamel muſt be very carefully waſhed, till the water comes off pure and taſteleſs: for ſhould any of the acid remain, the work would certainly bliſter. The enamel is then ground to the neceſſary fineneſs in an agate mortar, and afterwards ſpread over the firſt coat with a quill, in ſmall quantities, and as evenly as it can be laid, that it may require the uſe of the ſpatula as little as poſſible. The water is then partly abſorbed by a very fine and clean napkin, and the enamel ſmoothly ſpread and cloſely compreſſed with the ſpatula; after which, more water is abſorbed, and the ſpreading is continued till the ſurface lies true and equal. The plate is then put upon a ring, and properly fired; and is afterwards poliſhed by placing it upon a cork, (the top edge being firſt taken off with a fine grey-ſtone,) and wearing away the ſurface, firſt, by a very fine-grained Lancaſhire file, or ſmooth piece of ſteel, and ſilver ſand, ground to an almoſt impalpable powder; ſecondly, by a fine blue-ſtone and ſand; and thirdly, by the blue-ſtone alone. With the latter a ſort of half-poliſh ſhould be given to the enamel; and the nigher that poliſh approaches to complete gloſſyneſs, the better; as the plate will then be finiſhed in the third fire with a leſs degree of heat than would be otherwiſe wanted. In this proceſs, much caution is required to prevent ſcratches, which cannot be *run up* by the fire without giving the enamel a greater heat than it will well bear. When the poliſhing is completed, the plate is carefully cleaned with ground enamel; and ſhould there be any ſpecks, they muſt be picked out with a ſmall and ſharp diamond, and the hollows very dextrouſly filled up with enamel from a quill-point, that they may neither riſe above or ſink below the common ſurface, when the plate is again fired: ſhould they actually do ſo, they muſt be made ſmooth with a blue-ſtone, and the plate muſt undergo a fourth fire, to render the ſurface of one uniform texture and gloſſyneſs. Hard-enamel dials are always conſiderably dearer than glaſs ones, through the greater labour, attention, &c. that are requiſite in making them; and the beſt watches are almoſt always made up with dials of this kind.

In the poliſhing off both of glaſs and hard plates, much addreſs is neceſſary to prevent a ſeparation between the enamel and the edge of the copper; for if too great a preſſure is exerciſed, or if the grey-ſtones, which are employed to wear down the copper, are of too rough a grit, the adheſion will be deſtroyed, and various black indents ariſe round the edge of the enamel, when the plate is again expoſed to the fire. In glaſs dials, theſe defects may be ſometimes amended; but in hard-enamel dials, ſcarcely ever.

The operations of *tranſparent enamelling* are nearly ſimilar to what have been already deſcribed in the making of watch dials. As the work is generally of a more minute kind, greater delicacy of handling perhaps is required; and as the enamels are of various colours and deſcriptions, more cups, veſſels, &c. and additional ſoft cloths or napkins, are wanting to keep them from mixing. Watch caſes are commonly enamelled upon gold, as well as moſt ſuperior articles of the fancy kind; and the ſurface of the gold is frequently engraved into different figures and compartments, before the enamel is laid on; by which means the work aſſumes a beautiful variegated appearance through the vitreous coating.

In enamelling the backs and edges of watch-caſes, &c. quince-water is frequently uſed as the medium by which the enamels are laid on; for this poſſeſſing a more adheſive and retentive quality than common water, better prevents the enamel from flowing from its proper ſituations: for where the convexity is conſiderable, the enamel will of courſe have a tendency to float towards the loweſt part. When enamels of different colours are intended to be employed on the ſame article, which is frequently the caſe in ornamental works, ſmall edges or prominent lines are left in the ſubſtance of the metal, for the purpoſe of keeping the enamels ſeparate; and theſe are poliſhed with the enamel, and reduced with it to a ſimilar equality of ſurface. Tranſparent enamels are not unfrequently poliſhed to complete gloſſyneſs, without expoſing them to an additional fire: in theſe caſes, the work is finiſhed with rotten-ſtone.

It is ſometimes deſirable to take off the enamel from a watch-caſe or trinket, without injuring the metallic part. For this purpoſe it has been recommended to lay a mixture of common ſalt, nitre, and alum in powder, upon the enamel requiring to be removed; and afterwards to put it into the furnace: and when the fuſion has commenced, to throw the caſe, &c. ſuddenly into water, which cauſes the enamel to fly off in flakes.

In ornamental tranſparent work, a very pretty effect is often produced by applying ſmall and very thin pieces of gold or ſilver, cut or ſtamped, into different figures, as acorns, oak-leaves, vine-leaves, bunches of grapes, fruits, &c. upon the ſurface of the firſt coating of enamel, where they are fixed by the fire; and are afterwards covered over by the ſecond layer, through which they appear with conſiderable beauty. When any quantity of fancy-works of ſimilar deſign is wanting, this mode of enamelling is much cheaper to execute than to have the ſurface of the metal itſelf engraved into the required forms.

Clock Dial-Plate Enamelling, is far more laborious than the other branches, and requires conſiderable experience to be properly executed, though the methods of operation are ſoon explained. The copper, being procured from the flatting mills in thin ſlips, and of an adequate diameter and thickneſs, is cut to nearly the required ſize with a pair of ſtrong ſciſſars, a circle having been firſt ſtruck with the compaſſes. If in a ſoft ſtate, it is then cleaned by the pickle, and having been bruſhed out with ſand on a flat board, is waſhed and dried for planiſhing; if otherwiſe it muſt be well annealed before it is thrown into the pickle, where it muſt lie till all the ſcale is enough ſoftened to be removed by the hand-bruſh, ſand, and water.

Planiſhing is a very important part of clock-plate enamelling, and too much care cannot be exerted in the proceſs, as the neceſſary regularity of ſurface almoſt wholly depends upon it. In large plates the action of the fire has a very conſiderable effect, as it cauſes an expanſion in the metal, which, unleſs properly guarded againſt, cannot but operate to the imperfection, and perhaps total ſpoiling of the work. In flatting alſo, a ſort of twiſt is not unfrequently given to the copper, during its paſſage through the rollers, that would aſſuredly cauſe the plate to become uneven and out of ſhape, were it not to be removed by planiſhing and repeated annealings. Another effect produced by the fire, is occaſioning the plate to riſe, perhaps irregularly, towards the centre, and this can only be checked by counteracting the action which the heat would otherwiſe generate in the metal by good planiſhing. To keep a large plate entirely flat is impoſſible; or at leaſt no means have as yet been diſcovered through which that aim can be attained. The beſt way, therefore, to provide againſt the irregularities which the fire might cauſe, is to give to the copper, in the courſe of planiſhing, a ſlight and even riſe or curve from the edge to the centre; this can either be effected by the uſe of large braſs dies, or by a machine adapted for the purpoſe.

The *machine* of which, probably, there is only one in the trade, conſiſts of two principal parts; the one a ſolid maſs of iron, with a concave and poliſhed face, imbedded immoveably in a ſtrong oak block, firmly fixed on a foundation of brick-work, and the top edge hooped with a thick iron ring, to prevent ſplitting; the other, an anſwering and weighty maſs of iron with a convex face, ſimilarly poliſhed, and fixed in an upright frame of timber, but ſo contrived as to become *moveable* by means of ſliding grooves, a rope, a pulley, and a lever, and ſo placed as to fall directly upon the maſs beneath, in a ſimilar way to the monkey of a pile-driving engine. The diameter both of the hammer and the anvil, as the upper and under maſſes of iron may be called, for the ſake of perſpicuity, is about thirteen inches; that ſize being nearly as large as clock dials are ever made or wanted. The convexity of the hammer is exactly fitted to the concavity of the anvil, and may be deſcribed, perhaps, as forming a portion of a circle fifty feet in diameter; and the centres of both are kept true to each other, and conſequently to the regularity of curve, by means of large ſcrews and nuts, which adjuſt the poſition of the hammer by altering the perpendicularity of the bars of iron that the grooves act upon. The power of this machine ſaves much labour in planiſhing, as well as time; yet as it is inſufficient wholly to prepare the coppers, and as the charge of erecting one would be very conſiderable, it will never, perhaps, come into general uſe.

In planiſhing with this machine, it is neceſſary to be provided with various thin circular pieces of lead, evenly flatted, and adapted in ſize to the diameters of the coppers to be planiſhed. Without theſe the ſtroke given by the hammer would have a very imperfect effect; and the impulſe given by the weight of its fall would alſo be continually weakening the foundation and bed of the anvil.

The coppers prepared for planiſhing by this machine are taken ſeparately, (the eyes having been previouſly cut out to a proper ſize by means of an iron punch, an hammer, and a lead block,) and each one is laid upon a lead of a correſpondent diameter, and placed upon the anvil in ſuch a manner that all the centres agree. The hammer, which has been hitherto retained at ſome height by an iron ſtay fixed in one of the timbers, and moving on a pivot, is then let fall, three or four times in quick ſucceſſion, it being each time lifted up to the height of three feet or more, by means of the lever. The hammer is then again faſtened by the ſtay, whilſt the copper is turned over on the lead, after which the operation is repeated, and the copper is then taken off, and another laid down till the whole are gone through. The weight of the hammer, and the impetus acquired by its deſcent, remove moſt of the unevenneſſes in the coppers, yet cannot entirely remedy them: a ſtrong and unequal ſpring will ſtill be felt, and the metal being now rendered hard by the action of the hammer, annealing muſt again be reſorted to, and the coppers muſt be pickled and cleaned as before. The machine is then uſed a ſecond time in a ſimilar way; and afterwards a third, a fourth, a fifth, and even a ſixth and ſeventh time, according to the diameters of the coppers, or to the refractorineſs of the metals, due care being taken properly to anneal and pickle them between every operation.

The coppers will now be found of a regular ſhape, and the ſpring in the metal tolerably uniform; it is eſſential, however, to the perfection of the plate, that the ſpring ſhould be *entirely* uniform from edge to centre, otherwiſe the plate would warp and cockle in the fire. A kind of intermediate proceſs muſt therefore be carried on between the taking the coppers from the machine, and before repeating the annealings. This is performed by means of a circular braſs die, about a quarter of an inch in thickneſs, and from fifteen to eighteen inches in diameter, ſcrewed firmly down to a ſtrong oaken block, having three ſtout legs, placed triangular-wiſe, and of a ſufficient height to uſe conveniently when the artiſt is in a ſtanding poſture. The die ſhould have the ſame degree of curve as the machine, otherwiſe the effect produced by each would occaſion a ſort of reciprocal counteraction. The coppers, having paſſed through the machine, are placed in ſucceſſion upon the die, and a wooden box-hammer (ſomewhat reſembling that uſed by gold-beaters) with two faces, the one a circle about three inches over, the other cut away on the front edges, ſo as to leave only a portion about an inch or an inch and a quarter in breadth remaining in the middle, is then taken, and the copper is both rubbed and ſtruck with it till the metal becomes too hard for any further impreſſion to be made, and requires annealing. The circular end is uſed to ſtrike the copper with, which is done by ſhort, quick beats of the hammer, the artiſt working from centre to edge, and communicating the neceſſary motion and direction to the coppers by means of the fingers of one hand, ſo extended over the work as to give the requiſite command in guiding it: the other end is employed in rubbing the coppers ſtrongly with a backward and forward action, under which they are moved upon the die by the fingers as before. Where the machine is not uſed, the planiſhing muſt then be entirely performed in the way juſt deſcribed, and great care muſt be taken, that in the rubbing, the coppers be not bent, which would occaſion both additional labour, and further annealing. No poſitive direction can be given as to the number of times that the coppers muſt be annealed in the courſe of the planiſhing; as a general rule, it may be ſaid that the larger the ſize, the more frequently muſt the annealings be repeated. For plates of from three to four inches, twice or thrice is commonly enough; from five to eight inches, about four or five times are requiſite; for larger ſizes, the annealings muſt be continued till the ſpring or action in the metal becomes uniform, as already mentioned. This is beſt determined by the regularity with which the copper will flap or jerk into the curve given by planiſhing when turned either ſide uppermoſt upon the die. When the planiſhing is completed, the coppers are cut exactly to the ſizes required, and having been pickled and cleaned, they are then ready to be enamelled on. After the laſt annealing, it is beſt to planiſh but ſlightly, that the coppers may be left in a ſtate of comparative ſoftneſs.

For time-pieces, table clocks, and ſome others, *round* plates are commonly uſed, and in theſe caſes it is neceſſary to have moveable braſs dies formed into the curves required. Round plates are thoſe which have a conſiderable riſe in the centre, made by a pretty quick forcing up of the copper into a ſort of ſhoulder about where the circles of the hours come, and afterwards continuing the riſe more gradually. The bent ſpatula and the ſcratch bruſh are chiefly employed to ſet the coppers into theſe curves, and where the riſe is very quick from the edge, the copper is ſometimes turned up as in ſmall dials, that the enamel may be the better retained in its place.

The quantity of enamel wanting for clock dials renders the grinding it a very laborious and tedious operation; eſpecially as the hard kind only can be uſed with complete certainty. It is true that plates of from ten to twelve inches diameter have been made with glaſs enamel, where particular attention has been given to the *annealing up*, and to the *cooling down*, (phraſes that will be preſently explained,) and where the backing has been of a quality perfectly agreeing with the nature of the glaſs. Of the experiments made in this way, however, the ſucceſs has not always been proportionate to the loſs, and the few enamellers who have clock-furnaces cannot always be induced to repeat them.

The enamel for clock dials is broken down in a ſteel mortar, and afterwards cleanſed and ground in an agate mortar, in a ſimilar way to that prepared for watch plates. Sometimes, where the enamel is of a good quality, the *waſhings* are made uſe of for backing, and no bad conſequence reſults, but this requires conſiderable care in the laying on as well as in properly drying, in order to prevent the ſurface of the back from riſing in bliſters, either entirely or partially. Waſhings is the name given to the almoſt impalpable powder which ariſes in grinding, and floats in the water, intermixed with the duſt and minute hairs which are ſure to fall into the mortar, and which renders it neceſſary that the enamel ſhould be ſeveral times waſhed during the proceſs by pouring off the buoyant matter from time to time, and introducing freſh water, from the tea-pot. Pure ſpring water ought always to be uſed, and a large baſon provided for the reception of the waſhings.

In the beſt and largeſt kinds of work, the waſhings ought never to be uſed, as their great propenſity to bliſter can hardly be counteracted; and when the bliſtering is conſiderable, the plates will aſſuredly *cockle*, or get out of ſhape. The peculiar fineneſs of the waſhings, alſo, occaſions it to be very difficult to lay on as backing in an even manner. Where the enamel in ſubſtance only is uſed, the ſucceſs of the work is rendered more certain; the additional expence therefore is fully balanced by the greater ſecurity.

The general way of putting on the enamel is to lay the copper upon a cloth, twice doubled, and placed upon a die or piece of board, for the conveniency of turning. The backing is then ſpread carefully over it by means of a ſmall ivory or bone ſpoon, and when the whole ſurface is covered, the water is partially dried off by another cloth, and the enamel laid even by a large ſpatula, (ſee SPATULA,) finely poliſhed. Theſe operations are repeated till the back ſurface is ſufficiently evened and dry; when the copper is turned, and the firſt coat laid on and evened in a ſimilar manner. The work is then placed upon a planch for firing, and is next put into the annealing places in the upper part of the furnace, (ſee FURNACE *for Clock-Dials*,) where the humidity is gradually evaporated as the fire draws up. The planches are from a quarter of an inch to three quarters in thickneſs, in proportion to the ſize, and are either made of fine free-ſtone, or of a compoſition of Stourbridge clay, pipe clay, and *old ſtuff*, as the broken muffles, planches, &c. are called, pounded together in an iron mortar, and paſſed through a coarſe ſieve. The face of each planch is either flat or rubbed into a ſimilar curve to that given to the coppers, and before the work is put on to it, a ſlight covering of whiting, dried, is ſifted over it, through a ſmall braſs-wired ſieve: this is done to prevent the enamel from ſticking to the planch when in the act of fuſion.

The muffle is *got up* or rendered hot with ſea-coal, and when ſufficiently vivid, which is known by its near approach to a white heat, the firſt coats are taken from the annealing holes by means of iron prongs, which are ſlid beneath the planches by a ſteady and careful motion, leſt the enamel ſhould be ſhook whilſt in powder; to prevent this, alſo, a farther proviſion is frequently made by means of *irons*, as they are called in the buſineſs, which are placed below the planches, and having a round form, and a convex bottom, are extremely uſeful in moving the work, by admitting the prongs to be readily paſſed below them. The irons are adapted to the ſize of the planches, and are formed out of thin iron plates, and are cut into a circular ſhape; ſome portions of the metal, to render the irons leſs weighty, being wholly removed from between the rim and the centre, which from this circumſtance appear to be connected by croſs bars.

When the firſt coats are properly fired, which can only be determined from practice, they are replaced in the annealing holes, and there left for ſome hours to cool down, all the fire having been firſt raked out from the furnace. The operation of cooling down muſt be effected in a very gradual manner, for were it done too quickly, the plates would crack in different places, through the action of the metal upon the enamel. The particular cauſe of this cracking ſeems to ariſe from the ſurface of the enamel being too ſuddenly fixed by the cold air, to admit of that gradual adjuſtment to the contraction of the metal, which the latter, by retaining the heat longer than the enamel, renders neceſſary. On a ſimilar principle, the annealing up of the ſecond coats muſt be equally progreſſive; for ſhould they be too ſuddenly put into the fire, the metal, by expanding with the heat before the fuſion of the enamel has commenced, would cauſe the enamel to fly through its brittleneſs, and the ſurface would be thereby ſtreaked with cracks.

The enamel for ſecond coats, as in watch plates, muſt be ground finer than for firſt coats, yet not ſo fine as for backing. It is laid on with a ſpoon, and reduced to a ſmooth and equal ſurface by the ſpatula, in the ſame manner as above deſcribed; and the plate being enamelled with the requiſite attention, is fired a ſecond time, and gradually cooled down as before. The next operation is poliſhing.

Clock plates are poliſhed by a ſomewhat different proceſs than watch dials. When perfectly cold they are taken off the planches, and either carefully fixed upon a bed of wet ſand, ſo that not any hollow or vacancy is left below the plate, or imbedded in a ſimilar way with ſand upon wet flannel, twice or thrice doubled. When thus prepared, the ſurface is gradually worn even by means of fine ſilver ſand, paſſed through a ſieve, that the coarſer particles may be prevented from ſcratching the enamel, and poliſhing-ſtones formed of flint pebbles, ground at one end to a regular ſurface. The ſand is uſed with water, and the operation is performed by giving the poliſhing-ſtone a quick circular direction in progreſſive movements over every part of the plate, till the ſurface is evenly reduced, which is known by the gloſſyneſs being wholly worn off: this occupies from half an hour to an hour, or more, according to the ſize and previous evenneſs of the plate. Sometimes the poliſhing is accelerated by uſing pieces of lead or iron, as half-pound weights, for inſtance, in the early ſtage of the proceſs, and afterwards finiſhing with the flint; and that not only to give a ſmooth ſurface to the enamel, but likewiſe to remove the general ſtain or blackneſs which proceeds from the uſe of the lead or iron. When the poliſhing is completed, the plates are well waſhed and bruſhed, and afterwards made perfectly clean by ſome fine enamel being ground over the face of each with a ſmall mull or poliſhing-ſtone for about a quarter or half a minute; the operation being repeated twice or thrice, as may be neceſſary, and the looſe enamel being carefully wiped off with a ſmooth cloth or napkin, after the laſt cleanſing, inſtead of being waſhed away: this is done in order that the ſmall pores which are ſometimes laid open by poliſhing into the ſubſtance of the plate, may be filled up by the minute particles of enamel that eſcape the action of the cloth, but would be removed by the water. Whatever ſpecks or bliſters may be in the plate, are then opened with the diamond, and the holes neatly ſtopped with finely-ground enamel from a quill-point, as in watch-plates; the *ſtoppings up* being ſuffered to lie rather higher than the ſurface, to admit of the reduction in bulk occaſioned by the fuſion. The plates are now again put into the annealing places upon the planches; and the furnace being properly heated, are fired for the third and laſt time, before painting. In this latter firing, great care ſhould be taken that the enamel be not over-fired, which would occaſion a freckled appearance in the plate, when held againſt the light; and if the work is drawn out from the muffle after the fuſion has commenced, and again returned to complete it, the air will be found to have given additional richneſs to the gloſſyneſs of the ſurface. The preciſe time required for firing poliſhed plates can only be known from practice; thoſe on which the fineſt poliſhing-ſand was uſed, and, of courſe, where the ſcratches are leſs deep, wanting leſs heat than when the ſand has been employed in a rougher ſtate. After firing, the finiſhed plates are returned to the annealing-holes, and gradually cooled down for painting on. See Painting *of Clock and Watch Plates.*

In the making of *fluxed plates* for enamel-paintings, ſimilar methods of planiſhing are practiſed to thoſe already detailed; and ſimilar or even increaſed care muſt be taken in deſtroying or regulating the ſpring of the copper. Fluxed plates are commonly either ſquare or oval: in the ſquare ones, about an eighth of an inch, or ſomewhat more, ſhould be cut off each angle of the copper, previous to enamelling, to prevent the danger of breaking them. In preparing them for the flux, every thing is conducted in the ſame way as for clock-dials, till they are poliſhed off, when, inſtead of firing them in their poliſhed ſtate, the flux is laid on as a third coat. In grinding the flux, very particular attention muſt be given to keep it free from dirt; and the grinding muſt be continued till the flux becomes extremely fine, as it will not otherwiſe flow to an even ſurface, when expoſed to the fire, without a more intenſe heat than the ſubſtance will well bear. The flux indeed requires a peculiar delicacy of treatment, and the firing of the fluxed plates muſt be managed with great caution and nicety. The heat which they require in fuſion is much ſtronger than that for enamels only; but the exact point of time for withdrawing them from the furnace muſt be dexterouſly ſeized, leſt the flux ſhould fall into freckles. It is not cuſtomary to poliſh off the flux, as by ſo doing it would be deprived of ſome portion of its brilliant richneſs; yet that perhaps would be in ſome meaſure compenſated for, by the ſuperior evenneſs that would be attained. Fluxed plates muſt be cooled down with great care, as the brittleneſs of the upper coating renders them more liable to crack when too ſuddenly made cool. In fluxing, hard enamel muſt always be uſed; as the flux will not agree with glaſs enamel, but cracks in circles as it grows cold. See Flux.

The greater ductility of gold, and its ſuperior mellowneſs of colour, render it by far the beſt metal that could be employed for the baſis of fluxed plates; though, on account of the expence, it is ſeldom uſed. For naked figures, portraits, or other ſubjects, where much fleſh is exhibited, gold plates ought to be excluſively employed, as their rich hue would ſave conſiderable labour in the painting.

Till the preſent age, fluxed plates were ſeldom made of a larger ſize than four or five inches; but ſince the art of enamel-painting has been carried to ſuch great perfection by Mr. Bone, enamel-painter to the king and the prince of Wales, they have been progreſſively increaſed in extent for his uſe, and are now made of every ſize up to twelve and fourteen inches. The largeſt ever completed meaſures eighteen inches by ſixteen and a half; and Mr. Bone is now employed in painting it from Titian's famous picture of Bacchus and Ariadne, in the collection of lord Kinnaird. See Painting *on Enamel.*

In chuſing enamels for uſe, great experience is neceſſary: indeed the moſt expert practitioner may be deceived, unleſs he make the requiſite trials by aid of the furnace. Some enamels can only be employed alone; others may be uſed for the upper coats, but require a ſtronger kind for the backs; and ſome can be uſed only for backing. Should a new ſort be proffered for uſe, experiment alone is the criterion by which its qualities can be determined. In a ſimilar manner, ſome fluxes will only agree with particular enamels; others muſt be uſed ſeparately; and others again muſt be mixed in grinding, before they can be employed with certainty.

In every branch of enamelling, it is eſſential that the copper, or other metal employed to enamel on, ſhould be of a proper thickneſs. Should the metal be too thick, the plates will always crack, either in their ſecond coats, or in their poliſhed ſtate; and ſhould it be too thin, they would be extremely likely to warp from the too powerful action of the enamel. The due medium can only be aſcertained by practice; for even the different kinds of enamel will require a difference in the thickneſs of the metal.

The proper management of the fire, and the mode by which the muffle is heated, will be explained under the words Furnace and Muffle; it need only be ſtated here, that the time neceſſary to *get up* a clock furnace varies from about an hour and a half to two and three hours, or more, according to the intenſity of the draught, the method of ſtoking, and the quality of the fuel. The work is turned in the muffle by means of ſpring tongs, ſo that each part may have a regular and due heat; and it is returned into the annealing places with the prongs. Should many plates be fired at one time, the labour will be found to be very ſevere, and the heat too powerful; as it carries a flux of blood to the head, and occaſions languor and oppreſſion throughout the whole frame.

Willd. Sp. Pl. v. 2. 231.) Claſs and order, *Hexandria Monogynia*. Nat. Ord. *Sarmentaceæ*, Linn. *Aſparagi*, Juſſ.

Gen. Ch. *Cal.* none. *Cor.* Petals ſix, erect, elliptic-oblong, acute, inferior; three of them exterior; three interior, larger. *Stam.* Filaments ſix, ſhorter than the corolla, equal, awl-ſhaped, dilated at the baſe, ſlightly attached to the bottom of each petal; anthers oblong, verſatile, incumbent. *Piſt.* Germen ſuperior, globoſe; ſtyle the length of the ſtamens, erect, ſwelling, and triangular upwards; ſtigma in three obtuſe lobes. *Peric.* Berry globoſe, of three cells. *Seeds* angular, three or more in each cell.

Eſſ. Ch. Calyx none. Petals ſix, erect; three of them internal. Stigma three-lobed. Berry ſuperior, with three cells and many ſeeds.

1. E. *marginata*. Gærtn. as above. Willd. Sp. Pl. v. 2. 230. Petals nearly equal. Leaves with many ribs.—Our ſpecimens of this pretty little plant were, ſome of them, gathered by Commerſon in the ſtraits of Magellan, and communicated by the celebrated M. de Juſſieu; others by Mr. Archibald Menzies in Staten land near Cape Horn, in Feb. 1787, all of them in bloſſom. Lamarck's figure is a tolerable repreſentation of the whole plant, except the ſtigma, which he erroneouſly draws ſimple and entire. His fruit is copied from Gærtner.—The *roots* are creeping, and throw out cluſters of branched fibres. *Stems* a ſpan high, erect, branched, angular, deſtitute of pubeſcence, as is the whole herb; branches zig-zag, leafy, ſheathed at their baſe. *Leaves* alternate, nearly ſeſſile, upright, about half an inch or more in length, elliptical, acute, entire, ſomewhat revolute, their edges rough with minute ſpines; their underſide marked with three or five ſtrong prominent ribs; the upper even. *Flowers* terminal, ſolitary, drooping, on ſhort ſimple ſtalks. *Petals* white, ribbed; the three outermoſt elliptical; the reſt rather broader and obovate; each of the ſix is ſaid by Gærtner to be marked with two green ſpots below the middle. Commerſon deſcribes three of them only as having a pair of obſolete glands at their baſe. *Berry* the ſize of a pea.

2. E. *buxifolia*. (Phileſia buxifolia; Willd. Sp. Pl. v. 2. 231.) Inner petals thrice as large as the outer. Leaves with numerous tranſverſe veins.—Commerſon alone ſeems to have found this fine ſpecies, in the ſtraits of Magellan. Lamarck's plate, drawn from one of his dried ſpecimens, is a very juſt repreſentation. We have received ſeveral of theſe from Thouin and Juſſieu. The *ſhrub* is two or three feet high, with the aſpect of box, much branched and ſmooth. *Leaves* ſtalked, an inch long, elliptic-oblong, pointed, revolute; green, ſmooth, with a longitudinal furrow above; glaucous, with a central prominent rib, a marginal one at each edge, and numerous tranſverſe veins, beneath: their edges are rough with minute teeth near the point. *Flowers* terminal (not axillary), large and very handſome, apparently reddiſh; their three outer petals elliptical, flat, about half an inch long; the three inner obovate, thrice as long; all veiny. We preſume to unite theſe two plants under one genus, the differences deſcribed in their ſtigmas having no foundation in truth, and there being a ſufficient difference between the outer and inner petals of the firſt, to ſhew that a more ſtriking difference of the ſame kind in the ſecond can only make a ſpecific, not a generic, diſtinction. S.

ENARGIA, Εναργεια, in *Rhetoric*, a figure, which paſſing from the narrative ſtyle, points out, and as it were, ſets the ſubject before the eyes of the audience. Voſſ. Rhet. lib. iii. p. 361.

ENARTHROSIS, in *Anatomy*, is that kind of joint, in which a rounded head of one bone is received into a cup-like hollow of another. See Diarthrosis.

ENBAR, in *Geography*, a town of Aſiatic Turkey, in the Arabian Irak, on the Euphrates; 40 miles weſt of Bagdad.

ENBORNE, a pariſh in the hundred of Kentbury-Eagle, Berkſhire, England, is ſituated 59 miles from London, and contains 46 houſes, and 275 inhabitants. A remarkable and well-known cuſtom is attached to its manors, that if the widow of a copyholder ſhould marry again, or be guilty of incontinency, ſhe forfeits her free-bench, or life-intereſt in her late huſband's copyhold; which is not recoverable but by her ſubmitting to ride into court upon a black ram, repeating ſome ludicrous lines, which end with a petition for her huſband's land. The ſteward of the manor is then obliged to reinſtate her. At every court, the jury ſtill preſent this as one of the ancient cuſtoms of the place. The penalty has not been literally enforced within the memory of man; but it is ſaid, that a pecuniary commutation has been received in lieu of it, which may perhaps have been more readily accepted, from the difficulty of procuring a proper animal for the purpoſe. Lyſon's Magna Britannia, vol. i.

ENCÆNIA, Εγκαινια, a Greek term, ſignifying *reſtauration*, or *renovation*, being compounded of the prepoſition εν, and καινος, *new*.

Encænia is more particularly uſed for the name of a feaſt celebrated by the Jews on the twenty-fifth of the ninth month, in memory of the dedication, or rather purification of the temple, by Judas Maccabæus, after its having been polluted and plundered by Antiochus Epiphanes.

The Jews had alſo two other Encænia, *viz.* the dedication of the temple by Solomon, and that of Zorobabel, after the return from the captivity.

ENCÆNIA is likewiſe applied in the *Fathers*, and *Church-Hiſtory*, to the dedication of Chriſtian churches. See DEDICATION.

Our tranſlators of the Bible do not retain the word Encænia, in St. John, x. 22. where mention is made thereof; in lieu of that, they call it "Feaſt of the Dedication," which is leſs proper. In effect, it is not the feaſt of the dedication, but of the purification or re-conſecration of the temple profaned, that is there ſpoken of.

St. Auguſtine aſſures us, that in his time the uſe of the word Encænia was even transferred to profane matters; and that they called it *Encæniare*, when they put on a new ſuit of clothes.

ENCALYPTA, in *Botany*, from εν, and καλυπτος, *covered* or *veiled*, alluding to the extraordinary ſize of the calyptra or veil, which is a characteriſtic mark of the genus. Extinguiſher-moſs; Schreb. 759. Hedw. Sp. Muſc. 60. Sm. Fl. Brit. 1180. Turn. 17. (Leerſia; Hedw. Fund. v. 2. 88. Bryum; Linn. Gen. 564. Juſſ. 11. Hudſ. 474. Dill. 338.) Claſs and order, *Cryptogamia Muſci*. Nat. Ord. *Muſci*.

Gen. Ch. Male, *Flowers* axillary, compoſed of imbricated ſcales. Female on the ſame plant. *Fl.* terminal, ſeveral abortive. *Capſ.* ſtalked, cylindrical, inclining to ovate, erect, regular. *Fringe* ſimple, of ſixteen linear, upright, thin, paliſh teeth. *Veil* bell-ſhaped, inflated, membranous, much wider than the capſule, erect, often toothed or fringed at the edge.

Eſſ. Ch. Capſule cylindrical. Fringe of ſixteen linear upright teeth. Veil bell-ſhaped, inflated, lax.

This is but a ſmall genus, conſiſting of five ſpecies only in Hedwig's Sp. Muſc. and of four in the Flora Britannica, to which indeed a new one, E. *alpina*, is added in Engl. Bot. t. 1419. The moſt common is E. *vulgaris*. "Veil entire and ſmooth at its margin. Stem nearly ſimple. Leaves lanceolate." Figured in Engl. Bot. t. 558. (*Bryum extinctorium*); and by Dillenius in his t. 45. f. 8. It occurs not unfrequently on ſhady banks, and in the crevices of rocks, and is ſtrikingly diſtinguiſhed by its large and deep veil. E. *ſtreptocarpa*. "Veil contracted and torn at its margin. Stem branched. Leaves oblong. Capſule ſpirally furrowed." Is the largeſt and fineſt ſpecies, long much miſunderſtood by botaniſts. See its figure in Hedw. Sp. Muſc. t. 10. f. 10—15, and Haller's Hiſt. t. 45. f. 3. Dillenius exhibits the leaves and ſtem only, t. 43. f. 71.

Mr. Turner, in his Muſcologiæ Hibernicæ Spicilegium, ſuggeſts an opinion that this genus is not really diſtinct from *Grimmia*, and we confeſs that E. *Davieſii*, Engl. Bot. t. 1281, ſeems not very juſtly referred to it. It is certain that the fringes of ſeveral *Grimmiæ* have the thin pale aſpect ſuppoſed eſſential to *Encalypta*, but their veils are truly thoſe of *Grimmia*.

ENCAMPMENT, in *Military Affairs*, implies the poſition taken for the night, or for any time, of an army, for the purpoſes of exerciſe, or for warfare. It is common in all countries for the regular forces to be called out, at ſtated periods, eſpecially during favourable ſeaſons, from their barracks or quarters, in order to unite for their acting in concert upon a large ſcale, and for their being reviewed by ſome ſuperior officer. Theſe camps are uſually pitched on certain large commons, whereon evolutions may be conveniently performed by ſeveral regiments or brigades, and whoſe ſites are favourable both in regard to ſalubrity, and the eaſy ſupply of water and proviſions. When we ſpeak of encampments in a literal ſenſe, we invariably attach thereto the idea of living under canvas; and ſuch is abſolutely the caſe, when troops are called out for the above purpoſes. But we are not to conclude that in time of war, when on actual ſervice, ſuch takes place on all occaſions: far otherwiſe, for it is a general maxim always to ſpare the camp equipage, as far as may be practicable; and to keep every thing packed, which is not immediately in requiſition: therefore, we uſually ſee regiments, eſpecially of infantry, ſtationed in towns, with lines of pickets in advance, and along their intervals, when the diſtances between ſuch towns may not be great, and the enemy not ſo near at hand as to render ſuch breaks dangerous. Thus, an army of 40,000 men is frequently ſeen to occupy full 20 miles, or even more, in this manner; the different regiments occupying the ſeveral villages along that line, and cloſing up into more compact arrangement, whenever danger may be apprehended. This manner of diſpoſal not only ſaves infinite trouble and delay, reſpecting the camp equipage; but expoſes the army leſs to inclement weather, or to noxious localities; and beſides, facilitates its movements very conſiderably, by allowing the whole to move in ſeparate columns, from one ſtation to another. In this the columns neceſſarily act nearly parallel, much the ſame as in the advance of a battalion by the right or left of companies in open column.

Encampments, by which we mean the mode of laying out the camp into ſtreets and diviſions, are, with ſome trifling variation, formed after the ſame manner in all countries. The general principles are, 1ſt, That no more ground ſhould be occupied than may be abſolutely neceſſary for the drawing up the troops in order of battle: hence, all additions whatever ſhould be made rather in the depth than in the breadth of the camp. This is done to avoid ſuch breaks as could not fail to weaken the line, and to admit the incurſions of the enemy's horſe. It is, however, uſual to allow the interval of about an eighth of their reſpective fronts between battalions of infantry, and of 30 or 40 paces between ſquadrons of cavalry. 2dly, The leaving of paſſages, or ſtreets, throughout, ſo that bodies may move from one part to the other without hindrance, and without being compelled to paſs along the front of the bells of arms. 3dly, That due precaution ſhould be taken for the prevention of diſeaſe, by a judicious arrangement of the regimental and general hoſpitals, as well as by ſecuring the due facility for the removal of filth, and for abundant ventilation; both which can only be effected by due care founded on the precaution of not allowing the camp to be too crowded, either by its ſituation, or the number of perſons contained therein. It is uſual to allow a front of two feet for every file (whether two or three deep) of infantry, and a front of three feet for every file of cavalry: hence camps, wherein the battalions are formed three deep, muſt have their ſtreets full one-half deeper than where the corps are drawn up only two deep. When the ground may permit, the ſtreets are uſually at right angles with the front; each row of tents containing the men of a company, arranged according to their ſeveral ſtations, or numbers, in their companies reſpectively. Suppoſing the whole to be ſtanding at the doors of their reſpective tents, and to be ordered to fall in, they would, by this arrangement, arrive in regular ſucceſſion, either from right to left, or from left to right, at their ſeveral ſtations. The horſes and the tents of a troop of cavalry are arranged in a ſimilar manner. The grenadiers and light infantry are ordinarily encamped in ſingle rows, on the flank; but the battalion companies, in double rows: each two companies thus forming a ſtreet, of which the tent-doors are face to face. This mode certainly looks well, but does not anſwer for all climates. In low latitudes, and in very cold weather, the tent-doors ſhould be pitched from the wind, without regard to appearances. A ſingle row, or one company, occupies nine feet in front; and a double row, or two companies, twenty-one feet; if formed of the old pattern, rectangular tents, which hold only five men each: but if the new bell-tents are uſed, fifteen feet muſt be allowed in front for a ſingle, and thirty feet for a double, row. In the cavalry, a row (or troop) occupies in front as follows:

	Old Tents.		New Tents.
Tent - - - - -	3 yards.	—	5 yards.
From the front pole of the tent to the picket rope -	3 do.	—	3 do.
For the horſe - - - -	6 do.	—	6 do.
For the dung - - - -	2 do.	—	2 do.
Totals - - - -	14 yards.		16 yards.

The breadth of a row in front, whether cavalry or infantry, being multiplied by the number of rows, and the product ſubtracted from the whole extent of the front of a battalion of infantry, or of a ſquadron of cavalry, will leave the ſpace for the ſtreets, which are generally divided thus:

For the infantry,	59½	feet each.
For the cavalry,	30	feet each between the tents.
————	46	feet each between the horſes.

By the foregoing it will be ſeen that the utmoſt order prevails in laying out the tents of the ſoldiery, where the ground will permit. In places abounding with trees, rocks, puddles, &c. it muſt of courſe follow, that the locality of every tent conforms to theſe interruptions: but the main points muſt, nevertheleſs, be ever adverted and conformed to; otherwiſe all thoſe evil conſequences, attendant upon want of management, will inevitably follow. Negligence will admit filth; filth will create diſeaſe; and diſeaſe will produce weakneſs, diſcontent, and deſpair. The following is the diſtribution of the depth of a camp of infantry, or of cavalry, when the ground permits.

Diſtribution of the Depth of a Camp.	Infantry.	Cavalry.
	Yards.	Yards.
From the quarter guard parade to battalion parade - - - - - - -	62	
From this firſt line of parade to the front of the { ſerjeant's tents quarter maſter's tents } - - -	16	
N. B. *Theſe tents open to the front.*		
To the firſt picket of horſes - - - - - - - - - - - -	—	15
Infantry for every tent in depth. ——, old pattern - 9 feet. ——, new pattern - 15 feet. Cavalry, for every horſe - 3 feet.		
N. B. *The infantry privates' tents open to the ſtreet.* *The cavalry ditto to their horſes' heads.*		
Suppoſe infantry 12 tents deep ———- cavalry 60 horſes ditto } old pattern - - - - - - -	36	60
From the laſt tent of infantry, or laſt horſe of cavalry, to the front of the ſubaltern's tent *(openings to the rear)* - - - - - - - - - -	15	12
To the front line of captains *(openings to the front)* - - - - - - -	15	15
To the front of the field officers *(open to the front)* - - - - - - -	10	15
To the colonels - - - - - - - - - - - - -	10	10
To the ſtaff officers - - - - - - - - - - - -	10	14
To the firſt row of batmens' tents - - - - - - - - - -	10	15
To the firſt row of pickets for bat-horſes - - - - - - - - -	2	
To the ſecond row of ditto - - - - - - - - - - -	10	
To the ſecond row of batmen - - - - - - - - - -	2	
To the front of the grand ſutlers' tent - - - - - - - - -	10	
To the centre of the kitchens - - - - - - - - -	15	20
To the front of the petty ſutlers - - - - - - - - - -	15	15
To the rear guard *(opens to the rear)* - - - - - - - - - -	15	15
Total depth required in yards - - - - - - - - -	253	226

The captains and ſubalterns are pitched in the rear of their reſpective companies; the field officers oppoſite the outſide ſtreets of the battalion; the colonels oppoſite the central, or main, ſtreets; the ſtaff officers next to the main ſtreets; the grand ſutlers in the rear of the colonels; and the petty ſuttlers in the rear of the kitchens.

If the ground on which the camp is to be formed will not, owing to a ſwamp in the rear, admit of each troop, or company, being formed in one row perpendicular to the front; the diſtribution of the front of a battalion, or ſquadron, muſt be more contracted than the above; and be laid down as follows. Find how many perpendicular rows will be required, by dividing the number of men in the battalion or ſquadron, by the number the ground will admit of in one row; then the number of rows being multiplied, by the breadth of one in front, will give that part of the front to be occupied by the rows; and the difference between it and the whole front allowed for the battalion, or ſquadron, will be left for the ſtreets; which, if the ſtreets are to be equal, muſt be divided by their number, to find the breadth of each; or is, otherwiſe, eaſily divided into ſtreets of unequal breadths.

When two guns are attached to a battalion, they are poſted on the right in the following order; from the right of the battalion to the centre of the firſt gun, four yards; from this to the ſecond gun, ſix yards. The muzzles of the guns in a line with the ſerjeants' tents. The ſubalterns of artillery, if any, in a line with the ſubalterns of infantry; the rear of the gunners' tents in a line with the rear of the battalion tents.

The park of artillery ſhould always be placed, if practicable, within a ſhort diſtance of water carriage, and have the moſt ready communication with every part of the line. Its form muſt depend on its ſituation. Ten feet are uſually allowed in front for one carriage and its interval, and about fifty yards from the hind wheels of the front row to the fore wheels of the ſecond: this interval ſhould allow ſufficient room for putting the horſes to the carriages, and for a free paſſage along the line. In parks not on immediate ſervice, it is uſual to arrange the guns with their muzzles to the front, but where the guns are likely to be wanted at a ſhort notice, appearances muſt give way to promptneſs, and the gun-carriages muſt be parked with their ſhafts to the front, ready to receive the horſes, or other draught animals.

A quarter-guard is placed in front of the park, and the non-commiſſioned officers' and gunners' tents on the flanks, at about twenty paces diſtant; forty paces to the rear are the ſubaltern officers' tents; at ten more the rear of the captains; and ten more to the front of the commanding officers: the meſs-tent is fifteen paces in rear of the line of officers. At a convenient diſtance, in the rear of the whole, are the horſes, picketted in one or more lines, with the drivers on their flanks. The horſes are ſometimes picketted in lines perpendicular to the front of the park, and on the flanks of the carriages, between the men and the carriages.

An army is ſometimes encamped in two, or even in three, or more lines; according to its numbers, and the nature of the ground. The diſtance between two lines muſt depend entirely on local circumſtances, or on the object in view: ſometimes they are not more than two hundred yards aſunder, and ſometimes full five or ſix hundred; occaſionally they are pitched in reverſe, eſpecially when covering a convoy that has taken poſt between two hills, or rivers, or woods; in ſuch inſtances they are "in reverſe," and, in lieu of rear guards, have a central force to act as a reſerve.

With reſpect to the choice of ground for an encampment, it muſt be recollected that no poſition is tenable, in a military point of view, which does not ſtand exempt from the enfiladeof an enemy. In fact, all commanding grounds ought to be beyond the reach of cannon, ſo that the camp ſhould not be ſubject to moleſtation from ſuch ſituations. Four principal objects demand attention in the choice of a poſition for encampment. 1ſt. The advantages of the ground, as ariſing naturally, in point of defence. 2d. The acceſs to, or the poſſeſſion of, ſupplies for the army. 3d. The particular object to be attained; whether mere ſecurity, the covering of any depot, the cutting off of an enemy's reſources, the communication with other parts, and eſpecially with ſhipping. 4th. The means of retreat if too cloſely preſſed by a ſuperior force.

The front of an encampment, or, as already explained, of a poſition, ſhould be interſected by rivers, ravines, or broken grounds, or any other obſtacles which may prevent the enemy from advancing in order of battle, and oblige him to paſs through defiles: but the front ſhould nevertheleſs be exempt from ſuch obſtacles as might debar the army from moving out of its camp, or advancing when neceſſary. All obſtacles ought to be within reach of the artillery, or the enemy will paſs them unmoleſted. In a flat country, where the ground does not afford commanding ſituations, a poſition is more or leſs eligible according as it may be covered by obſtacles; ſuch as very thick woods, in which there are few roads; large rivulets that cannot be croſſed but by means of bridges; deep and broken ravines; ground much interſected by ditches and hedges; the poſſeſſion of mills, churches, convents, and other buildings that are capable of obſtinate defence, and are within the encampment. A ſituation where the rear is covered by ſwamps has certain advantages, but is attended with this danger, that, in caſe of defeat, retreat muſt be difficult, if at all practicable. The principal obſtacles, if a choice can be made, ought to be thrown upon the flanks, and force the enemy to narrow his front when attacking the encampment; but, if ſuch obſtacles ſhould be of a nature to be eaſily poſſeſſed by him, they will prove peculiarly exceptionable, and ought not to be depended upon, any more than the ſupply of water from ponds, wells, or ſtreams that lie expoſed to his interference. Laſtly, the want of wood, or of water, even though proviſions ſhould be abundant, totally diſqualify a poſition; unleſs, indeed, for a very ſhort occupancy, and rather as a reſting place than an *appui*, or defenſive aid. Theſe deficiencies muſt invariably operate, on large armies eſpecially, ſo as to render ſuch ſituations untenable, whatever advantages they might offer in regard to natural ſtrength, or diſtreſs occaſioned by their occupancy, to the enemy.

ENCANTHIS, a term in *Surgery*, derived from the Greek εν, ſignifying *in*, and κανθος, which implies the *angle of the eye*. By a kind of abuſe of words, which is too common in every language, the Greek writers have applied the name of "encanthis" to a ſmall, roundiſh, unequal, more or leſs conſiderable, ſometimes red, at other times light-coloured tumour, ſituated in the caruncula lachrymalis, which every ſurgeon knows is naturally placed near the angle of the eye.

Profeſſor Scarpa, of Pavia, has ſurpaſſed every author, with whom we are acquainted, in the excellent and intereſting account which he has given of the diſeaſe under conſideration. To him we feel highly indebted for a great deal of the matter, which we are about to inſert. He obſerves, that the incipient encanthis is a ſmall, ſoft, reddiſh, or ſometimes ſlightly livid, excreſcence, which grows from the caruncula lachrymalis, and alſo from the adjacent ſemilunar fold of the tunica conjunctiva. In general, the inveterate encanthis is of very conſiderable ſize, its roots reaching beyond the caruncula lachrymalis and ſemi-lunar fold of the conjunctiva, and extending along the membranous lining of one, or both eye-lids. In conſequence of its being ſituated between the internal commiſſure of the eye-lids, which it hinders from becoming cloſed on the ſide next the noſe, it ſubjects the patient to a great deal of inconvenience, by keeping up a chronic ophthalmy, obſtructing the action of the eye-lids, and, in particular, by rendering the patient incapable of ſhutting his eye. Alſo, partly by compreſſing the orifices of the puncta lachrymalia, and partly by altering their natural direction, the encanthis becomes an impediment to the free paſſage of the tears from the eye into the noſe.

The encanthis, in its early ſtate, has uſually a granulated appearance, like a mulberry; or elſe it is compoſed of little portions reſembling fringe. When the excreſcence has attained a conſiderable ſize, a certain part of it has a granulated appearance, while the remainder looks like a ſmooth, whitiſh, or aſh-coloured ſubſtance, ſtreaked with varicoſe veſſels, and ſometimes extends ſo far over the conjunctiva, covering the ſide of the eye-ball next the noſe, that it reaches to the place where the cornea and ſclerotica meet. When the encanthis has increaſed to this conſiderable pitch, it conſtantly affects, together with the caruncula lachrymalis and ſemi-lunar fold of the conjunctiva, the membranous lining of one, or both eye-lids. In this ſtate, it may be obſerved, that the excreſcence, beſides the roots, which it derives from the caruncula lachrymalis, and conjunctiva, has a firm prominent appendage, or elongation, which extends along the inner ſurface of the upper, or lower eye-lid, in the direction of its edge. In other terms, we may ſtate, that the middle portion, or body (as it were) of the encanthis, near the cornea, divides, in the form of a ſwallow's tail, into two appendages, or elongations, one of which extends along the inſide of the upper eye-lid, covered by the edge of this part, while the other is continued along the inner ſurface of the lower eye-lid, concealed under its margin, and proceeding in the direction from the internal towards the external canthus of the eye.

Scarpa remarks, that the body of the encanthis, or that middle portion of the excreſcence, which reaches from the caruncula lachrymalis and ſemi-lunar fold incluſively, over the conjunctiva of the eye-ball, even to the very edge of the cornea, is ſometimes as prominent as a common nut or a cheſnut. In other inſtances, it is of the ſame ſize, but depreſſed and flattened, as it were, in the middle. However, the body of the excreſcence does not now retain the ſame granulated appearance which it preſented at an earlier period, while one, or both the appendages, extending along the inner ſurface of one, or both eye-lids, ſeem more like a fleſhy, than a granulated ſubſtance.

When the eye-lids are turned out, theſe appendages of the encanthis form a projection forward, and when this is obſervable on both palpebræ, on their being turned out in this manner, the two fleſhy appendages make together a kind of ring, which comes into cloſe contact with the globe of the eye behind. Scarpa informs us, that Fabricius Hildanus was acquainted with this diſeaſe, which he ſucceeded in curing, and which he named *ficus ſcirrhoſus ad majorem oculi canthum*. See Centur. 1. Obſ. 2.

However, Scarpa takes notice, with reſpect to the caſe recorded by Hildanus, that the encanthis had only one appendage, which was ſituated on the inner ſurface, and below the margin, of the upper eye-lid.

Scarpa, in conformity with moſt ſurgical writers, has very accurately explained, that the encanthis, as well as the pterygium, occaſionally puts on a cancerous malignity, which is denoted by the dark-red, or leaden colour of the tumour; by its unuſual degree of hardneſs; by its darting pains, which extend to the forehead, and all over the eye and temples, particularly whenever the excreſcence has been even gently touched; by its tendency to bleed; and, laſtly, by the ulcerations, which occur in ſeveral places, emit a fungous growth, and diſcharge a thin irritating ſanies. Scarpa is of opinion, that this worſt form of the encanthis can only receive palliative treatment, unleſs an attempt at extirpation be made, by removing, together with the diſeaſe, all the parts contained in the orbit, the ſucceſs of which operation he alſo repreſents as exceedingly doubtful.

At the ſame time, that we profeſs the higheſt reſpect for the ſentiments of Scarpa in general, on the ſubject of diſeaſes of the eyes, we cannot ſilently ſubſcribe to his advice, that no endeavour ſhould be made to effect a radical cure of any malignant encanthis, without extirpating all the contents of the orbit. If the diſeaſe were not ſo very extenſive, as to prevent the ſurgeon from making a fair removal of every part of it, without taking away the eye itſelf, what practitioner can doubt, that the latter formidable operation ought to be diſpenſed with. It would be full time enough to have recourſe to this ſevere ſtep, when it had been decidedly evinced, that cutting away the diſeaſed parts alone was inſufficient, and that malignant morbid miſchief ſtill prevailed.

Scarpa informs us, that the benign encanthis, whether of ſmall, or conſiderable ſize, may be cured by exciſion. The ſmall beginning encanthis, whether of a granulated or fringed appearance, and originating from the caruncula lachrymalis and ſemi-lunar fold, or, alſo, from a ſmall portion of the margins of the eye-lids, where they form the internal commiſſure, may be raiſed with a pair of forceps, and be completely cut away cloſely to its baſe with the curved ſciſſars. In order to accompliſh this operation, it is needleſs to follow the plan, which ſome adopt, of introducing a needle and thread through the little excreſcence, with a view of raiſing and detaching it more accurately from the parts, to which it is adherent. This object can be fulfilled with the forceps, without annoying the patient by the punctures, and by drawing a thread through the tumour, for the purpoſe of making a nooſe. However, in taking away ſuch portion of the incipient encanthis, as ariſes from the caruncula lachrymalis, Scarpa very prudently cautions us againſt removing more of the ſubſtance of that body, than the complete eradication of the diſeaſe requires, leſt the loſs of too much ſhould occaſion an irremediable flux of tears from the eye.

When the little excreſcence has been extirpated, the eye ought to be repeatedly waſhed with cold water to get away the blood, and ſhould then be covered with a piece of fine linen and a retentive bandage. About the fifth, ſixth, or ſeventh day, as ſoon as the inflammation, produced by the operation, has quite ſubſided, and ſuppuration from the wound has commenced, Scarpa adviſes us to touch the cut ſurface with a ſmall button of alum, ſcraped into the ſhape of a crayon-pencil, and he alſo recommends a collyrium, containing the zincum vitriolatum and mucilage of quinceſeeds, to be frequently applied to the eye in the courſe of the day. If this plan of treatment ſhould not have the deſired effect of making the wound heal; but, on the contrary, if the cut ſurface of the caruncula lachrymalis and internal angle of the eye ſhould, inſtead of continuing to heal up, put on a fungous appearance, it ſhould be repeatedly touched with the argentum nitratum, care being taken not to apply this cauſtic to the conjunctiva, more particularly, if any part of this membrane ſhould have been wounded. After the deſtruction of the fungous granulations, a collyrium, containing the zincum vitriolatum, will accompliſh the cure, or the practitioner may introduce between the eyeball and internal commiſſure of the eye-lids, three times a day, an ointment compoſed of freſh butter, powdered tutty, and armenian bole. Scarpa alſo acquaints us, that Bidloo ſpeaks much in favour of uſing for the latter purpoſe powdered chalk, either alone, or mixed with calcined alum. See Exercit. Anat. Chir. Decad. 2.

Scarpa informs us, that we may alſo cut away the large inveterate encanthis, either with a flat body, or with one, which projects in the ſhape of a common nut, or cheſnut, and having one, or two fleſhy appendages extending along the lining of one or both the eye-lids. In this inſtance, a ligature cannot be properly made uſe of, becauſe the neck of the tumour is never ſmall enough to allow of being advantageouſly tied. On the contrary, the encanthis, when it is very large, is always extenſively connected with the caruncula lachrymalis, and with the conjunctiva, almoſt as far as where the cornea begins, and it has, moreover, one or two fleſhy appendages, which run along the under ſurface of one or both the eye-lids. For this reaſon, even ſhould the middle part of the encanthis be extirpated with a ligature, ſtill one or both the appendages would ſtand in need of removal, which object could only be accompliſhed by exciſion.

The apprehenſion of the bleeding from the latter operation is quite unfounded, as there are numerous caſes on record, where the operator has cut away a large inveterate encanthis, without any ills ariſing from hemorrhage. Scarpa mentions, that he could relate himſelf ſome caſes which he has met with, in confirmation of the truth of the foregoing ſtatement. This candid writer, however, does not diſſemble, that Pellier records an example, in which a troubleſome degree of bleeding followed the exciſion of an encanthis; but, it is juſtly obſerved, that the particulars of the diſeaſe are undeſcribed, as well as the exact way in which the operation was performed. Had theſe circumſtances been detailed, perhaps they would have explained the reaſon of the unuſual occurrence. Indeed, Pellier himſelf has remarked, "j'ai ſouvent fait cette operation a des excroiſſances de cette nature, et jamais je n' ai èprouvé un pareil accident."

In the caſe of the large inveterate encanthis, referred to above, and in which there was only one appendage continued along the inſide of the upper eye lid, Hildanus, after taking hold of the body of the encanthis with a tentaculum, drawing the tumour towards him, and turning out the upper eye-lid, in order to make the whole of the appendage project forward, detached all this laſt portion from the inſide of the eyelid with a ſmall knife, and afterwards cut away the body of the encanthis from the conjunctiva and caruncula lachrymalis. Scarpa remarks, that as this plan was attended with complete ſucceſs, it ought to be imitated by all practitioners.

However, when the inveterate encanthis, of large ſize, has two appendages, one reaching along the inner ſurface of the upper eye-lid, the other along that of the lower one, Scarpa adviſes the following plan to be adopted. The patient is to be ſeated in a chair, and the upper eye-lid turned out by an aſſiſtant, ſo as to make one of the appendages of the encanthis project forward. This production of the diſeaſe is to be deeply cut into with a ſmall knife, in the direction of the edge of the eye-lid, taken hold of with a pair of forceps, and be completely detached from the inſide of the part, in the longitudinal direction, the diſſection being continued from the external towards the internal angle of the eye, as far as the body of the encanthis. The appendage on the inner ſurface of the lower eye-lid ſhould be ſeparated in the ſame way. Then the middle portion of the encanthis ſhould be lifted up with a pair of forceps, or, (if this cannot be done) with a double hook, and be entirely cut away from the conjunctiva underneath, which covers the eye ball, and from the ſemi-lunar fold, and caruncula lachrymalis. This may be accompliſhed partly by means of a ſmall knife, and partly with the aid of curved ſciſſars. The operator is alſo to cut more or leſs deeply into the caruncula lachrymalis, according as the ſtrength and depth of the roots of the diſeaſe may require; for, it muſt be confeſſed, that, when the encanthis is very large, and of long ſtanding, the ſurgeon cannot always avoid wounding the caruncula lachrymalis ſufficiently to prevent ſome degree of weeping from the eye, after the operation.

The eye ſhould be repeatedly bathed with cold water, and the reſt of the treatment is nearly like that recommended after removing a ſmall incipient encanthis. Scarpa recommends the uſe of collyria of aqua malvæ, and of anodyne and detergent ones, until ſuppuration has fully taken place from the ſurface of the wound. Then mild aſtringents, and the above-mentioned ointment may be uſefully had recourſe to. Scarpa particularly adviſes giving a preference to mild applications, both before and after ſuppuration has taken place, eſpecially when a conſiderable piece of the conjunctiva, covering the white of the eye, has been cut away with the encanthis. See Scarpa Sulle Principali Malattie degli Occhi.

ENCARDION, from καρδια, *heart*, in *Botany*, a name given by the Greeks to what the Latins properly call the mediata in trees, the heart of the wood, or central hard part of it.

ENCATHISMA, from εγκαθημαι, *I ſit in*, in the *Medical Writings of the Ancients*, a term uſed to expreſs a ſort of bath, in which the patient was only to be plunged up to the belly.

ENCAUMA, from εν, and καιω, *to burn*, in *Surgery*, the mark left by a burn; alſo a ſmall abſceſs ariſing from the ſame cauſe. The term is ſometimes applied to a ſuperficial ulceration on the eye

ENCAUSIS, from εν, and καιω, *to burn*, a burn, or the inflammation produced by this ſort of injury; alſo the operation of external heat on the body, as of the ſun, or ſire. In Dr. Cullen's Noſology, the word is ſynonymous with erythema and ambuſtio.

ENCAUSSE, in *Geography*, a ſmall town of France, in the department of the upper Garonne; 12 miles E. of St. Bertrand, remarkable for its ſprings of mineral water.

ENCAUSTIC PAINTING, Εγκαυστικη, from εν, καιω, *inuro*, *I burn in*, is a ſpecies of painting with burnt wax, practiſed by the ancients, and lately revived. Pliny has given the following brief account of the invention and nature of this art: "Ceris pingere ac picturam inurere, quis primus excogitaverit non conſtat; quidam Ariſtidis inventum putant, poſtea conſummatum à Praxitele; ſed aliquanto vetuſtiores encauſticæ picturæ extitere, ut Polygnoti, & Nicanoris, & Arceſilai, Pariorum Lyſippus quoque, Eginæ picturæ ſuæ inſcripſit ἐνέκαυσεν; quod profectò non feciſſet, niſi encauſtica inventa. Pamphilus quoque Appellis præceptor non pinxiſſe tantùm encauſtica, ſed etiam docuiſſe traditur Pauſiam Sycionium, primum in hoc genere nobilem." Lib. xxxv. cap. 11. From this paragraph we learn, that the method of painting in wax, and burning in the picture, was very ancient; nor is it improbable that in former times, when they were unacquainted with dry oils, and tranſparent varniſhes, they ſhould make uſe of this method for preſerving their colours from damps and heats; though ſome imagine, that by *ceris* is meant a compoſition, different from wax, and capable of bearing the fire; and that burning the picture denotes merely enamelling. Pliny in the ſame chapter informs us, that there were anciently two methods of encauſtic painting in uſe: "Encauſto pingendi duo fuiſſe antiquitùs genera conſtat, cerâ & in ebore, ceſtro, *i. e.* viriculo: donec claſſes pingi cæperè. Hoc tertium acceſſit, reſolutis igni ceris, penicillo utendi; quæ pictura in navibus nec ſole, nec ſale, ventiſque corrumpitur." Dr. Parſons maintains, that the *ceſtrum* was a pointed tool uſed in modelling or carving upon ivory or wax; and he ſuppoſes that there is a contraſt between the uſe of the *ceſtrum*, and painting ſhips with a bruſh, and therefore that the term *pingendi* cannot be underſtood to mean the laying on of paint. However, there is a paſſage in Vitruvius, lib. vii. cap. 9. which ſerves to aſcertain the nature of the ancient encauſtic painting. "At ſi quis ſubtilior fuerit, & voluerit expolitionem miniaceam ſuum colorem retinere, &c." *i. e.* if any one is more wary, and would have the poliſhing, or painting, with vermilion hold its colour, when the wall is painted and dry, let him take Carthaginian wax, melted with a little oil, and rub it on the wall with a hair-pencil; and afterwards let him put live coals into a chafing-diſh, and hold it cloſe to the wax; when the wall, by being heated, begins to ſweat, let it be made ſmooth; afterwards let him rub it with wax tapers, and clean linen rags, in the ſame manner as they do the naked marble ſtatues. This the Greeks call *καυσις*. The coat of Carthaginian wax is ſo ſtrong, that it neither ſuffers the moon by night, nor the ſun-beams by day, to deſtroy the colour. From this paſſage we learn the ancient method of painting in wax by inuſtion, more obſcurely expreſſed by Pliny; though Pliny, in another paſſage, expreſsly informs us, that they uſed coloured wax: "Ceræ (he ſays) tinguntur iiſdem his coloribus, quæ inuruntur;" that they employed a pencil to lay on the melted wax; "reſolutis igni ceris, penicillo utendi:" that the picture was fixed by inuſtion, "picturam inurere." And we learn from Vitruvius, that the whole was cleaned and poliſhed with linen rags.

The Punic or Carthaginian wax, the uſe of which is aſcribed to the ancient painters by Varro, Vitruvius, and Pliny, was ſaid to be the beſt, as it exceeded in whiteneſs the Sardinian and Corſican, probably becauſe it was better purified; for the Africans, as we learn from Pliny, were accuſtomed to uſe alkali in order to render this ſubſtance whiter, and alſo to free it, as ſome have ſuppoſed, from all greaſy matter. Wax, however, ſeems to have formed the only ground of wax-painting. The abbé Requeno, who contributed to preſent to the notice of modern painters wax-painting, adds maſtic; but Lorgna converts his wax into ſoap, as Bachelier does with the alkali of Soda. Aſtori adds gum and honey, affirming that thus the wax would be rendered much more yielding and ſofter for the bruſh. Requeno ſeems to aſſign the excluſive poſſeſſion of this art to the Greeks and Romans; but we have reaſon for believing that the knowledge and uſe of encauſtic painting were older than their time, becauſe the Egyptians, who with the Etruſcans were the parents of the greater part of the inventions known among mankind, and from whom the Greeks derived much of their knowledge, were acquainted with and employed encauſtic painting in the ancient ages of their greatneſs and ſplendour. This fact has been deduced from valuable fragments of the bandages and coverings of mummies painted in this manner. A mummy of this kind is mentioned in a treatiſe entitled "Antichita, &c." referred to at the cloſe of this article. No oil-painting, it is ſaid, perhaps only two or three hundred years old, exhibits a white paint that has kept ſo well as that ſeen on the fragment to which we have alluded; and this circumſtance ſufficiently proves the valuable advantage which that method poſſeſſes when compared with the common oil-painting. The wax, inſtead of becoming black by the contact of the atmoſphere, as drying oil does, acquires increaſing whiteneſs, and according to its natural quality, is not decompoſed in the air, and does not ſtrongly attract the oxygen of the calces or metallic aſhes, which are commonly uſed in painting. That beautiful white, which may be obſerved in the Egyptian encauſtic above-mentioned, is, as the author of the treatiſe juſt cited apprehends, nothing elſe but a ſimple earth, and according to his chemical experiments a chalk *(creta,)* which is alſo unalterable. If we conſider this encauſtic fragment, ſays our author, as belonging to the epoch of the firſt violent change, which the religious ſyſtem of the Egyptians experienced, it will be a ſpecimen of painting about 2500 years old; for ſuch is the number of the years that have elapſed ſince Cambyſes overturned the ceremonies and religious worſhip of the Egyptians, not only by the ſword, but by the ſtill more powerful weapons of ridicule. Dead bodies were embalmed there in the time of Herodotus, (ſee EMBALMING); but the cloth in which they were wrapped, or the bandages bound round them, were no longer painted with ſacred characters. The bodies were only incloſed in wooden caſes, which were more or leſs ornamented. If Bochart and Menage be not miſtaken, the name "mummia" is derived from "muim," which ſignifies wax; and one might therefore believe, that the dreſs of embalmed bodies was thus named becauſe wax was employed for painting it; and thence it would follow, that the fragment in queſtion may be claſſed among the oldeſt. Petronius praiſes the freſh appearance which the valuable works of Zeuxis and Apelles had, even in his time; but Cicero, on the other hand, ſpeaks of the paintings of the ancients having ſuffered from blackneſs. The former is ſuppoſed to have ſpoken of wax-painting, and the latter is preſumed to have alluded to paintings in oil. The author, whoſe ſentiments we are now expreſſing, detached 24 grains of the encauſtic painting from the above-mentioned Egyptian fragment; and in his mode of examining it, the mixture of 100th part of a foreign ſubſtance would have been diſcovered with the greateſt certainty: he muſt, he ſays, have perceived the reſin of Requeno, nor could the alkali of Bachelier and Lorgna have eſcaped his notice. But in this Egyptian encauſtic he found nothing except very pure wax, though he varied his analyſis in every known method.

From the words of Vitruvius above cited it appears, that the Romans, who copied the Grecian proceſs, which was borrowed from the Egyptians, mixed the wax with an oil to make it pliable under the bruſh, but no maſtic, alkali, or honey, as ſome have imagined, was employed; what this oil was it is not eaſy to aſcertain. It does not appear that they uſed thoſe fat oils, which are commonly called drying oils, becauſe they could have employed thoſe as we do, without the addition of wax, which would have been altogether ſuperfluous. Fat oils, which do not dry, would not have been proper for that purpoſe, as they would have kept the wax continually in a ſoft ſtate. Our author ſuppoſes, that the Egyptians, in order to uſe wax in their encauſtic painting, muſt have combined it with an ethereal volatile oil, of which no traces ſhould afterwards remain, and that though they might be unacquainted with the art of ſeparating ethereal oils from the many ſubſtances which they contain, they certainly were acquainted with a very volatile thin oil produced by nature, and which in various places iſſues from the earth. This oil was either that called naphtha, which is an exceedingly volatile oil, that entirely flies off and evaporates, without leaving a ſingle trace behind; or the common ſpirit of turpentine, which would very well anſwer the purpoſe. The encauſtum, thus formed, was uſed in the time of the Romans to cover parts, which had been already painted either with water-colours or in freſco; and it was alſo, as we have reaſon to believe, the ſubſtance with which Apelles daubed over his paintings, and which, according to Pliny, made them appear as if covered by a thin plate of talc or tranſparent ſelenite, and gave the colours a wonderful ſoftneſs,

neſs. It might ſtill be employed for preſerving paintings in water-colours, or on plaſter, and ſculptured pieces of marble.

The ancient art of encauſtic painting, after having been long loſt, was reſtored by count Caylus, a member of the Academy of Inſcriptions in France; and the method of painting in wax was announced to the Academy of Painting and Belles Lettres, in the year 1753; though M. Bachelier, the author of a treatiſe "De l'Hiſtoire & du Secret de la Peinture en Cire," had actually painted a picture in wax in 1749; and he was the firſt who communicated to the public the method of performing the operation of inuſtion, which is the principal characteriſtic of the encauſtic painting. The count kept his method a ſecret for ſome time, contenting himſelf with exhibiting a picture at the Louvre in 1754, repreſenting the head of Minerva, painted in the manner of the ancients, which excited the curioſity of the public, and was very much admired. In the interval of ſuſpence, ſeveral attempts were made to recover the ancient method of painting. The firſt ſcheme adopted was that of melting wax and oil of turpentine together, and uſing this compoſition as a vehicle for mixing and laying on the colours. But this method did not explain Pliny's meaning, as the wax is not burnt in this way of managing it. In another attempt, which was much more agreeable to the hiſtorian's deſcription of encauſtic painting, the wax was melted with ſtrong lixivium of ſalt of tartar, and with this the colours were ground. When the picture was finiſhed, it was gradually preſented to the fire, ſo as to melt the wax; which was thus diffuſed through all the particles of the colours, ſo that they were fixed to the ground, and ſecured from the acceſs of air or moiſture. But the method of count Caylus is much more ſimple: the cloth, or wood which he deſigned for the baſis of his picture, is waxed over, by only rubbing it ſimply with a piece of bees' wax; the wood, or cloth, ſtretched on a frame, being held horizontally over, or perpendicularly before a fire, at ſuch a diſtance, that the wax might gradually melt, whilſt it is rubbed on, diffuſe itſelf, penetrate the body, and fill the interſtices of the texture of the cloth, which, when cool, is fit to paint upon; but as water-colours, or thoſe that are mixed up with common water, will not adhere to the wax, the whole picture is to be firſt rubbed over with Spaniſh chalk or white, and then the colours are applied to it; when the picture is dry, it is put near the fire, whereby the wax melts, and abſorbs all the colours.

Mr. J. H. Muntz, in a treatiſe on this ſubject, has propoſed ſeveral improvements in the art of encauſtic painting. When the painting is on cloth, he directs it to be prepared by ſtretching it on a frame, and rubbing one ſide ſeveral times over with a piece of bees'-wax, or virgin's-wax, till it is covered with a coat of wax of conſiderable thickneſs. In fine linen, this is the only operation neceſſary previous to painting; but coarſe cloth muſt be rubbed gently on the unwaxed ſide with a pumice ſtone, to take off all thoſe knots, which would prevent the free and accurate working of the pencil. Then the ſubject is to be painted on the unwaxed ſide with colours prepared, and tempered with water; and when the picture is finiſhed, it muſt be brought near the fire, that the wax may melt and fix the colours. This method, however, can only be applied to cloth or paper, through the ſubſtance of which the wax may paſs; but in wood, ſtone, metals, or plaſter, the former method of count Caylus muſt be obſerved.

Mr. Muntz has alſo diſcovered a method of forming grounds for painting with crayons, and fixing theſe, as well as water colours, employed with the pencil. On the unwaxed ſide of a linen cloth, ſtretched and waxed as before, lay an even and thick coat of the colour proper for the ground: having prepared this colour, by mixing ſome proper pigment with an equal quantity of chalk, and tempering them with water. When the colour is dry, bring the picture to the fire that the wax may melt, paſs through the cloth, and fix the ground. An additional quantity of wax may be applied to the back of the picture, if that which was firſt rubbed on ſhould not be ſufficient for the body of colour; but as this muſt be laid on without heat, the wax ſhould be diſſolved in oil of turpentine, and applied with a bruſh, and the canvas be again expoſed to the fire, that the freſh ſupply of wax may paſs through the cloth, and be abſorbed by the colour; and thus a firm and good body will be formed for working on with the crayons. If cloth and paper are joined together, the cloth muſt be firſt fixed to the ſtraining frame; and then the paper muſt be paſted to it with a compoſition of paſte made with wheaten flour, or ſtarch and water, and about a twelfth part of its weight of common turpentine. The turpentine muſt be added to the paſte when it is almoſt ſufficiently boiled, and the compoſition well ſtirred, and left to ſimmer over the fire for five or ſix minutes; let wax be diſſolved in oil of turpentine to the conſiſtence of a thin paſte; and when the cloth and paper are dry, let them be held near a fire; and with a bruſh lay a coat of the wax and turpentine on both ſides the joined cloth and paper, in ſuch a degree of thickneſs, that both ſurfaces may ſhine throughout without any appearance of dull ſpots. Then expoſe the cloth to the fire or to the ſun; by which means the oil will evaporate, and the wax become ſolid, and be fit to receive any compoſition of colour for a ground, which is to be laid on as above directed in the caſe of cloth without paper.

Almoſt all the colours that are uſed in oil-painting may be alſo applied in the encauſtic method. Mr. Muntz objects, indeed, to brown, light pink, and unburnt *terra di Sienna*; becauſe theſe, on account of their gummy or ſtony texture, will not admit ſuch a coheſion with the wax as will properly fix them; but other colours, which cannot be admitted in oil-painting, as red-lead, red orpiment, cryſtals of verdegris, and red precipitate of mercury, may be uſed here. The crayons uſed in encauſtic painting are the ſame with thoſe uſed in the common way of crayon painting, excepting thoſe that in their compoſitions are too tenacious; and the method of uſing them is the ſame in both caſes.

The encauſtic painting has many peculiar advantages; though the colours have not the natural varniſh or ſhining which they acquire with oil, they have all the ſtrength of paintings in oil, and all the airineſs of water-colours, without partaking of the apparent character or defects of either; they may be looked at in any light and in any ſituation without any falſe glare; the colours are firm, and will bear waſhing; and a picture, after having been ſmoaked, and then expoſed to the dew, becomes as clean as if it had been but juſt painted. It may alſo be re-touched at pleaſure, without any detriment to the colours; for the new colours will unite with the old ones, without ſpots, as is the caſe in common ſize painting; nor is it neceſſary to rub the places to be retouched with oil, as in oil pictures; it is not liable to crack, and eaſily repaired, if it ſhould chance to ſuffer any injury. The duration of this painting is alſo a very material advantage; the colours are not liable to fade and change; no damp can affect them, nor any corroſive ſubſtance injure them; nor can the colour fall off in ſhivers from the canvas. However, notwithſtanding all theſe and other advantages enumerated by the abbé Mazeas, and Mr. Muntz, this art has not yet been much practiſed. Many of theſe properties belong to a much higher ſpecies of encauſtic painting lately diſcovered in England, the colours of which are fixed by a very intenſe heat; nor are the colours, or grounds, on which they are laid, liable to be diſſolved or corroded by any chemical menſtruum, nor, like the glaſſy colours of enamel, to run out of the drawing on the fire. See on this ſubject, Phil. Tranſ. vol. xlix. art. 100. p. 652. art. 101. p. 655. Id. vol. li. art. 8. p. 40. art. 9. p. 53. Muntz's Encauſtic Eloge of Count Caylus, in the Hiſt. de l'Acad. Roy. des Inſcript. & Belles Lettres, vol. xxxiv. Antichita, Vantaggi e Metodo della Pittura Encauſta; Memoria del Ch. Sig. Giov. Fabbroni, &c. Roma, 1797, 4to. Handmaid to the Arts, &c. vol. i. ch. ix. p. 245. 261.

ENCAUSTICE has been ſometimes uſed to denote the art of *enamelling*, which ſee.

ENCAUSTUM Cæruleum, is a name given to powder blue.

Encaustum *ſacrum*, a name given, by many authors, to that fine red colour uſed for illuminating the capital letters in ſome old manuſcripts. Procopius calls it *baphe*, ſome have called it coccus, and ſome cinnabar. It is ſaid that it was made of the purple colour, extracted from the murex, or purple fiſh, with ſome other additions. It is to be obſerved, that however well this colour, when laid on the parchment, or paper, might reſemble the colours of enamel, yet it was as improper to call it encauſtum, which ſignifies a "colour burnt in," as in enamelling it would have been to have called it atramentum, or ink.

ENCEADA da Bela, in *Geography*, a town of Africa, in the kingdom of Adel, on the coaſt of the Indian ſea; 30 miles S. of cape Guardafu.

ENCEINTE, Fr. from *enceindre, to ſurround*, in *Fortification*, the wall or rampart which ſurrounds a place, ſometimes compoſed of baſtions and curtains either faced or lined with brick or ſtone, or only made of earth.

The enceinte is ſometimes only flanked by round or ſquare towers, which is called a Roman wall.

ENCELIA, in *Botany*, Juſſ. 186. Cavanilles Ic. v. 1. 44, t. 61, and v. 3. 6. t. 210, ſee Pallasia.

ENCEPHALI, in *Medicine*, a term employed by ſome writers to ſignify certain worms, ſaid to be generated in the head.

ENCEPHALITES Lapis, in *Natural Hiſtory*, the name given, by authors, to a ſort of coarſe ſtone, ſuppoſed, in ſome degree, to reſemble the human brain. We have, in the foſſile world, many ſtones, named from the parts of animals, which they have, in reality, been formed from, or owed their original to; and theſe are properly enough called by names denoting the things whoſe forms they wear; but it is a very wrong practice, from ſome ſlight external reſemblances, to give ſuch names to things that never can have been ſuppoſed to be ſo entitled to them. No one can be ſo abſurd as to imagine a human brain can be petrified, though a ſtone may accidentally ſomewhat reſemble its form. The perſon poſſeſſed of ſuch an accidental ſpecimen, ſhould have ranked it among the ſtones to which it properly belonged as a ſtone, whether a flint, a pebble, or a nodule, and have named, as an accident only, this form of it; and not have given it a peculiar denomination, as if it were a new ſpecies.

ENCEPHALOCELE, from εγκεφαλος, *the brain*, and κηλη, *a tumour*, in *Surgery*, a hernia of the brain. See Fungus.

ENCEPHALON, from εν, *in*, and κεφαλη, *the head*, in *Anatomy*, ſhould ſignify, according to its etymology, all the parts contained in the head; but it is commonly applied to the brain, as conſiſting of cerebrum, cerebellum, and medulla oblongata, excluſive of the ſurrounding and containing membranes. Hence, Soemmerring's tabula baſeos encephali is a repreſentation of the baſis of the brain. See Brain.

ENCEPPE, in *Heraldry*, denotes chained, or girt round the middle; as is uſual with monkeys, &c.

ENCERIS, in *Pharmacy*, a word uſed by Galen to ſignify ſmall concretions of wax, which formed themſelves in melted plaſters, of which wax was one of the ingredients. As they cooled, the wax cooling firſt, and collecting itſelf into little grumes, ſpoiled the conſiſtence and form of the whole compoſition.

ENCHANTMENT, of *in*, and *canto*, I ſing, denotes certain words and ceremonies uſed by magicians in the practice of their pretended and deluding art; thus called, becauſe the formulæ of their enchantment were generally compoſed in verſe, and deſigned to be ſung. See Charm, Fascination, Magic, Sorcery, and Witchcraft.

ENCHARAXIS from εν, and χαρασσω, *to ſcarify*, in *Surgery*, a ſcarification.

ENCHASING, Inchasing, or Chasing, the art of enriching and beautifying gold, ſilver, and other metal-works, by ſome deſign or figures repreſented thereon, in low relievo. See Sculpture, Relievo, &c.

Chaſing is only practiſed on hollow, thin works; as watch-caſes, cane-heads, tweezer-caſes, or the like. It is performed by punching or driving out the metal to form the figures from within ſide, ſo as to ſtand out prominent from the plane or ſurface of the metal.

In order to this, they have a great number of fine ſteel blocks, or puncheons, of divers ſizes; and the deſign being drawn on the ſurface of the metal, they apply the inſide upon the heads or tips of theſe blocks, directly under the lines or parts of the figures. Then, with a fine hammer, ſtriking on the metal ſuſtained by the block, the metal yields, and the block makes an indenture or cavity on the inſide; correſpondent to which, there is a prominence on the outſide, which is to ſtand for part of the figure.

Thus the workman proceeds to chaſe and finiſh all the parts, by ſucceſſive applications of the block and hammer to the ſeveral parts of the deſign.

And it is ſurpriſing, with what beauty and juſtneſs, by this ſimple piece of mechaniſm, the artiſts in this kind will repreſent foliages, grotеſques, animals, hiſtories, &c.

ENCHEIRESIS, Εγχειρησις, from εν, *in*, and χειρ, *a hand*, in *Anatomy*, denotes manual operation; as diſſection.

ENCHELIS, in *Zoology*, a genus of *Vermes Infuſoria*, deſcribed eſſentially as being inviſible to the naked eye, very ſimple, and cylindrical. Nearly all the ſpecies are found in ſtagnant water.

Species.

Pyrum. Inverſely conic, behind tranſparent. Müll.

Common in ſtagnant waters, where the duck-weed grows. Body obtuſe, and filled with molecules; and when at reſt, appears to have a ſmall tubercle in the middle of the body. This kind is remarkable for the rapidity of its motion.

Spathula. Cylindrical, ſtriated, with a tranſparent ſpatulate tip. Müll.

Leſs frequent than the laſt, and found in waters in which the duck-weed is infuſed. The body is cryſtalline, and the creature moves in an undulate manner.

Papula. Cylindrical, with the tip papillary. Müll.

Found in the water of dunghills. The body is round, protuberant, opake before, and furniſhed with a papillary finger-ſhaped head; pellucid behind, and both ends obtuſe. Its motion is rotatory and oblique.

Fritillus. Cylindrical, truncated anteriorly. Müll. Hermann.

Met with in water in which graſs or hay is infuſed. The body is pellucid, convex, and obtuſe behind; moves backwards and forwards with a wavering agitation in a line.

Ovulum. Cylindrical-ovate, and hyaline. Müll.

Found in the water of dunghills. Very minute and pellucid.

Fusus. Cylindrical, narrow, and truncated at both ends. Müll.

Obſerved only in pure water.

Epistomium. Elongated, cylindrical, with a ſlender ſub-globular tip. Müll.

Inhabits putrid water. The body is round, obtuſe behind, and its ſize minute.

Seminulum. Cylindrical and equal. Müll.

In water kept ſome days. The body twice the length of its breadth, pellucid before, and opake behind. Moves by alternately aſcending and deſcending.

Nebulosa. Oval-cylindrical, with viſible moveable inteſtines. Müll.

Found in waters with cyclidium glaucoma.

Farcimen. Cylindrical, curved, and truncated at both ends. Joblot.

In water kept a few days. Body opake, and in its motion often appears in the ſhape of the letter S.

Viridis. Green, ſub-cylindrical, and obliquely truncated before.

Abundant in water kept ſome weeks. Tail obtuſe, inteſtines obſcure.

ENCHELUS, Εγχελυς, in *Ichthyology*, the name given by Ariſtotle, Appian, and all the Greek writers, to the eel.

ENCHESON, a French word uſed in our *Law-Books* and *Statutes*, ſignifying the occaſion, cauſe, or reaſon, wherefore any thing is done. Stat. 5 Edw. III. cap. 3.

ENCHRI'STA, from εγχριν, *to anoint*, in *Surgery*, liniments with which parts are anointed.

ENCHYMA, of εγχυω, *I pour in*, in the *Medical Writings of the Ancients*, a word uſed in ſeveral ſenſes. Some have made it expreſs only an *infuſion*; others have uſed it for what the modern phyſicians call *plethora ad vaſa*, that is, a fulneſs of the veſſels, ſimply conſidered, as a relative to themſelves; and others have made it the name of certain forms of liquid medicines, to be injected into the ears, into the thorax, or any other part.

ENCHYMOMA, of εγχυμος, from εγχυω, in the *Writings of the Ancient Phyſicians*, a word uſed to expreſs that ſudden effuſion of blood into the cutaneous veſſels, which ariſes from joy, anger, ſhame, or any other violent emotion of the mind, and is what we uſually call bluſhing; which, according to Dr. Hunter, is a nervous affection.

Enchymoma is alſo an afflux of the blood, whereby the external parts are rendered black and blue, as in the ſcurvy, blood-ſhot eyes, &c.

ENCHYMONITES, in *Natural Hiſtory*, the name of a kind of ſtone found in Macedonia, and ſome other places, which was alſo called *pæonites* and *pæanites*: it was ſuppoſed to be of great virtue to aſſiſt women in labour. See Ceanides.

ENCHYMO'SIS, from εγχυω, *to pour into*, in *Surgery*, an extravaſation of blood from the veſſels, attended with black, blue, or livid appearance of the part. See Ecchymósis.

ENCHYSMA, the ſame with clyſter or enema.

ENCHYTA, in the *Medical Writings of the Ancients*, a name given to ſuch medicines as were injected into the eyes, or into any part.

Some alſo have uſed the ſame word to expreſs a ſort of funnel, contrived to convey the fumes of medicines to any part of the body.

ENCKENDORP, in *Geography*, a town of Germany, in the duchy of Holſtein; 6 miles S.E. of Rendſburg.

ENCKHUYSEN, or Enkhuizen, a conſiderable town of Holland, on the Zuyder Zee, in North Holland; 9 miles N.E. of Horn, and 30 miles N.E. of Amſterdam. N. lat. 52° 40'. Its commerce, and particularly its herring-fiſhery, was of great importance in former times; but its harbour is now almoſt entirely choaked up with ſand.

ENCLAVE', in *Heraldry*, is where one thing is let into another, particularly where the jointure is ſquare.

ENCLITICA, of εγκλινω, *I incline*, in the *Greek and Latin Grammar*, certain particles, united ſo cloſely to the preceding word, that they only ſeem to form one word therewith; and the word which ſuſtains them does generally likewiſe bear the accent that governs them, eſpecially when the enclitic is a monoſyllable; as in *dominuſque*, κυριος τε.

There are three enclitic particles in the Latin, *viz. que*, *ne*, and *ve*; but in the Greek many, as του, μου, μοι, με, σου, σοι, ση, πως, πη, τε, γε, φημι, ειμι, ποτε, and others.

ENCLOS, L', in *Biography*, a muſician in Louis XIII.th's band, an eminent performer on the lute and theorbo, or ſingle and double lute.

He was father of the celebrated Ninon, who played on theſe inſtruments as well as himſelf.

He dying in 1630, left her an orphan at 15 years old, beautiful, full of wit and talents, and formed to inſpire the moſt violent paſſion. Nor did ſhe wrap her talents in a napkin, but availed herſelf of all their influence; and even at more than fourſcore, ſhe is ſaid to have awakened love in the learned abbé Gédoin.

It is pretended that cardinal Richelieu had her firſt favours, and that he was the only one to whom ſhe ſurrendered, without conſulting her inclinations.

She was then 17, and it is certain that, ever after that time, ſhe received a penſion of 2000 livres annually, which was long regularly paid.

Ninon gave concerts at her houſe, where perſons of the firſt rank and talents came to admire her performance on the lute and harpſichord. The philoſopher, Huyghens, the famous aſtronomer, likewiſe obſerved Ninon with great attention and accuracy, and even wrote verſes on her, which Voltaire calls *Geometric*.

> "She has inſtruments five, which my brain much diſturb,
> The two firſt are her hands, the next are her eyes;
> But my tongue for the fifth and the beſt I muſt curb,
> Nor its beauties attempt to diſcloſe, if I'm wiſe."

She was ſeldom left by her lovers, but ſhe left them very ſoon; yet ſhe always retained a friendſhip for her old admirers.

She was ſo celebrated, that Chriſtina queen of Sweden made her a viſit in 1654, in a ſmall villa which ſhe had in the neighbourhood of Paris.

Madame de Maintenon was her beſt friend; and Voltaire aſſerts that M. de Villarceau was a lover in common with both, without its occaſioning a quarrel.

He had two children by Ninon. The hiſtory of the eldeſt is known, who at 19 years old became paſſionately enamoured of her; but on making the diſcovery, he blew his brains out. Her ſecond ſon, called Boiſſiere, died at

Rochelle in 1723, commiſſary of marine. She loved ſeriouſly for ſome time the marquis de Sévigné, brother of madame de Grignan; but who never wrote the letters to her, which M. d'Amoure has printed under her name about 40 years ago.

Madame de Maintenon, becoming all powerful, remembered her, and ſent her word that ſhe would take care of her fortune, if ſhe would change her way of living, and think ſeriouſly of religion: Ninon replied, that ſhe neither wanted fortune nor a maſk. Ninon died at Paris, 1705, at the great age of 90.

ENCŒLIA, of εν, *in*, and κοιλια, *belly*, a word uſed by many of the ancient medical writers, to expreſs the viſcera contained in the abdomen, or lower belly.

ENCOLPIUM, or Encolpion, the pectoral croſs of biſhops, abbots, abbeſſes, &c.; being one of the ordinary marks of the dignity of ſuch perſons both in the Latin and the Greek church.

ENCONDRUS, of εν, *in*, and χονδρος, *grain*, in the *Old Greek Writers*, a word uſed to expreſs any thing made up of a great number of ſmall pieces, or flakes, or ſmall grains of any thing. The manna of the ancients was not in large flakes, as we have it at preſent, but it was formed of a vaſt number of ſmall granules, and was therefore called by Dioſcorides, and ſome others of the Greeks, by this name. The word manna alſo ſignified with them the ſame thing; and they not only expreſſed the ſubſtance by it which we at preſent call ſo, but any other thing that was in ſmall flakes, or pieces, was called manna. Thus the manna thuris, ſo much talked of among the old Greeks, was only a collection of thoſe pieces which flew off from frankincenſe in the breaking. See Manna *Libanotis*.

ENCOPE, of εν, and κοπτω, *I cut*, in *Surgery*, an inciſion of any part; as in a gangrene, &c.

ENCOUNTER, in a *Military Senſe*, relates to that kind of deliberate attack, which is totally abſtracted from accidental hoſtility, and may therefore be conſidered in contradiſtinction to the rencontre, which ordinarily implies a fortuitous meeting. Thus we find, "to lead troops to the encounter," is a very common expreſſion; though we occaſionally hear the term miſapplied by perſons who deſcribe the loſſes, &c. ſuſtained in accidental warfare, as having taken place, not in the rencontre, but in the encounter. We ſhould alſo underſtand, that, in the ſtrict ſenſe, (which relates entirely to the arranging of troops oppoſite, that is, *en-contre*, to the enemy,) we ought not to conſider circuitous attacks, and thoſe feints made merely for the purpoſe of diſtracting the enemy's attention, as coming under this definition; and, on the other hand, we conſider not only thoſe who come into actual engagement, perhaps to the point of the bayonet, as is often the caſe in the attacks made by columns of infantry, but the ſupporting diviſions alſo, to be engaged in the actual encounter. Thus we frequently perceive, that the leading regiment of a column is engaged, while the rear regiments bear no ſhare in the conteſt; but if their ſituations be ſuch as to expoſe them to the enemy's fire, they muſt be as much conſidered in the encounter as a veſſel coming to the aid of another, ſo as to cauſe the enemy's ſhip to ſurrender, or to retreat. Hence it has ever been held a rule, that all veſſels in fight, when a capture is made, become entitled to ſhares in the prize; becauſe, on many occaſions, the approach of reinforcements adds to the vigour of one party, while it depreſſes the ſpirits of the other, and influences it to decline further conteſt.

ENCRANIUM, in *Anatomy*, the ſame with cerebellum.

ENCRASICOLUS, in *Ichthyology*, a ſpecies of clupea. See Clupea and Anchovy.

ENCRATITÆ, formed from εγκρατης, *continent*, in *Eccleſiaſtical Hiſtory*, a ſect of ancient heretics, thus called from their making profeſſion of continence, and abſolutely rejecting all uſe of marriage.

The founder of this ſect was Tatian, a diſciple of Juſtin, and one of the moſt learned perſons of all antiquity. After the death of that martyr, he made a ſeparation from the church, and ſoon had his followers; who, beſide the dogma juſt mentioned, borrowed a great many things from Saturninius and Marcion; beſide ſeveral errors, which they adhered to in common with the Gnoſtics and Valentinians.

They abſtained from eating any thing that had life, and denied that Adam was ſaved. They looked on ſuch as drank wine to be great ſinners; and for this reaſon only made uſe of water in celebrating the Euchariſt, as holding, that wine came from the devil. To countenance this tenet, they produced paſſages out of ſcripture, where mention is made of what befel Noah and Lot, when they were drunk.

They only admitted ſuch of the books of the Old Teſtament as they thought good; but in lieu thereof, they owned ſeveral ſpurious and apocryphal writings for canonical and divine. Such were the Acts of St. Andrew, John, and Thomas.

ENCRAULOS, in *Ichthyology*, the name given by Ariſtotle, and many other of the ancient Greeks, to the fiſh which we call the anchovy. See Clupea and Anchovy.

ENCRINITES, in *Natural Hiſtory*, a kind of columnar extraneous or organized foſſil, found in the earth. See Encrinus, Pentacrini, and Entrochi.

ENCRINUS Fossil, is the remains of an animal, ſo called by ſome; by others, this claſs of zoophytic remains is called *encrinites* (Parkinſon's Organic Remains, vol. ii. p. 153.); and by others, denominated *entrochi*, or *pentacrini*. See thoſe articles. See alſo Harenberg's Encrinus S. Lilium Lap. 4to.

Encrinus, a ſpecies of *Pennatula*, in the claſs of zoophyte worms, comprehending the cluſter-polypi of Ellis, and inhabiting the Greenland ſea.—Alſo, the name given by Ellis to the Aſteria, a ſpecies of Iſis, inhabiting the ocean that waſhes the coaſt of Barbadoes.

ENCRIS, in the *Medical Writings of the Ancients*, ſignifies a ſort of cake made of fine flour, mixed with oil, and ſweetened with honey.

ENCROACHMENT *of the Sea*, in *Geography*, ſignifies the ſudden or gradual converſion of dry land into the verge of the ocean. Hiſtory records numerous inſtances of great and devaſtating effects of this kind: ſome occaſioned by the waves of the ſea undermining the cliffs on its ſhore, and carrying away the matter thereof as faſt as they fall, by which the boundaries of the ſea have been conſiderably enlarged in ſome places; and its ravages ſtill continue with increaſing effect in ſome places, as on the chalky ſhores of Kent and Suſſex. Another kind of marine encroachment, highly intereſting to the geologiſt, is evidently taking place, by ſlow degrees, on a conſiderable portion of the flat ſhores of England; and can only be explained by an exceeding ſlow and gradual ſubſidence of the iſland itſelf, or a correſponding riſe of the ocean which bounds it. This is particularly viſible in the fens and marſhes of our coaſt, which are now defended by banks of that magnitude and height, which ſcarcely any effort of the preſent day could at once effect; but which, as in the marſhes embanked from the Thames below London, muſt have been begun centuries ago, when the tide flowed not ſo high by many feet as it does at preſent, and have been gradually raiſed, as the height of the water increaſed. The finding of immenſe fallen woods of trees, of the recent ſpecies, with the marks of human labour on them, and even the very tools by which they were felled, under great thickneſs of peat, the whole of which is now much below the level to which the tide riſes twice each day, are alſo proofs of this general encroachment of the ſea; ſince neither peat nor trees of any kind will grow where the ſalt-water of the ocean even ſaturates, much leſs continually overflows the ground. The mention of various inſtances of ancient and high embankments of marſhes and fens againſt the tide, will be found under our article CANAL, in the diviſions *Thames*, *Ouſe*, *Welland*, &c. See alſo EMBANKMENT.

ENCROACHMENT. See INCROACHMENT, and ACCROCHING.

ENCURECK, in *Natural Hiſtory*, a venomous inſect, found in Perſia, and ſuppoſed by ſome to be a kind of tarantula. It neither ſtings nor bites, but lets fall its venom like a drop of water, which cauſes inſufferable pain in the part for a time; and afterwards ſo profound a ſleep, that we are told nothing can raiſe the patient from it but cruſhing one of thoſe creatures on the part affected. It is nevertheleſs ſaid, that the ſheep eat theſe inſects without damage. Olearius, ap. Boyle, Works abr. vol. i. p. 37. Ibid. p. 38.

ENCYCLOPÆDIA, the circle or chain of arts and ſciences.

The word is compounded of the prepoſition εν, *in*, κυκλος, *circle*, and παιδεια, *ſcience*, *doctrine*, *diſcipline*, *learning*; the root being παις, *child*, *infant*.

The Greeks uſed the term for the knowledge of the ſeven liberal arts, and the poſſeſſion of all the ſciences. *Orbis ille doctrinæ, quem Græci* εγκυκλοπαιδειαν *vocant*, ſays Quintilian. It is ſometimes alſo written κυκλοπαιδεια, *cyclopædia*. Vitruvius, in the preface to his ſixth book, calls it *encyclios diſciplina*. See CYCLOPÆDIA.

ENCYSTED TUMOURS, in *Surgery*, ſwellings, which are formed of a bag, or cyſt, which is filled with matter very various in its conſiſtence and appearance. When the contents of the cyſt reſemble pap, the tumour is named *atheroma*; when they are of the conſiſtence of honey and wax, it is called *meliceris*; when they are fatty, it is termed *ſteatoma*. See theſe words, and eſpecially TUMOURS.

END *for* END, in the *Sea-Language*. When a rope runs all out of the block, ſo that it is unreeved, they ſay it is run out end for end.

The ſame phraſe is applied to a cable that has wholly run out of the ſhip. In general, it denotes the reverſal of the poſition of any object.

END-*on* is applied to a ſhip, which advances to a ſhore, rock, &c. without any apparent poſſibility of preventing her.

ENDE, in *Geography*, one of the ſmaller Molucca iſlands, S. lat. 8° 30'. E. long. 120°.

ENDEAVOUR RIVER, a river on the N. E. coaſt of New Holland, which at its mouth has a ſmall bar harbour, or creek, that runs in a winding channel three or four leagues inland, and having at its head a ſmall brook of freſh water. There is not depth of water for ſhipping above a mile within the bar. This part of the coaſt is ſo barricaded with ſhoals, as to make the harbour difficult of acceſs, the ſafeſt approach to it being from the ſouthward. S. lat 15° 26'. E. long. 215°.

ENDEAVOUR *Straits*, a channel or paſſage, ſo called by Cook, between New Guinea and New Holland, the N.E. entrance of which lies in S. lat. 10' 39'. W. long. 218° 36'. It is formed by the main, or the northern extremity of New Holland, on the S.E., and by a congeries of iſlands, which Cook called "the Prince of Wales's iſlands" to the N.W., which iſlands probably extend quite to New Guinea. The length of this channel from N.E. to S.W. is ten leagues, and it is about five leagues broad, except at the N.E. entrance, where it is ſomewhat leſs than two miles, being contracted by the iſlands which lie there. The depth of water in the ſtrait is from four to nine fathom, with every where good anchorage, except upon the bank, which lies two leagues to the northward of Wallis's iſlands, where, at low water, the depth is only three fathom.

ENDECAGON, or HENDECAGON, in *Geometry*. See HENDECAGON.

ENDECASYLLABUS, or HENDECASYLLABUS. See HENDECASYLLABUS.

ENDECANDRIA, in *Botany*, from ενδεκα, *eleven*, and ανηρ, *a man*, an order of the Linnæan claſs *Monadelphia*, characterized by having eleven ſtamens, whoſe filaments are, as the character of the claſs itſelf requires, united into a tube. It contains only the genus *Brownea*, the number of whoſe ſtamens is different in different ſpecies, and this preciſe number of eleven is ſo unuſual, and apparently unnatural, in flowers where five and ten ſo much predominate, that perhaps the order in queſtion might be, without miſchief, aboliſhed.

ENDECERES, of ενδηκα, *eleven*, in the *Naval Architecture of the Ancients*, a word uſed to expreſs a galley which had eleven ſeries or tires of rowers. Thoſe with two or three tires were very much in uſe among the ancients, and from thoſe to ſuch as had five or ſix tires. Thoſe of nine tires were ſometimes uſed, but it was very ſeldom; and thoſe of eleven, fifteen, and ſo on, were rather for ſtate, than ſervice. We read of them carried ſo high as to contain twenty, thirty, and forty rows of oars. One of this largeſt ſort was built for Philopater, which required four thouſand men.

ENDEIXIS, Ενδειξις, in *Antiquity*, an action brought againſt ſuch as affected any place or thing, of which they were incapable by law. Pott. Archæol. Græc. lib. i. cap. 23. tom. i. p. 125.

ENDELAVE, in *Geography*, a ſmall iſland of Denmark; eight miles N. of Funen.

ENDEMIC, or ENDEMIAL, *Diſeaſes*, from εν, *in*, and δημος, *a nation*, or *people*, are thoſe diſeaſes which occur among the inhabitants of a particular region or place, in conſequence of certain circumſtances belonging to it, and not ariſing from contagion, or any other general cauſe.

Thus agues, or intermittent and remittent fevers, which are occaſioned by the miaſms of marſhy ground, are *endemic* in low countries: the *goitre*, or bronchocele, connected with that peculiar intellectual imbecility, which characterizes the CRETIN, is *endemic* among the Alps, where its origin has been erroneouſly aſcribed to the uſe of ſnow-water: the colic, COLICA *Pictonum*, is *endemic* in the cyder-counties, eſpecially in Devonſhire: the bilious remittent fever, or yellow fever, is *endemic* in the Weſt India iſlands; and ſo forth. In all theſe inſtances, ſome *local* cauſe obviouſly exiſts, which produces the diſeaſe in the reſpective diſtricts; the diſeaſe belongs to the diſtricts, therefore, and affects thoſe who reſide there, but extends no farther. Whereas an *epidemic* diſeaſe is produced, or at leaſt propagated among the people, in conſequence of ſome general cauſe; as contagion, famine, or, perhaps, ſome change in the condition of the atmoſphere at large.

Hence the diſtinction between endemic and epidemic diſeaſes is obviouſly of great importance, for, in both caſes, much more beneficial purpoſes may be accompliſhed in the way of prevention, than in that of cure. But the prevention of diſeaſes depends altogether upon a knowledge of their cauſes, which ſhould therefore be accurately inveſtigated, whenever they prevail extenſively. If a diſeaſe is endemic, *i.e.* originates in ſome local cauſe, (from marſh effluvia, for inſtance;) it may attack the ſame perſon again and again, while he remains in the ſame ſituation; but he infallibly eſcapes it by removing his reſidence; or the inhabitants of the diſtrict may be all defended from its attacks by draining the marſhy ground, whence the miaſmata iſſue. Thus we are told by writers on the diſeaſes of armies, that the diſorders which ariſe from the foul ground of camps, are readily made to diſappear by removing but a few hundred yards from the ſituation which they previouſly occupied. And of the beneficial effects of attention to the local cauſes of endemic diſeaſes, we have a ſtriking example in the changes, which have occurred in London, in reſpect to the diſeaſes of its inhabitants. In the time of Sydenham and Morton, *viz.* in the latter half of the ſeventeenth century, remittent and intermittent fevers were generally prevalent to a great extent, in the autumnal ſeaſon, and were often extremely fatal to the inhabitants of the metropolis; and the bills of mortality ſhew, that formerly the dyſentery, which almoſt conſtantly appears in the ſame places and ſeaſons as the remittent fever, was annually fatal to great numbers. But of late years theſe diſeaſes have almoſt entirely diſappeared; intermittents occurring only occaſionally after wet ſeaſons, in thoſe people who have viſited the fenny counties during the harveſt; and dyſentery ſometimes prevailing, in a mild way, in thoſe ſeaſons only when the heat has been unuſually great. This exemption, which London now enjoys from thoſe endemic diſeaſes, is chiefly to be aſcribed to the improvements that have been made in the pavement, drains, and ſewers, and the attention that is paid to cleaning and ſupplying with water the ſeveral parts of the town. In ſome towns where theſe precautions are neglected, the remittent fever is ſtill found at times to commit great ravages It is probable that the fever, which proved ſo fatal in Philadelphia, in the year 1793, was of this kind, and produced from the cauſes juſt mentioned. (See Ruſh's Obſervations on the Fever of Philad. 1799. Dr. Miller's Report, New York, 1806.)

Some writers confine the term *endemic* to thoſe diſeaſes which are conſtantly preſent in certain diſtricts, at all times and ſeaſons, ſuch as the *goitre* of the Alps; and call thoſe *epidemic*, which are the product of certain ſeaſons, although originating in a local cauſe, as the autumnal intermittent and remittent fevers of fenny and hot countries. See Epidemic.

ENDENA, in *Geography*, a town of Italy, in the Bergamaſco; ſeven miles N. of Bergamo.

ENDENTED, Dented, or *Indented*, in *Heraldry*. See Indented.

Endented is alſo applied to a feſs or pale, and other triangular pieces, when divided alternately between two different colours. Coupé, or endented with or and azure.

ENDER, in *Geography*, a town of Italy, in the Bergamaſco; 12 miles N.E. of Bergamo.—Alſo, a river of Scotland, which runs into the Garry, ſeven miles W. of Blair-Athol, in Perthſhire.

ENDERSTORF, a town of Sileſia, in the principality of Neyſze; 3½ miles, S. of Ziegenhals.—Alſo, a town in the ſame country and principality; 3½ miles S.W. of Grotkau.

ENDESIS, from εν and δεω, *I bind*, a word uſed by Hippocrates to expreſs that part of the foot where the bones of the tibia end, and which is connected by ligaments to the ankle.

ENDEW, in *Falconry*, is ſaid of a hawk that digeſts her meat ſo well, that ſhe not only diſcharges her gorge of it, but even cleanſes her pannel.

ENDIAN, in *Geography*, a town of Perſia in the province of Chuſiſtan; 150 miles S.S.E. of Suſa.

ENDICA, a word uſed by the alchemiſts for the fæces which ſubſide to the bottom of the veſſels in infuſions; to ſome of which they attribute great virtues.

END-Joints, in *Mining*, otherwiſe called *cutters*, in coal-mining, are the ſhorter of the natural joints or upright partings of any meaſure or ſtratum; the longer of theſe joints being called *Backs*, *Slines*, face or lengthway-joints, or partings: for it ſeldom happens in any quarry or work, that the face-joints are not much longer than the end or croſs-joints.

ENDINGEN, in *Geography*, a town of Germany, in Auſtrian Swabia; ſeven miles N.W. of Fribourg.

ENDINGS of Strata, in *Geology*, ſignify the edges of the ſtrata, in their greateſt advance towards the north weſt, or in the direction of their general *riſe*, according to the obſervations of Mr. William Smith and his followers; by whom it has been obſerved, in all the eaſtern parts of England, that the ſtrata *end* ſucceſſively towards the N.W. generally with a fingered or digitated outline, in ſome, in places running out for miles in ridges, beyond the general range of the edge or limit of the ſtratum: the more recent obſervations in Derbyſhire, at Chelmeſton-low, for inſtance, and other projecting points of ſtrata in that *denudated* diſtrict, ſhew, however, the neceſſity of a careful attention to the fingered or projecting points of ſtrata, and to other concurrent circumſtances, before ſuch fingerings alone are admitted as proofs of the ending of a ſtratum, rather than as part of the edge of a denudated tract, on the oppoſite ſide of which the ſame ſtratum is to be found again, either on the ſurface, or abruptly ſunk beneath it by a fault, and upper meaſures occupy that ſurface. See Denudation, and Concentricity *of Strata*.

ENDITEMENT, or Indictment, in *Common Law*. See Indictment.

ENDIVE, in *Gardening*, the common name of an eſculent plant which is well known in garden culture. There are different varieties of it, but that which is perfectly curled, is the moſt uſeful for culinary purpoſes. See Cichorium.

ENDIVIA, in *Botany*, *Cichorium Endivia* of Linnæus, the garden endive. Ambroſini derives the word from *edendo*, eating, becauſe the plant is ſo grateful to the palate. It appears to us rather a corruption of one of its old names Entyba, or Intuba.

ENDIVIA Marina, the *ſea-endive*, in *Natural Hiſtory*, the name of a ſpecies of ſea plant, or marine ſubſtance, deſcribed by count Marſigli. There are two ſpecies of it, the one having broad and jagged leaves, reſembling thoſe of the vine, the other much narrower. This laſt kind grows on ſtones, ſhells, pieces of wood, or any other ſubſtances, accidentally found at the bottom of the ſea. It ſeldom grows in very deep water, and thrives beſt in places where the ſea is calm and quiet. It is of a duſky greeniſh colour, variegated in ſome places with yellow. It exactly reſembles the ſhape of the endive common in our gardens, and its leaves are cut and fringed in the ſame manner;

but they are of ſo tender a ſubſtance, that a ſlight touch deſtroys them ; they are indeed tenderer and more delicate than thoſe of any other known plant, either of the ſea or land. When this ſubſtance is examined by the microſcope, its ſurface is found to be compoſed of a great number of eminences and cavities, or little holes, between and among them ; and when the leaves are cut tranſverſely, there are ſeen a great number of glandules in them. Marſigli, Hiſt. de la Mer, p. 72. See CORALLINES.

ENDLESS ROLLS, and *Screw*. See the Subſtantives.

ENDOCARPON, in *Botany*, from ενδον, *within*, and καρπος, *fruit*, alluding to the receptacle of the ſeeds being deeply imbedded in the ſubſtance of the leaf, or rather frond. Hedw. Crypt. v. 2. 56. t. 20. f. A. Ach. Prod. 140. Meth. 125. (Lichen ; Zoega Iſland. 15. Dicks. Crypt. faſc. 2. 22. With. v. 4. 52. Sm. Engl. Bot. v. 9. 595, &c.) Claſs and order, *Cryptogamia Algæ*. Nat. Ord. *Lichenes*.

Gen. Ch. *Frond* cartilaginous, rigid, rounded, peltate, depreſſed ; naked beneath. *Receptacles* immerſed in the ſubſtance of the frond, globoſe ; their edges a little protuberant ; their concave diſk lodging the *ſeeds* in vertical cells, and at length expanded and diſplayed.

Eſſ. Ch. Receptacles immerſed, globoſe, concave, in which the ſeeds are imbedded.

This genus is, perhaps, more judiciouſly than moſt ſeparated from the great genus or family of *Lichen*, by Hedwig, followed by the accurate Dr. Acharius. The only queſtion is whether *Verrucaria* ought not to be joined with it, as differing not at all in the parts of fructification, though its frond is a cruſt inſtead of a leaf, juſt as his various *Parmeliæ* differ, even more widely, among themſelves. Several ſpecies of *Endocarpon* are figured in Engl. Bot. t. 593—595. 1512. 1698. 1866. 2012, and 2013. They are ſmall roundiſh or angular plants, commonly growing cloſely preſſed to the earth or ſtone, of a grey or olive hue, their fructification appearing like little black dots over the ſurface.

ENDOR, in *Ancient Geography*, a town of Judea, in the half-tribe of Manaſſeh, on this ſide Jordan, according to the book of Joſhua. Euſebius places it four miles S. from mount Tabor, near Naïm, in the way to Scythopolis.

ENDOR, *Witch of*. See WITCH *of Endor*.

ENDORSE, in *Heraldry*, an ordinary, containing the eighth part of a pale.

This, Leigh ſays, is never uſed but when a pale is between two ſuch : though others hold, that an endorſe may be borne between birds, fiſhes, beaſts, &c. Sir J. Ferne adds, that it ſhews the ſame coat has been ſometimes two coats, and afterwards conjoined within one eſcutcheon, for ſome myſtery of arms. He bears azure an endorſe argent.

ENDORSED, ENDOSSE', is where things are borne back to back.

ENDORSEMENT, of *in* and *dorſum*, *back*, is particularly uſed, in *Commerce*, for a writing on the back of a bill of exchange by the proprietor or bearer, either thereby to transfer it to ſome other, or to render it payable to the order of ſome other, or elſe to ſerve for an acquittance or receipt. See EXCHANGE.

The endorſement is only the name of the proprietor, or endorſer. Note, when the endorſement of a bill of exchange is to render it payable to another, it is called an *order*.

To an order it is neceſſary the endorſement be dated; and contain the name of him who paid the value thereof; in which caſe, the bill belongs to the perſon with whoſe name the order is filed, without any other tradition: without theſe conditions, the bill is judged to belong to the perſon who endorſed it. The bearer of a bill of exchange proteſted has a remedy againſt the endorſers for the payment of the re-change of the places where the bill was negociated by their order. In caſe a bill or note is refuſed to be paid, &c. the bearer has a remedy againſt any one of the endorſers, where there are ſeveral. See BILL.

ENDORSING, or INDORSING, in *Law*, implies the writing on the back ſide of a deed, inſtrument, &c. ſomething relating to the matters contained therein.

ENDOSIS, Ενδοσις, of εν and διδωμι, *I give*, in the *Medical Writings of the Ancients*, a word uſed to expreſs a remiſſion of any kind, as when a tumour, inflammation, or hardneſs of any part, becomes leſs violent ; and when the patient becomes eaſier, after the exacerbations in fevers of the continual kind, and after fits of the intermittent.

ENDOWMENT, or INDOWMENT, the giving or aſſigning of a dower to a woman. See DOWER.

The word is alſo uſed figuratively, for the ſetting forth or ſerving a ſufficient portion for a vicar, towards his perpetual maintenance, when the benefice is appropriated ; whence ſuch a vicarage is called a vicarage endowed.

ENDRACHIUM, in *Botany*, Juſſ. 133, ſee THOUINIA. The name is barbarous, corrupted from the Madagaſcar word Endrach, under which it occurs in Lamarck's Encycl. v. 2. 356, who nevertheleſs calls the genus *Humbertia*, following Commerſon. See Lamarck's plates, t. 103. Dr. Smith named it *Thouinia*, and is followed by Schreber, Willdenow, and Martyn.

ENDRAPA, in *Ancient Geography*, a town of Aſia, in Meſopotamia, ſituated on the left bank of the Euphrates.

ENDSCHUTZ, in *Geography*, a town of Germany, in the circle of Upper Saxony, and circle of Neuſtadt ; 4 miles E.N.E of Weyda.

ENDYMATIA, in *Antiquity*, a kind of dance uſed among the Greeks, performed in Arcadia, to the ſound of certain airs compoſed for the flute.

ENEDA, in *Geography*, a town of Switzerland, in the canton of Glaris ; 2 miles E. of Glaris.

ENELIAXIS, Ενηλιαξις, or rather *Enyaliaxis*, Ενυαλιαξις, in *Antiquity*, a feſtival in honour of Enyalius, whom ſome will have to be the ſame with Mars, others only one of his miniſters. Pott. Archæol. Græc. lib. ii. cap. 20. tom. i. p. 394.

ENEMA, of ενιημι, *I put in*, in *Medicine*, denotes a clyſter. See CLYSTER.

ENEMY. See ALIEN.

ENEOREMA, of εναιρεω, *I lift up*, is uſed by ancient medical writers for thoſe parts of the urine which float about in the middle reſembling a cloud, formed, according to Boerhaave, principally of muriatic ſalt. Comm. Inſtit. § 382.

ENEOS, of εν and αυω, *I cry*, a word uſed by the ancient writers in *Medicine*, for a perſon born deaf, or unable to perform the common offices of life, for want of any of the principal organs.

ENERGETICAL BODIES or *Particles*, are ſuch as are eminently active, and which produce manifeſt operations of various natures, according to the various circumſtances and motions of ſuch bodies or particles.

ENERGICI, in *Eccleſiaſtical Hiſtory*, an appellation given to certain diſciples of Calvin and Melancthon, of the ſixteenth century, becauſe they held the Euchariſt was the energy and virtue of Jeſus Chriſt ; not his real body, nor a repreſentation thereof.

ENERGUMENUS, Ενεργουμενος, a term ſometimes uſed by divines and ſchoolmen, to ſignify a perſon poſſeſſed with a devil, or an evil ſpirit.

The word is formed from the Greek, ενεργεισθαι, *to be agitated, worked*, of εν, and εργον, *opus*.

Though Papias ſays, the Energumeni were ſuch as counterfeited the actions of the devil, performing things which ſeemed ſupernatural. The council of Orange debars, or deprives the Energumeni of the functions of the prieſthood. See Dæmoniac.

ENERGY, in *Elocution*, a mode of delivery applicable to particular paſſages of a diſcourſe that are meant to be rendered particularly impreſſive and operative upon the feelings and convictions; like emotion, if not too frequently appealed to, or too extravagantly exerted, it has a great tendency to demonſtrate the ſincerity and real earneſtneſs of the ſpeaker; which is always one of the indiſpenſible requiſites for the conviction of the hearer. In declamation it ſhould be manifeſted alike in the enunciation, the tones of the voice (which ſhould be firm and fervid), and in the geſticulation. It is this quality in the ſpeaker that ſeems to have been deſignated by Demoſthenes as the firſt, ſecond, and third requiſite of an orator. Action (Ενεργεια, the Latin *actio*,) not being confined in ſignification to the mere motion of the limbs, but to the entire and reciprocal exertion of the mental and organic faculties of the ſpeaker, the co-operative energy of thought, language, enunciation, tone, look, geſture, and deportment. "Et actio oratoris pronunciatio ac geſtus, & ipſa adeo adminiſtratio cauſſæ." Cic. in Orat. c. 17. "Oratorical action is pronunciation and geſture; hence the very delivery of the ſubject." "Eſt actio quaſi corporis quædam eloquentia, cum conſtet e voce et motu." Quintil. Q. 3. "Action is, as it were, a certain eloquence of the body, conſiſting in voice and motion." See alſo Geſner's Theſaurus in voc. actio.

Energy, in *Painting* or *Sculpture*, may be divided into two parts, *viz.* energy of thought, and energy of execution.

The former conſiſts in deeply inveſtigating the nature and intereſt of a ſubject, and ſelecting that moſt impreſſive and deciſive moment for repreſentation (and alſo the mode of doing it) which ſhall convey to the imagination of the beholder with the greateſt intereſt, either its hiſtory or its moral.

The latter conſiſts in that ſame active, animated ſpirit, being accompanied by the power of diſplaying the repreſentation of that ſelection, either on marble or on canvas, with force, with freedom, and preciſion; without labouring, at leaſt without leaving the appearance of labour, in endeavouring to obtain its expreſſion.

The compariſon of two artiſts who in their works have each reſpectively exhibited the poſſeſſion of theſe two qualities in the higheſt degree, will beſt illuſtrate our meaning.

Raphael's works are full of energy of thought. Thoſe of Tritoretto of energy of execution.

The former always fixes upon that preciſe moment of time in a ſtory which is moſt favourable for relating it with ſucceſs; and is ſure to intereſt by the force and truth with which he unfolds the circumſtances of it. He ſometimes even, and that with the greateſt propriety, goes farther than the mere relation of the particular ſubject; he accompanies and illuſtrates it by alluſions to antecedent and ſubſequent events connected with it; as in the cartoon of the death of Ananias.

In that picture, ſome of the diſciples on the right of St. Peter are ſtill engaged in diſtributing alms, not yet having obſerved the inſtantaneous puniſhment inflicted by Almighty vengeance on the guilty ſinner; we are thus unaffectedly informed of the object for which the apoſtles are aſſembled, and how they were engaged previouſly to the time of the immediate ſubject of the work, and we are led as ſimply to underſtand ſomewhat of that which followed, by the introduction of the figure of Sapphira; who advances on the oppoſite ſide, intent upon counting the money ſhe may be ſuppoſed propoſing either to give to the fund devoted to charity, or to withhold, that ſhe might gratify her own, and her now dying huſband's avarice; whoſe fate, of which ſhe appears to be altogether unapprized, ſo nearly awaited herſelf, for her deſign of committing the crime for which he was ſo awfully puniſhed.

Thus we ſee, that no part of the intereſt of the ſubject eſcaped the active energy of the mind of Raphael, and many others of his works would as well illuſtrate his great ability in this point of the art; *e. g.* the cartoon of St. Paul preaching at Athens, but in neither of theſe noble works is there much energy of execution: that was the *forte* of Tintoretto.

He ſeldom ſtopped to think correctly and refinedly upon his ſubject. He rarely pourtrays the paſſions with truth in the countenances of his figures, or gives his ſtory intereſt on the mind; except by the aſtoniſhing freedom, force, and fire of his pencil in the execution, where it appears to have moved with the utmoſt rapidity; the canvas trembles under it. His vigour in colour equals the ſkill of his workmanſhip; and theſe united, the obſerver forgets the want of more valuable beauties. The ſkill of the maſter ſtrikes more than the work itſelf. His execution well deſerves the appellation beſtowed upon it by the Carracci, "Il terribile maniera del Tintoretto." It ſtill remains a deſideratum in art to ſee it united with elegance of deſign; with feeling, and truth in thought, and expreſſion.

In ſculpture the author of the Laocoon has effected their union. We may, therefore, hope its ſiſter art may ſometime arrive at an equal degree of perfection. But there are ſo many more points of difficulty to overcome in painting than in ſculpture, that he muſt be almoſt ſuper-human who effects it.

Many will rather wiſh that Michael Angelo had been inſtanced as poſſeſſing energy of thought in preference to Raphael; and juſtly he might have been hailed as a wonderful model of it, as he alſo was to a conſiderable degree in the other acceptation of the word, *viz.* in execution. But his energy is leſs underſtood than that of Raphael; and is of a leſs valuable kind; as it not unfrequently renders his figures enigmatic, and nature is loſt in art. Raphael comes equally with him, home to his ſubject; and can ſcarcely ever be miſunderſtood. Hence, therefore, we think ourſelves juſtified in preſenting the latter to the attention of our readers rather than the former; not as willing to depreciate Michael Angelo; but becauſe we conceive, that while the conſideration of his energetic powers may invigorate the ſtudent, it may divert his mind from truth, and lead him to bombaſt and affectation; which the contemplation of the works of Raphael never can do, unleſs he be of a moſt perverſe ſtamp of nature indeed. If energy of thought may be ſaid to be characterized by thoſe ſtrong workings of the imagination alone, which produce the repreſentation of the moſt extraordinary and powerful actions of the human body, with bold fore-ſhortenings and ſtrong expreſſions; then M. Angelo claims by far the higheſt place, but we do not conceive that to be the beſt criterion for judgment on this point. He who ſees cleareſt, and while he gives it powerfully, moſt juſtly and beautifully illuſtrates his ſubject, muſt ſurely have as fully and warmly conceived the nature of it; as he, who, mixing the extravagance of enthuſiaſm with his energies, permits his mind to run wild upon it; and throws upon his canvas figures which rather confuſe than exemplify, and draw the attention of the obſerver from the ſubject to the painter. This enthuſiaſm, we think, does characterize in a great meaſure the wonderful works of M. Angelo; whilſt Raphael's mind, though full of energy, is pure, and going to the extreme of indulgence in his ſubject, ſtill keeps within its bounds.

ENERVATING, the act of deſtroying the force, uſe, or office of the nerves, either by cutting them, by weakening them with debauchery, or by ſome other violence.

Exceſs of wine, and other ſtrong, hot, ſpirituous liquors, enervate or weaken the nerves. When they would render a horſe uſeleſs, they enervate him, or cut his nerves.

Enervating, is particularly uſed in the *Manege*, for the cutting two tendons on the ſide of a horſe's head, under the eyes, which meet on the tip of the noſe; they thus enervate horſes, to make their heads ſmall and lean.

The word is alſo uſed figuratively. It is no ſmall artifice in diſputing, to be able to enervate and extenuate the allegations of one's antagoniſt. This author has a weak enervate ſtyle. See Nerve.

ENERVATION, a term in the *Ancient Anatomy*, applied to the tendons of the recti, or ſtraight muſcles of the abdomen.

The fibres of the recti of the abdomen do not go from one extreme of the muſcles to the other, but are interſected by ſeveral nervous places, called by the ancients enervations, though they be real tendons.

Their number is not alike in all; ſome having three, others four, &c.

ENERVE, Folium, in *Botany*, a leaf deſtitute of ribs and nerves. See Leaf, and Costatum Folium.

ENFANS Perdus, a French phraſe, uſed in war to ſignify the ſoldiers who march at the head of a body of forces appointed to ſuſtain them, in order to begin an attack, make an aſſault, or force a poſt.

The word literally imports *loſt children*, on account of the imminent danger they are expoſed to.

In Engliſh, they are called the *forlorn*, or *forlorn hope*.

At preſent, the grenadiers uſually begin ſuch attacks.

ENFIELD, William, in *Biography*, was born at Sudbury in the year 1741, and educated for the miniſtry among the Proteſtant diſſenters at the academy at Daventry, where he diſtinguiſhed himſelf by the poliſh of his early compoſitions. He was firſt ſettled as miniſter with the congregation at Benn's garden, Liverpool; this was in the year 1763; and, in 1770, he became reſident tutor and lecturer in the belles-lettres in the academy at Warrington. He ſhortly after qualified himſelf as mathematical tutor, and in that character publiſhed "The Inſtitutes of Natural Philoſophy," in quarto. A new edition of this work was publiſhed after the doctor's death, with conſiderable additions, and an introduction to the modern doctrines and diſcoveries in chemiſtry. It may be reckoned one of the beſt popular introductions to Natural and Experimental philoſophy. During his labours at Warrington, which were highly prized, the univerſity of Edinburgh conferred upon him the title of doctor of laws. In the year 1785, he removed to Norwich, and became paſtor of the congregation of diſſenters in that place. With the duties of this office, he ſucceſsfully employed himſelf in various literary undertakings, among which was the laborious taſk of tranſlating and abridging "Brucker's Hiſtory of Philoſophy," a work to which we have frequent occaſion to refer in the courſe of our own inveſtigations of the learning of ancient times. This abridgment was publiſhed in two vols. 4to. in 1791, and "probably," ſays his friend and biographer, Dr. Aikin, "the tenets of the different ſects of philoſophers were never before diſplayed with ſo much elegance and perſpicuity. It was, indeed, his peculiar talent to expreſs the ideas of other men to the greateſt advantage. His language, chaſte, clear, correct, and free from all affectation, is one of the beſt ſpecimens of that middle ſtyle which is fitted for all topics, and he communicates to his reader all that clearneſs of idea which reigned in his own mind. Theſe qualities, together with the candour and moderation which made part of his very conſtitution, eſpecially fitted him for the office of literary criticiſm, and he was long an aſſociate in one of the moſt reſpectable of the periodical journals." He died November 3d, 1797, in the 57th year of his age, generally beloved and lamented. In every relation of life, the benevolence of a kind heart diſplayed itſelf in the moſt engaging features. He publiſhed "Sermons," "Family Prayers," and "The Preacher's Directory." His compilations, entitled "The Speaker," and "Exerciſes in Elocution," are perhaps the moſt popular works in our language, and they unqueſtionably merit the patronage which they have had, and continue to have. After his death three volumes of his ſermons were publiſhed by ſubſcription, and the numerous friends who patronized this work, will prove the attachment which he had inſpired. Gen. Biog.

Enfield, in *Geography*, a town and pariſh in the hundred of Edmonton, and county of Middleſex, England, is ſituated nine miles from London, and contained, according to the late return to parliament, 926 houſes, inhabited by 5881 perſons.

It is ſtyled in ancient records Enfen, or Infen, from its fenny ſoil, which is now, however, converted into good land, by draining, &c. The pariſh is very extenſive, the town itſelf being but a ſmall part of what bears the name of Enfield. The pariſh church is an ancient ſtructure, and has been recently repaired. Here are a good free ſchool, and two meeting-houſes for diſſenters. Part of an ancient royal palace ſtill remains, where Edward VI. is ſaid to have reſided, and where queen Elizabeth kept her court in the early part of her reign. One of the rooms appears in its original ſtate, with oak pannels, and a richly ornamented ceiling: the chimney-piece is of admirable workmanſhip, and decorated with the arms of England and France quartered. The palace was alienated from the crown by Charles I. and has ever ſince been private property. In 1670 it was taken by Mr. Uvedale, maſter of the grammar-ſchool, who, being attached to botanical ſtudies, planted in the garden a cedar of Libanus, which, in 1793, meaſured twelve feet in girth, three from the ground. The town had formerly a good market, which is fallen into diſuſe. In the ſuburbs are a number of boarding-ſchools, and ſeveral elegant villas. Enfield was heretofore much celebrated for its *Chaſe*, which comprized a large tract of woodland, well ſtocked with deer; but during the civil war it was ſtripped both of game and timber, and let out into ſmall farms: after the reſtoration it was again laid open, woods planted, and filled with deer. In 1779 it was diſafforeſted by act of parliament; parcels were allotted to different pariſhes, and the remainder ſold. A part was bought by Dr. Jebb, who having ſucceſsfully attended the duke of Glouceſter at Trent, the king, on conferring the dignity of baronet on him, gave the name of Trent-place to the villa which he had erected here. South Lodge, alſo on the chaſe, was the favourite retirement of the late earl of Chatham. Eaſt Lodge was the hunting ſeat of Charles I.

In this pariſh, at a place called "Four-tree hill," or Forty-hill, the late Richard Gough, eſq. had a ſeat, where he died, in February 1809. Some account of this eminent topographer and antiquary will be given in a ſubſequent part of this work. Lyſon's Environs of London, vol. ii.

Enfield, a townſhip of America, in Hartford county, Connecticut, on the eaſt bank of Connecticut river, oppoſite to Suffield, and bounded on the north by the Maſſachuſett's line; ſettled in 1681. In 1769 it contained 214 Engliſh families. In the town are two congregational churches, and a meeting-houſe for the ſect called Shakers. The town is pleaſant, and contains 1761 inhabitants; 18 miles N. of Hartford.—Alſo, a townſhip in Grafton county, New Hampſhire, about 11 miles S.E. of Dartmouth college; incorporated in 1761, and containing 1121 inhabitants.

ENFILADE, a French term, ſometimes uſed in Engliſh, ſignifying a ſeries or continuation of ſeveral things, diſpoſed, as it were, in the ſame thread or line; as an enfilade of rooms, of doors, of buildings, &c.

The word is formed of the French verb, *enfiler*, to ſtring a thing, which is compounded of *en*, *in*, and *fil*, of *filum*, thread; *q. d.* a thread or ſtring of any thing.

Enfilade, in *Military Matters*, relates to a certain mode of acting upon the defenders of lines, redoubts, batteries, &c. thereby counteracting the impediments thrown in the way of a direct fire. To explain this, it is neceſſary to obſerve, that defences may be attacked in three modes; *viz.* *direct*, that is, by a reſponſive fire in front, or, at leaſt, ſo little obliqued as to come under the general acceptation of what the French engineers term *fiſhant*, or, plunging: this fire is commonly at right angles with the line of defence to be battered: when the fire is much obliqued, it is ſaid to be *razant*, or grazing. The ſecond mode of attack is by *reverſe*; that is, where the batteries of the beſiegers can be ſo directed as to command the interior of the rampart, and thus render it impoſſible for the defenders to remain at their guns. This mode generally relates to an angle of at leaſt fifteen degrees from the line of the defence in queſtion, but may extend to any angle up to 90°; remarking, however, that the more direct the fire may be in reverſe, the leſs execution will be done, becauſe the ſhot can only ſtrike one particular object. The third mode is by *enfilade*, and is always the moſt deſtructive, eſpecially if the guns of the enfilading battery can be brought to bear at a right angle with the direction of the battery to be enfiladed. When this cannot be effected, it is neceſſary to make a ſmall angle in reverſe, the leſs the better, thereby to throw the ſhots along the interior of the parapets, and to take the whole in flank. Some fortreſſes are unavoidably ſo ſituated as to have one, or perhaps two batteries expoſed to a very diſtant enfilade. Such a defect is of the utmoſt importance, and cannot be radically overcome; for we ſometimes ſee ſome hill, or what is worſe, ſome ſhifting ſand, which cannot poſſibly be either removed or occupied, but which affords both a command, and a lodgment in ſecurity from the fire of the place. Although this is aſſuredly an immenſe drawback on the ſtrength of the works, it is nevertheleſs in ſome ſituations of little moment; for inſtance, where it is neceſſay to retain a ſmall force for the purpoſe only of preventing an enemy from landing at the only acceſſible ſpot upon a long range of coaſt, preſenting in every other part ſuch natural obſtacles as annihilate all apprehenſions of invaſion. In ſuch place the ſurrounding eminences are of no moment; or if they were, muſt rather be conſidered as offering advantages, and the means of rendering the place untenable to the enemy, ſhould they ſucceed in carrying the works.

Speaking generally, however, a fortreſs that can be enfiladed with tolerable ſafety to the beſiegers muſt be untenable; becauſe it is impoſſible to deviſe effectual means for remedying the evil. It is true, we may raiſe large epaulements, or buttreſſes of ſoil, maſonry, &c. for the purpoſe of preventing the enemy's ſhot from ranging along the rampart; but, in moſt inſtances, where enfilades can be made, theſe epaulements would require to be carried to ſuch an immenſe height, as muſt, in a meaſure, deteriorate the other defences; in ſome inſtances rendering them nugatory, or even advantageous to the aſſailants, whenever they may be able to make a lodgment. Beſides, ſuch epaulements are very liable to be deſtroyed by mortar and howitzer batteries, or by mines. This mode of parrying the enfilade has, with much propriety, been of late years deſignated by the French engineers a *defilade*, a term peculiarly expreſſive of the intention of whatever devices may be uſed for the purpoſe of preventing defences from being enfiladed. It muſt not be forgot, that the approaches of beſiegers ſhould be carefully conſtructed; elſe they may be ſubjected to enfilade from ſome of the defences. That evil is, however, eaſily avoided; and if, through ignorance or inadvertence, found to take place, may be inſtantly corrected, as the beſiegers have, on almoſt all occaſions, ample range for alteration, and can adopt a variety of meaſures totally unattainable to thoſe within the fortreſs.

Where a work is carried over a riſing ground, it is generally very difficult to render the interior of the batteries ſafe from either reverſe or enfilade. The beſt mode is to carry them up the aſcent *en eſcalier*, that is, by ſhort levels, each perhaps capable of mounting four or five guns, and every ſuch level being cut off from its neighbour below, by a heavy epaulement, carried up high enough to prevent the beſiegers from trundling their ſhots along within the parapet. The moſt effectual method of cutting off enfilades is to give the rampart ſuch an augmentation of thickneſs as may allow a free paſſage for cannon, &c. along the rear of thoſe in the embraſures, and to fill up the ſpaces between the latter with *traverſes*, carried to at leaſt ten feet in height. Theſe traverſes are nothing more than regular maſſes of ſoil, properly turfed, or perhaps reveted with maſonry, placed at right angles with the parapet, and uniting therewith: their thickneſs ought not to be leſs than ten feet.

We muſt here obſerve, that with few exceptions, the enfilade commonly takes place from the exterior flank of the battery; therefore that quarter ſhould be chiefly attended to. With this view it is found moſt proper to conſtruct each traverſe partly of maſonry, and partly of ſoil well gazoned, (*i. e.* turfed) or, if on emergency, firmly retained by faſcines. Sometimes ſand bags will be found to anſwer for this part, when the reſidue of the thickneſs is completed with good maſonry, at leaſt four feet in ſubſtance. Where cotton, or wool, or raw hides, are procurable, they will be found to make admirable traverſes, if ſuſtained by a firm wall: theſe being placed neareſt to the enfilading quarter, will, by their elaſticity, completely deaden the force of the ſhot, however great their calibres, and cauſe them, if they ſhould reach ſo far, to be weak and inſignificant in their impreſſion upon the interior buttreſs of maſonry. It ſhould ſeem, to perſons unacquainted with the practice of defending places, that, in conſequence of the great reſiſtance offered by ſolid maſonry to cannon-ſhot, which will often bury themſelves full fifteen feet, or more, in ordinary ſoil, the traverſes ſhould be conſtructed of maſonry only: this would, no doubt, preſent great firmneſs in a contracted ſpace; but the inconceivable deſtruction and diſmay occaſioned by the ſplinters knocked off by ſhots that ſtrike upon bricks or ſtones, oppoſes an inſuperable bar to what would otherwiſe prove a moſt valuable mode of conſtruction; ſuch, indeed, as would render many places abſolutely impregnable. This compels us to reſort to ſuch materials as are, in a great meaſure, devoid of ſuch miſchiefs, of which turf is the beſt.

It is generally conſidered, that the enfilade is cut off by placing traverſes at from fifteen to twenty toiſes aſunder; but the latter diſtance, (equal to forty yards,) is certainly too great: it would even be adviſeable to bed the guns between traverſes, as we have above ſhewn, were it not that by ſo doing the battery muſt be weakened, owing to the ſpaces occupied by ſo many buttreſſes. However, neceſſity and, generally ſpeaking, locality, muſt give laws for the conſtruction of ſuch impediments to the enfilades. It muſt be underſtood, that the obnoxious battery may be very powerful; that is, it may not only mount heavy cannon, but may be far more numerous than might at firſt be ſuppoſed. To explain this, it muſt be ſtated that the moſt deſtructive enfilade is that which ranges along the interior of a battery, at about from two to ſix feet within the parapet; ſince in that direction it is ſure to deſtroy not only the defenders, but even the cannon, diſmounting them, and cruſhing the gunners, as well as cauſing a variety of ſplinters to ſcatter among them, from the ſeveral parts of the wood and iron work. Sometimes, indeed, when the ſhots touch upon the cannons themſelves, the former, being of caſt iron, and conſequently liable to ſhiver when forcibly ſtruck, break into numerous pieces, or even fracture the latter, ſo as to render them perfectly unſerviceable.

If ſhots were to be fired at ſuch an elevation as barely to graze the creſt, or ſummit, of the parapet, they would certainly prove moſt deſtructive to the defence flanked by ſuch a forcible fire; but this cannot be effected at ſhort diſtances, ſince, it is evident, the ſhots would, at the moment of touching the creſt of the parapet, be *aſcending*, and that too with ſuch force as could not fail to impel them far over every part of the fortreſs, and thus to prove completely unavailing. This mode of enfilade, therefore, commonly takes place where the cannon is not at leaſt on a level with the creſt of the parapet, ſo as to ſend its ſhot through it with ſufficient force to cut clean through, without being thrown upwards into a new direction, and thus to plunge into the more remote part of the defence. When the enfilade is more diſtantly ſituated, the ſhots may certainly be thrown over the parapet as they are *deſcending* upon their long range; but this is very uncertain, and rarely does much execution; to be ſure, when the ſhots can be correctly thrown, the havoc they create is dreadful.

The uſual mode of enfilading is by ricoçhet, that is, by giving the piece, whether mortar, howitzer, or cannon, ſuch an elevation, and ſuch a charge, as may cauſe the ſhot to bound firſt on the glacis, and then over the rampart into the battery. This, our readers will perceive, is exactly on the principle of "a three-quarter ball" at cricket; which, if it paſſes over the wicket, makes ſeveral low bounds, or, as they are technically termed, "lobs," in proceeding along their courſe, until they come to a ſtate of reſt. So does a cannon-ſhot, after bounding over a rampart, keep lobbing, rather more forcibly indeed than a cricket-ball, along the terre pleine of the rampart. It will not be neceſſary to expatiate on the effects of this dreadful contrivance, they being ſo obvious, and ſo completely ſimilar to what is called "raking fore and aft," in naval warfare.

The moſt powerful ricoçhet takes place at an angle under ten degrees of elevation; fifteen degrees are the utmoſt that are allowed, both becauſe the effect produced is leſs when the elevation is encreaſed, and the gun-carriage is proportionably injured by the direction of the recoil deviating from the horizontal, ſo as to depreſs and ſtrain the hinder parts of the frame work; while, at the ſame time, the wheels are lifted in the fore part, and return to the ground with undue force. When mortars are uſed in ricoçhet firing, they are commonly charged with a number of ſhots, or of ſhells, forming in the whole, what we may term, a round of grape proportioned to the calibre of the piece. In batteries intended ſolely for ricoçhet firing, the embraſures ſhould have their ſuperior ſlope outwards, as ſeen at K in the plate; whereby the enemy could not fire into it ſo eaſily as if the embraſures were made in the uſual way: in fact, they could not diſtinguiſh them, as the whole would be nearly ſolid, much the ſame as a mortar-battery. Where infantry or cavalry are to be fired at in ricoçhet, the pieces muſt not be elevated more than three degrees, otherwiſe their greateſt effect would not be produced. Ships may likewiſe be acted upon by ricoçhet, if the ſhots are cauſed to ſtrike the water at a *depreſſed* (inſtead of an *elevated*) angle of about four degrees, ſo as to touch the ſurface at from two hundred to two hundred and fifty yards from the battery. But this applies only to particular caſes; for if the veſſel be remote, or that any object is to be fired over, the ſame angle of elevation may be uſed, taking care ſo to proportion the charge, that the ſhot may light upon the water at about two hundred yards from the veſſel, if ſhe be large; but if ſmall, the ſhot muſt light nearer to her, in proportion to her want of bulk.

It was neceſſary to ſay thus much of ricoçhet firing, in order to give a complete inſight into the manner of enfilading by means of ſmall charges of powder. The reader will likewiſe perceive that ſeveral guns may enfilade the ſame battery, in exactly the ſame line, merely by cauſing them to be removed farther from the object of attack, the one behind the other, only taking care that the parapet before each be ſufficiently ſubſtantial to prevent accident to the other batteries in its front, and cauſing the more remote to charge higher, in order that their ſhot may be thrown ſufficiently far to make the firſt bound in a proper manner, over the epaulement of the defence to be enfiladed. We ſhould obſerve that the mode of enfilading before-mentioned, namely, by grazing directly over the creſt of the parapet, may be extended to remote works; but unleſs they are manned for action little damage will be done, as the beſieged will rarely fail to *houſe* their cannon, by pointing them towards the enfilading-battery; ſo that they may be far leſs expoſed than when ſtanding in their proper directions.

We ſhall annex to this article, which we have dwelt upon in deference to its importance in military affairs, a few general principles. 1ſt. That the deſcending enfilade is the moſt deſtructive in long ranges. 2dly. That the ricoçhet-enfilade is peculiarly adapted to ſhort diſtances. 3dly. That the angle ſhould, if practicable, be kept under ten degrees of elevation; the greater effect being generally in proportion to the leſs deviation from the horizontal direction. 4thly. That the more direct the fire may be along the line, or defence, to be enfiladed, the greater will be the damage done thereto, provided it be within ſuch a parallel with the parapet as may ſubject both the cannon and the gunners to its range. 5thly. That if any angle is to be made with the line to be enfiladed, a few degrees in reverſe are better than even half their number in advance; becauſe, though the former may not ſtrike any object in its original courſe, the ſhots may, after having grazed againſt the interior of the parapet, *genouillere*, &c. ſtill do conſiderable damage; and, even though they ſhould not either diſmount a cannon, or kill any of the men on the battery, they muſt tear the garon-revetement far more than one of maſonry, which is often put exteriorly, though not within: the latter would turn the ſhots off, in all probability, and cauſe them to have only the effect of a weak fire *razant.* 6thly. It will be neceſſary to aſcertain the thickneſs of the parapet behind which the enfilading ſhots are to trundle: in common fortifications it may ſufficce to compute, as nearly as may be practicable, upon about four toiſes, (or eight yards,) from the extremity of the ſuperior ſlope of the angle; but in places where the parapets are made of maſonry, leſs will commonly be neceſſary, for the purpoſe of ſtriking ſomewhere upon the line of platforms, and of thereby diſmounting the cannon. 7thly. Where howitzers are uſed for the enfilade, the traverſes muſt be very numerous, to prevent the pieces of burſten ſhells from ſpreading to any extent. But, in ſuch caſe, the traverſes will not require ſo much ſolidity, as if oppoſed to heavy ſhots. 8thly. Where a remote battery is to be enfiladed, eſpecially if the enfilade be direct, that is, in a line with the prolongation of ſuch battery, great care muſt be taken to be exact in aſcertaining its diſtance from that part of the defences which may be neareſt to the enfilading party. This may, in general, be done, with preciſion, by means of two long ladders placed face to face, and elevated during the night, ſo as to give a command of the works then in a ſtate of actual oppoſition; when the flaſhes from their cannon will prove a ſufficient guide. This may, however, be done with more preciſion during the day time, though certainly with more danger; but the operation being certain and ſpeedy, compenſates for the riſk. The enfilade on ſuch occaſion muſt not be by ricoçhet, but by deſcent. Thoſe who are in front of the enfiladed battery, or nearly ſo, will ſee the effects of the ſhots, and can, by means of pre-concerted ſignals, give information accordingly to the enfiladers.

The following references to the figures in *Plate* III. *Fortification, fig.* 1, will explain more fully what has been ſaid.

Let A B be the face of a baſtion, whoſe ſaliant or flanked angle, B, is battered in breach from C C. In ſuch caſe, the beſieged muſt make a very ſtrong epaulement from B to P, on the adjoining face, to prevent the ſhots from the enfilading battery at D trundling upon the terre-pleine of the face A B; in aid of this reſiſtance, the traverſes, S, S, S, muſt likewiſe be thrown up. The battery at D being a direct enfilade, that is, in the line of the face A B, is highly deſtructive; while that at E, which is only 15° in reverſe, is far leſs ſo. It is indeed evident, that one cannon at D would be more effectual than two at E; unleſs the ſhots from the latter ſhould be thrown in ſo as to fall upon the neareſt part of the interior of the parapet, as has been already implied: they would then be capable of tearing away the interior of the merlons, and of cauſing great numbers of ſplinters, &c. The battery at F is a direct-enfilade of the face of the remote baſtion H; but its fire muſt not be in ricoçhet, (as that could never reach its object,) but by deſcent. At I, an enfilading battery is ſhewn in profile, the cannon being ſunk, and the embraſure, K, having an inverted ſlope, covering the cannon from the fire of the battery at L. This ſlope being only 10°, admits the ſhots from the cannon to aſcend, by means of a ſmall charge, in a curve meeting the ground at N; thence reaſcending over the face L. (correſponding with B P in the upper figure,) ſo as to light again at O, upon the terre-pleine of the face M, (here ſeen in reverſe, and correſponding with the interior of A B in the upper-figure;) whence it will again riſe, and, if unimpeded, bound on in ſucceſſively diminiſhing curves, until its force be expended. The dotted line, from the cannon I to O, on the baſtion M, ſhews the direct or plunging enfilade by deſcent, which is beſt adapted to cannon of a ſmaller calibre; the force of the ſhot being, in this inſtance, unabated by any bound; as muſt be the caſe in ricoçhet, wherein, by ſtriking at N, the impetus is conſiderably diminiſhed. This diminution will be greater, in proportion as the elevation of the cannon is increaſed. As already ſtated, the enſilade of H from F will be of little moment, unleſs the battery at H be in action; but, as the obliquity of the embraſures may enable the enfiladers at F to act either in ricoçhet, or by deſcent into the reverſe of A C, or even of A B, there might be conſiderable advantage gained by ſuch a poſition. It is proper to ſtate, that this does not appear to be generally practicable; as the diſtance from C, C, (the main breaching-batteries,) to F muſt render the latter rather inſecure, and expoſe it both to the batteries of the place, and to the ſallies of the garriſon: it is therefore given merely as an illuſtration of the terms uſed in the explanation of all that relates to enfilade. When ſhipping, or craft of any deſcription, lie behind a mole, ſo as to be ſecure from the direct fire of any battery, the ricoçhet-enfilade may be adopted, either by elevation, as ſhewn above; or by depreſſion, as from the cannon at P directed downwards to Q; whence the ſhots will bound over the mole R, and fall among the veſſels behind it. This is occaſionally done to deſtroy veſſels in a harbour, or to enfilade ſuch as may be actively employed in any attack; and thus to force them to a change of poſition, rather than ſuffer themſelves to be raked fore and aft with hot balls.

ENFILED, in *Heraldry*, is applied to a ſword, on which is placed the head of a man or beaſt, or any other charge.

ENFRANCHISEMENT, the incorporating any man into a ſociety or body politic. See Freedom and Franchise.

Thus, he that by charter is made denizen of England, is ſaid to be enfranchiſed. The like is underſtood of a perſon made a citizen of London, or other city or corporate town; becauſe he is thereby made partaker of the liberties appertaining to the corporation whereof he is enfranchiſed.

EN FRAPPANT, *Fr.*, in *Muſic*, a term applied, in beating time, to the firſt note of a bar.

ENGADINE, in *Geography*, one of the higheſt vallies of Switzerland, in the canton of the Griſons. It is divided into the Upper and Lower Engadine. St. Martin's bridge on the river Inn ſeparates the Lower Engadine from the Tyrol. The towns of this valley are leſs agreeable than thoſe of the upper one; but the ſoil is uncommonly productive. In ſome places the roads are narrow and rocky, and nature diſplays its wildeſt ſcenes. The river Inn is often compreſſed in a narrow deep channel: there are, however, a few fine plains, where fruits come ſooner to maturity than in the Upper Engadine, from which it is divided by the Pont Alta. The ſituation of the upper valley is much higher; it has very long winters, and the air is generally cold. In the midſt of ſummer, night froſts nip the corn and fruits. The towns are agreeably ſituated, and moſtly handſome, built of free-ſtone, and painted white; even the barns are fine buildings. The river Inn flows ſlowly in a larger bed; there are ſeveral beautiful bridges of a ſingle arch thrown over it. Near the pretty town of Schoulz are fourteen ſprings of mineral water of different qualities. There are ſeveral manufactures, chiefly iron works and founderies, in the Engadine, which give employment to a great number of its inhabitants, and an appearance of chearfulneſs and comfort to their habitations.

ENGAGE, *To*, when applied to *Military* or *Naval Affairs*, means to attack. Perhaps no circumſtance incident to warfare requires more precaution, or indeed more judgment, than that relating to the giving battle to an enemy. The general, or commander of any deſcription, who neglects to provide againſt thoſe checks which ariſe, often when leaſt expected, or for following up any advantage he may gain, eſpecially if it be within the limits of his anticipations, muſt be totally unqualified for ſo reſponſible and ſo important a ſituation. We ſpeak principally of proceedings in the field, where many alterations and much diverſity may be perpetually offering; for we conſider the manner in which battles on the ocean generally proceed, and in which they almoſt invariably terminate, to be ſo pre-eminent as to leave us only the opportunity of deſcribing them, (as we ſhall do under the head of ENGAGEMENT,) and to debar us, unleſs indeed we wiſhed to incur the charge of preſumption, from ſtating when or how ſingle ſhips or fleets ſhould engage the enemy.

In the firſt inſtance, it will be abſolutely neceſſary for the commander of an army to know, with preciſion, the ſtates of health, of diſcipline, of fatigue, of ſupply, and of competency in general, of every corps compoſing his army. He muſt be thoroughly informed as to the condition and numbers of his cattle, of the amount of his proviſions, and of the manner in which the ſeveral corps, the cattle, and the ſupplies, are diſtributed along his line. He muſt have a thorough knowledge of the numbers, the diſpoſition, the ſupplies, and the probable reſources, of the forces oppoſed to him; as well as of the nature of their warfare, their general habits, the ſtrong poſts in their rear, the opportunities they may have of forming ambuſcades, or of retreating to advantage; and eſpecially whether, in caſe of ſucceſs, he may be able to avail himſelf of thoſe invaluable opportunities which the valour and diſcipline of his troops may offer to his acceptance.

However confident a general may be of ſucceſs, he muſt never loſe ſight of the poſſibility of a reverſe: in truth, it is moſt generally found, that where the beſt preparations are made againſt diſaſter, the moſt decided victories are obtained. This is natural, both becauſe the whole of a line feel inſpirited by the reflection, that due proviſion is made for the worſt; and becauſe, where ſuch arrangements are carefully preconcerted, the appropriate remedy is prompt for application, and the enemy are rendered unable to continue in that line of ſucceſſes, which, but for ſuch apt oppoſition to their momentary or local advantages, muſt inevitably be at their command.

Whenever we obſerve that a commander courts the opinions of thoſe whoſe rank and experience may qualify them to offer advice, we may conſider it a moſt fortunate omen. The immortal Nelſon always diſcloſed his plans, and opened his mind fully, to the admirals and captains under his command: he ſolicited the correction of whatever errors might have crept into his projects, and was eagerly anxious that all ſhould have a competent underſtanding of his intentions. This ought ever to be the ſtudy of a commander; elſe, ſhould he fall, or ſhould unforeſeen accidents occur in any part of his line, his ſucceſſor, as well as his ſubordinates, muſt be totally at a loſs either to continue victorious, or to arreſt the progreſs of the enemy.

But perhaps the moſt eſſential point may be for a commander to aſcertain how far his troops are well diſpoſed to the cauſe; whether they proceed to engage with alacrity and zeal; and whether they have an entire confidence in the courage and abilities of their leaders. This part of the ſubject is ſometimes overlooked, until it is too late to be remedied; and the moment of engaging is the moment of treaſon, or of cowardice. It is true, the Britiſh army may claim an exemption from theſe ungovernable miſchiefs; but no commander ſhould be indifferent to matters which are within the ſcope of poſſibility, and which may often be avoided by a little courteſy, or by ſome well directed policy. We ſhould conſider, that in our time the moſt unforeſeen events are daily brought forth; that the opinions of perſons inimical to the welfare of the ſtate are every day promulgated; and that, within theſe very few years, even a field officer of our army endeavoured to miſlead thoſe guards, who are excluſively appointed to protect his majeſty's ſacred and moſt valuable life. Fortunately for Britain,

> “ Such divinity doth hedge our king,
> That Treaſon dared but peep at what it would!”

Therefore we may ever hope that the diſpoſition of our ſoldiery will remain unſhaken; and that we may find them, as they ever have been, bold, active, and obedient in the field, and ready on all occaſions to engage in ſupport of our king, and our conſtitution.

It may be proper to add, that too much ardour to engage may exiſt in an army: this is aſſuredly dangerous. There is a certain eſtabliſhed coolneſs in veteran regiments, reſulting from the preſence of perhaps only a ſmall portion of veterans among them, which is highly conducive to the character and to the proweſs of the corps at large. Such regiments are admirably calculated for reſiſtance; while new levies are generally more ſuited to the charge, and to thoſe tremendous conflicts which ſpeedily terminate the ſtruggle in their quarter. In truth, we are well aſſured from the moſt reſpectable authorities, as well as from the numerous facts which proudly and pre-eminently offer themſelves to our notice, that nothing can reſiſt the attack of our new regiments; while, on the other hand, nothing can ſubdue the firmneſs and patience of our old ones.

ENGAGEMENT, in the *Military Profeſſion*, relates to ſuch conflicts as take place between bodies of armed men, generally regular troops, and eſpecially to that kind of warfare which is carried on between armies of ſome magnitude, in contradiſtinction to thoſe leſs extenſive conteſts, which ordinarily are conſidered as ſkirmiſhes. Engagements may be either partial or general; in the latter caſe, they are commonly attended with marked and decided conſequences; whereas, in the former inſtance, little or no difference may be made in the poſitions of the contending powers. We generally find, that, according to the modern mode of warfare, great ingenuity and cunning are exerted, for the purpoſe of deceiving the adverſary into an opinion of a general attack. This is done with the intention of preventing reinforcements being ſent from any part, the whole being kept in action, while the main attack is made on ſome point, either naturally weak, or by gaining which the fortune of the day may be determined in favour of the aſſailants. This, although it bears the appearance of a general engagement, is in fact but a partial aſſault; the greater portion of the conteſt falling upon a few regiments, which, unleſs properly ſupported, are commonly ſwept away: to ſay the leaſt, they muſt ſuffer very conſiderably.

Previous to engaging the enemy, every attention muſt be paid to ſecuring a retreat, in caſe of a check. This precaution is indiſpenſable in all ordinary inſtances; though, in ſome ſituations, it may be found the beſt policy to deſtroy the means of evaſion, under the intention of convincing the army that it has only the alternatives of victory or death. Thus, when Cæſar landed in Britain, he deſtroyed the fleet which had brought him to our ſhores; a meaſure which, in thoſe times, compelled the invaders to fight to the laſt. They knew they had to contend with an enemy, from whom no quarter was to be expected; therefore, like rebels, they ſtruggled for life; they fought virtually with halters around their necks; and, thus rendered deſperate, contended with ſuch ſavage, ſuch unrelenting fury, as neceſſarily cauſed the engagement to be ſanguinary to an extreme.

Engagements are of two kinds; namely, either in the field, where the oppoſing parties are both diveſted of the protection of fortifications of any deſcription, ſuch as we ordinarily find to take place in open countries; the other conſiſting of that mixed kind of warfare, which compriſes the attack and defence of *abbaties*, the croſſing of rivers in the face of an enemy, and, on many occaſions, the attacks made upon open towns, &c. With reſpect to thoſe engagements which are connected with the ſtorming of lines, or of fortifications of any deſcription, we conſider ſuch to appertain to that protracted ſyſtem included under the head of *ſiege*, which ſee; and the attacks upon ſuch to be, not engagements, but aſſaults.

It is ſcarcely to be credited upon what very ſlight incidents the fate of an engagement may depend! Circumſtances, which, if conſidered in the cabinet, ſhould appear to be akin to impoſſibility, ariſe unexpectedly, and change the face of affairs inſtantaneouſly. Hence, during the moment of conteſt, a commander ſhould be intent on obviating thoſe miſchiefs which muſt reſult from the falling back, or the failure, of any part of his army. He muſt carry in mind, and perhaps might advantageouſly delineate on a card, the great outline of the engagement; ſtudying to chooſe ſuch a poſition as may give him a general view of the field, but moſt eſpecially of ſuch portions as may either appear to him either weak, *ab origine*, or to be hard preſſed by the enemy.

To deſcribe an engagement is next to impoſſible; for though we might perhaps afford ſome general idea of the incidents uſually occurring during a battle, ſuch is the diverſity to be found in the localities, as well as in the ſyſtems of warfare adopted even by perſons in the ſame ſervice, that to enter upon the inveſtigation of the ſubject in all its bearings, and throughout its amplifications, would be to compriſe a volume of no ſmall magnitude. We muſt, therefore, content ourſelves with obſerving, that the ordinary diſpoſition for an engagement, where no particular *point d'appui* is in queſtion, conſiſts of two or more lines, compoſed chiefly of infantry, properly ſupported by artillery of various natures, that is to ſay, of braſs 18 pounders, alſo of 12, 9, 6, and 3 pounders, with a portion of howitzers, commonly of $4\frac{1}{2}$, or $5\frac{3}{4}$ inches diameter in the bore, or eventually up to 8 inches. Theſe are placed in the intervals between the ſeveral regiments, while one or more parks of artillery are arranged in ſuch parts of the ſeveral lines, as may appear to require that powerful aid; or on ſuch commanding ſpots as may enable the artilleriſts to act with greater effect againſt the enemy. See TACTICS, *Military*.

Where the ground may admit, the cavalry often commences the action, by endeavouring to prevent the enemy from forming upon, or taking poſſeſſion of, ſtrong poſitions. The horſe artillery, together with the pieces of lighter conſtruction which can be ſpeedily withdrawn, advance to cannonade; while the infantry may be deploying from column into line, or forming according to the inſtructions of the generals commanding in the ſeveral quarters of the army; to whom the commander in chief previouſly communicates his intentions. During this time, the greateſt order, coolneſs, and promptneſs, are indiſpenſably neceſſary: it is now that ſuperior diſcipline will manifeſt itſelf, and that the real powers of an army will be aſcertained. Let it not, however, be ſuppoſed, that that kind of ſymmetrical order which is the boaſt of our parade martinets, is to be found in the field of battle! Far otherwiſe; in lieu of regular firings by diviſions, each individual loads and diſcharges his piece when, and how he can; in place of a regulated pace conforming to any particular cadence, the advances and retreats are generally too much diveſted of that order, and of that ſyſtematic uniformity, which ſo highly delight the fair ſex when they viſit our ſummer camps, to witneſs the ſplendid array attendant upon parade evolutions. In ſhort, the celebrated ſong in the "Recruiting Serjeant" is the beſt, and moſt pithy deſcription of an engagement we have ever heard, eſpecially that part which relates to the moſt arduous portions of the conteſt.

"But the merrieſt joke of all,
Is when to cloſe attack we fall.
Killing, wounding, maiming, butting,
Daſhing, flaſhing, ſlaying, cutting:
Horſe and foot,
Both go to't;
Blood and thunder!
Then to plunder,
Oh! what a charming thing's a battle!"

A very charming thing, indeed; eſpecially when we conſider that many of the wounded are often murdered by perſons, chiefly women, who follow the ſeveral armies, for the purpoſe of plundering ſuch unfortunate brave men as may be incapable of making reſiſtance. It is, indeed, a well-known fact, that this iniquitous and diſgraceful practice, is more than ever prevalent in many countries, whoſe inhabitants, being at leaſt on a par with thoſe of the moſt enlightened parts of the world, ſhould rather endeavour to ſoften the rigours of war, than to perpetrate the moſt ſavage cruelties on thoſe whoſe misfortune it may be to be diſabled in the courſe of an engagement.

Theſe fluctuations between victory and defeat, which ſometimes alternate for hours together between contending armies, muſt afford the moſt lively intereſt to a ſpectator, and cannot fail to produce the moſt exquiſite ſenſations of joy, or of miſery, in the breaſts of the reſpective commanders. What can afford a greater gratification than the complete ſucceſs of an army? or what can occaſion more pointed chagrin than the evidence of its defeat? Perhaps, of all the men who ever experienced ſuch reverſes, the old king of Pruſſia may be conſidered as the moſt illuſtrious inſtance of fortitude under diſaſter, and of moderation when ſucceſsful. Theſe good qualities, though they may have been coeval with his birth, muſt neceſſarily have been conſiderably enhanced, by that intenſe application the monarch paid to the diſcipline of his army. Hence, we are informed, that no reverſe appeared to him irremediable, and that no victory was conſidered by him to be permanent. Such a man muſt have viewed an engagement under very peculiar impreſſions: he muſt have been moſt ardently intent upon the conſideration of what evolutions would be moſt ſuited to the events paſſing under his notice; while at the ſame moment, his mind muſt have been actively employed in the conſideration of reſources, wherewith he might, according to the modern cant term, "carry on the war." We muſt, however, remark, that the great Frederick rarely had a large army; but that which he had, though comparatively ſmall, was of immenſe ſtrength: every part was ſyſtematically organized under the moſt ſevere code of diſcipline, and under the moſt penetrating obſervation. We have heard old officers ſtate, that the Pruſſian army, under their immortal royal general, performed its evolutions, and preſerved the ſame order, and went through their firings, as regularly while in action as when on their ſeveral parades. We fear this ſingular inſtance of military conſiſtency, is not likely to be again diſplayed by the Pruſſian army at this date; nor, indeed, have we any authority, if paſt events are to guide us, for expecting to ſee, or hear, that they ſhould throughout an engagement diſplay thoſe qualities which, however much we may commiſerate the ſufferings of thoſe individuals whereof it was compoſed, characterized the military eſtabliſhment of that now ill-fated country! We leave to our readers to contemplate what muſt be the feelings of the brave marſhal Mollendorff, who, we believe, is the only ſurviving general now of the many that held commands under that military prince, whoſe exiſtence in theſe times would, no doubt, have given a very different aſpect to the affairs of Europe.

Engagement, in a *Naval Senſe*, denotes a particular or general battle at ſea, or an action of hoſtility between ſingle ſhips, or detachments, or ſquadrons of men of war: the whole economy of which may be arranged under the heads of preparation, action, and repair. The preparation is begun by iſſuing the order to clear the ſhip for action, which is repeated by the boatſwain and his mates at all the hatchways. The hammocks are firſt removed; every ſailor ſtowing his own bedding properly and firmly cording it with a laſhing, or line provided for that purpoſe: as each ſide of the quarter deck and poop is furniſhed with a double network, ſupported by iron cranes fixed immediately above the gunnel or top of the ſhip's ſide; the hammocks, thus corded, are firmly ſtowed by the quarter-maſter between the two parts of the netting, ſo as to form an excellent barrier or ſort of parapet, to prevent the execution of ſmall ſhot on the quarter-deck: the tops, waiſte, and fore-caſtle, are fenced in the ſame manner.

At this time all heavy luggage, ſuch as cheſts, &c. are handed down into the hold, and the ſurgeon, with his mates and aſſiſtants, together with whatever women may be on board, deſcend into a part called the cock-pit; which, being below the level of the water, is conſidered to be tolerably ſecure; various inſtances have, however, been known of ſhots, between wind and water, finding their way to that retirement.

At the ſame time the boatſwain and his mates are employed in ſecuring the ſail-yards, to prevent them from tumbling down when the ſhip is cannonaded, whereby it might be diſabled. The yards are ſecured by ſtrong chains or ropes, beſides thoſe by which they are uſually ſuſpended. The boatſwain alſo provides the neceſſary materials for repairing the rigging; and the carpenter and his crew prepare ſhot-plugs and mauls to cloſe up any breach that may be made near the ſurface of the water, and provide their ironworks neceſſary to refit the chain-pumps. The gunner, with his mates and quarter-gunners, examine the cannon of the different batteries, and provide proper charges, &c. The maſter and his mates attend to the number and trimming of the ſails, &c. The lieutenants viſit the different decks, taking care that all incumbrances are removed, and giving inſtructions to the other officers, that every thing may be ready for the expected engagement at a moment's warning. When the hoſtile ſhips have approached each other to a competent diſtance, the drums beat to arms: the boatſwain and his mates pipe "all hands to quarters!" at every hatch-way. The perſons appointed to manage the great guns immediately repair to their reſpective ſtations; crows, hand-ſpikes, rammers, ſpunges, powder-horns, matches, and train-tackles are placed in order by the ſide of every cannon. The hatches are laid to prevent any one from eſcaping into the lower apartments. The marines are drawn up in rank and file, on the quarter-deck, poop, and forecaſtle. The laſhings of the great guns are let looſe, and the tompions withdrawn: the whole artillery, above and below, is run out at the ports, and levelled to the point-blank range ready for firing. When the neceſſary preparations are finiſhed, the commencement of the action is determined by the mutual diſtance and ſituation of the adverſe ſhips, or by the ſignal from the commander in chief of the fleet or ſquadron. The cannon being levelled in parallel rows, projecting from the ſhip's ſide, the moſt natural order of battle is evidently to range the ſhips a-breaſt of each other, eſpecially if the engagement is general. The moſt convenient diſtance is probably within the point-blank range of a muſket, ſo that all the artillery may do effectual execution. The combat uſually begins by a vigorous cannonade, accompanied with the united efforts of all the ſwivel-guns and ſmall arms. Inſtead of firing platoons, or vollies of cannon at once, the general rule throughout the ſhip on theſe occaſions is to load, ſpunge, and fire the guns with all poſſible expedition, yet without confuſion or precipitation. The captain of each gun is enjoined to fire only when the piece is properly directed to its object. The lieutenants who command the different batteries traverſe the deck, to ſee that the battle is proſecuted with vigour, and to animate the men in their duty. The midſhipmen ſecond theſe injunctions, and give aſſiſtance where it is required at the guns committed to their charge. The gunner takes care that the artillery is ſupplied with powder, and that the cartridges are conveyed along the decks in covered boxes.

During the action, the captain manœuvres his ſhip to the beſt advantage; cauſing the maſter ſo to lay her on the enemies' bows, or quarters, and eſpecially under her ſtern, as may give thoſe favourable reſults attendant upon a ſafe, but annoying, poſition. Should any intervals ariſe, owing to the ſituations of the ſeveral ſhips, it is employed in clearing the decks, in repairing the damaged rigging, and in providing for a renewal of the engagement. If, as very often happens, the enemy make ſail with the view to eſcape, the guns are ſecured, while all hands turn to for the purpoſe of giving chaſe: in this inſtance, the great object is to come up with the flying foe; therefore all theſe ſails which were furled or clued up, with the intention of either having leſs to manage, or to keep them free from danger, are now ſpread to the gale, and every effort is made to regain a poſition within ſuch a diſtance as may cauſe the enemy to ſtrike his flag, and to ſurrender. Should he ſtill perſiſt, the engagement muſt continue, until, being a complete wreck, he may conſider further oppoſition uſeleſs. So ſoon as he has ſtruck, his ſhip is taken poſſeſſion of by a detachment from the victor's crew, and the whole of the ſubdued party are put under hatches in the hold, or, if neceſſary, are otherwiſe ſecured in the bilboes, &c. while a prize maſter, generally a lieutenant, is put on board, for the purpoſe of navigating the prize, according to ſuch orders as he may receive.

It ſometimes happens, that, where an enemy is very determined, it is neceſſary to board; indeed, this not unfrequently occurs, owing to veſſels adventitiouſly coming in contact. Previous to the adoption of this deſperate meaſure, it will be abſolutely neceſſary to conſider well how far it may be likely to ſucceed. If the oppoſing crew be numerous, and eſpecially if abounding in marines, or if there be any number of military on board, much management, activity, and reſolution will be required to carry the point; which is generally effected by laying along the lee waiſt or quarter, or perhaps upon the bow, and, after having grappled, by means of chains, or of ſmall boarding grapnails ſuſpended by chains from the yards, to lower down the boarding platforms, (if there be any,) and thus to ruſh upon the enemy's deck. In ſome inſtances, ſhips have been boarded by entering at the ports, ſtern, or quarter gallery, &c. either of which modes will often ſucceed, where the whole of the oppoſing crew ruſh with too much precipitation, to the upper works, with the intention of reſiſting thoſe who are about to board upon the deck. The bowſprit is frequently reſorted to, as the means of entering an enemy's ſhip: this, being laid over the ſtem, or tafrail, will generally enable the boarders to proceed with ſufficient facility, while the marines are employed in keeping up a ſharp fire, to drive the defenders off the poop. It is, however, a very hazardous concern, and chiefly reſorted to on deſperate occaſions, by privateers, or where, though ſtrong in point of crew, a veſſel may not be of ſufficient force to lie alongſide her opponent. A repulſe in boarding is peculiarly dangerous, and very commonly leads to defeat. It almoſt invariably happens, that, on ſuch occaſions, great numbers of the boarders are deſtroyed; whereby the reſidue of the ſhip's company are conſiderably diſpirited; at leaſt, this is an ordinary reſult among foreigners; Britiſh tars are not ſo eaſily daunted, but may be again, and again, led to the attack.

When the engagement is concluded, they begin the repair. The cannon are ſecured by their breachings and tackles; the ſails that have been rendered unſerviceable, are unbent; and the wounded maſts and yards ſtruck upon the deck, and fiſhed or replaced by others. The ſtanding rigging is knotted, and the running rigging ſpliced wherever this is neceſſary. Proper ſails are bent in the room of thoſe that are become uſeleſs. The carpenter and his crew repair breaches in the ſhip's hull by ſhot-plugs, pieces of plank, and ſheet-lead. The gunner and his aſſiſtants repleniſh the allotted number of charged cartridges, and refit the damaged furniture of the cannon.

When two fleets or ſquadrons are preparing for engagement, it will be the endeavour of the admiral or commander in chief to come to action as ſoon as poſſible. To facilitate the execution of the admiral's orders, the whole fleet is ranged into three ſquadrons; each of which is claſſed into three diviſions, under the command of different officers. Before the action begins, the adverſe fleets are commonly drawn up in two lines parallel to each other, and cloſe-hauled. When the admiral diſplays the ſignal for the line of battle, the ſeveral diviſions ſeparate from the colours in which they were diſpoſed according to the uſual order of ſailing, and every ſhip crowds into its ſtation in the wake of the next a-head, at the diſtance generally of about fifty fathom; which diſtance is regularly obſerved from the van to the rear: though the admiral may ſometimes find it neceſſary to contract or extend his line, according to the length of that of his adverſary; always taking care that his own line be ſecure from being doubled, which might throw his van and rear into confuſion. When the reverſe fleets approach each other, the courſes are commonly hauled up in the brails, and the top-gallant ſails and ſtay-ſails, furled; the frigates, tenders, and fire-ſhips, being hauled upon the wind; lie at ſome diſtance behind the line of battle; and tranſports and ſtore ſhips lie beyond theſe, at a ſtill greater diſtance from the ſcene of action; and if the number of ſhips allows it, a body of reſerve from the different ſquadrons is ſelected to cover the fire-ſhips, &c. and ſtationed oppoſite to the weakeſt parts of the line, ſo that they may readily fall into the line in caſe of neceſſity. Each ſhip forming the line ſhould keep cloſe to its ſtation during the engagement; the aſſault of boarding being ſeldom permitted unleſs in ſingle action: becauſe the regularity of a cloſe line conſtitutes the principal force of the fleet; and the ſkill of the admiral is greatly concerned in keeping his line, notwithſtanding unequal attacks and damage, as complete as poſſible. If he proves victorious, he ſhould proſecute his victory as much as poſſible, by ſeizing, burning, or deſtroying the enemies' ſhips. If he is defeated and reduced to the neceſſity of retreating, he may judge it expedient, for greater ſecurity, to range his fleet into the form of a half-moon, placing himſelf in the centre. The enemies' ſhips that attempt to fall upon his rear will thus be expoſed to the fire of the admiral and his ſeconds, and the eſcape of his own ſhips will be facilitated, whilſt the purſuit of his averſary is retarded. Upon the whole, the real force of ſuperiority of a fleet, conſiſts leſs in the number of veſſels and the vivacity of the action, than in good order, dexterity in working the ſhips, preſence of mind, and ſkilful conduct in the admiral and captains. Falconer's Marine Dict. art. *Engagement*.

There formerly exiſted certain ſuppoſed axioms, in regard to the ſeveral modes of forming in line of battle a-head, or a-breaſt; and much attention was paid to the weather-gage, as well as to other ſuch matters: fleets uſed then to manœuvre for ſeveral days, obviouſly intent upon gaining ſome particular poſition, which was ſuppoſed to be indiſpenſably neceſſary towards a ſucceſsful iſſue. Of late years this has been totally, or at leaſt very generally neglected; for in lieu of fleets, or ſingle ſhips, now dancing minuets for ſuch a purpoſe, we ſee them ranging up with little ceremony, and intent only on getting into action; whatever may be the ſtate of the wind or of the weather. All that a Britiſh commander requires of his maſter, nowadays, is, "Lay me alongſide the enemy;" a few guns more or leſs, or even an extra deck, on the part of the enemy, being diſregarded. It is to this ſpirit, that our ſhores are indebted for ſafety, and our commerce to that wide range afforded by the univerſal command which Britain holds over the ocean. It is with the utmoſt pride and ſatisfaction, we witneſs the glorious exertions of our invincible tars: for ſuch we may fairly deſignate men who, regardleſs of every danger, and urged by the moſt patriotic zeal, bear away the palm when, and wherever the enemy, however ſuperior in guns, or in numbers, give them the opportunity of diſplaying that valour which, though uncontroulable in oppoſing a foe, is rapidly metamorphoſed into humanity, ſo ſoon as the victory may be proclaimed, or that the voice of diſtreſs may be heard! Surely we never can ſufficiently reward thoſe heroes who, as Hudibras ſays, ſtand forward—

> "To fight our battles in our ſteads,
> And have their brains beat out o' their heads;
> Encounter in deſpite of nature,
> And fight at once with fire and water,
> With pirates, rocks, and ſtorms, and ſeas."

A naval engagement is a branch of warfare in which the Britiſh character appears to the utmoſt advantage, and in which we ſtand confeſſedly pre-eminent over the whole univerſe. We derive the more ſatisfaction, from the reflection, that our credit and proweſs are not ephemeral, nor dependant upon any temporary weakneſs on the part of our opponents: we contemplate them as heir-looms, bequeathed to us from a noble and brave anceſtry, whoſe examples have been duly followed, and whoſe reputation has, no doubt, contributed to that zeal, and to that emulation, which pervade every part of the Britiſh navy, and induce our tars to perſevere in their ſtruggles for the preſervation of our rights and liberties as a people; while, at the ſame time, each individual aims to uphold his own character for bravery, ſubordination, and generoſity. See Battle, Boarding, *Line of Battle*, and Signal.

Engagement, in *Engliſh Hiſtory*, was the obligation impoſed by Oliver Cromwell required to be ſigned by every member of the Firſt Parliament in 1654, aſſembled by his authority, after he was declared Protector, *viz.* "I *A. B.* do hereby freely promiſe and engage myſelf to be true and faithful to the Lord Protector, and to the commonwealth of England, Scotland, and Ireland, and ſhall not (according to the tenure of the indenture whereby I am returned to ſerve in this preſent parliament) propoſe or give any conſent to alter the government, as it is ſettled in one ſingle perſon and a parliament." Many, who refuſed to ſign this engagement, were excluded from the houſe.

ENGALLA, in *Zoology*, the Ethiopian hog or African wild boar. See Sus *Æthiopicus.*

ENGALLIM, in *Ancient Geography*, a town of Judea, in the tribe of Benjamin, ſituated on the coaſt of the Dead ſea, where, according to St. Jerom, the river Jordan diſcharged itſelf into that ſea.

ENGAMOS, in *Natural Hiſtory*, the name given by the people of ſome parts of Guinea to a root very common there, and much reſembling our larger ſort of turnips, but not ſo ſweet or juicy. They commonly boil theſe with their battatas, in the ſame kettle with their meat. The latter of theſe roots, which is conſiderably different from our potatoe, gives a fine flavour to the whole, and makes the broth and meat taſte as if roſe-water were added to it. The engamos alſo partakes of the flavour, and in this caſe becomes very agreeable. Phil. Tranſ. N° 108.

ENGANNIM, in *Ancient Geography*, a city in the plain belonging to Judah, Joſh. xv. 34.—Alſo, a city of Iſſachar; given to the Levites of Gerſhon's family. Joſh. xix. 21. xx. 29.

ENGANNO, or Deceit *Iſland*, in *Geography*, an iſland in the Eaſtern ſea, at a ſmall diſtance from the S.W. coaſt of the iſland of Sumatra. S. lat. 5 9′. E. long. 102° 44′.

Ships that paſs the ſtraits of Sunda, in the weſterly monſoon, generally run in ſight of Enganno. This iſland is 6 or 7 leagues in length, and not quite half as broad. It is not high, and can only be diſcerned at the diſtance of 5 leagues. It is covered with trees, and always appears green. For a more particular account of this iſland, ſee Phil. Tranſ. for 1778.

ENGANO, Cape, a cape on the eaſt coaſt of the iſland of St. Domingo. N. lat. 18° 27′. W. long. 68° 52′.

Engano, or Enganno, *Cape*, the N.E. point of the iſland of Luçon, in the Eaſt Indian ſea. N. lat. 17 45′. E. long. 121° 20′.

ENGASTRIMANTES, Εγγαστριμαντεις, in *Antiquity*, called alſo *Engaſtrimythi*, Εγγαστριμυθοι, a deſignation given to ſuch diviners as were poſſeſſed with dæmons, which either lodged or ſpoke within their bodies. Pott. Archæol. Græc. lib. ii. cap. 12. tom. i. p. 301.

ENGASTRIMYTHUS, Εγγαστριμυθος, or *Engaſtrimander*, a perſon who ſpeaks from, or with the belly, without opening his mouth; or, if open, without ſtirring the lips.

Thus called by the Greeks, from εν, γαστηρ, *belly*, and μυθος, *ſpeech*; and by the Latins, *ventriloquus*, *quaſi ex ventre loquens.*

The ancient philoſophers, &c. are divided on the ſubject of the engaſtrimythi: Hippocrates mentions it as a diſeaſe. Others will have it a kind of divination, and aſcribe the origin and firſt diſcipline thereof to one Eurycles, whom nobody knows any thing of. Others attribute it to the operation or poſſeſſion of an evil ſpirit; and others, to art and mechaniſm.

The moſt eminent engaſtrimythi were the Pythians or prieſteſſes of Apollo, who delivered oracles from within, without any action of the mouth or lips.

St. Chryſoſtom and Oecumenius make expreſs mention of a ſort of divine men, called by the Greeks engaſtrimandri, whoſe prophetic bellies pronounced oracles.

M. Schottus, library-keeper to the king of Pruſſia, in a Diſſertation on the Apotheoſis of Homer, maintained that the engaſtrimythi of the ancients were only poets; who, when the prieſteſs could not ſpeak in verſe, ſupplied the defect, by explaining or delivering in verſe what Apollo dictated in the cavity of the baſon, placed on the ſacred tripod.

Leo Allatius has an expreſs treatiſe on the engaſtrimythi. See Ventri-loquists.

ENGEDI, in *Ancient Geography*, *q. d.* the fountain of the goat, called alſo *Hazazon-Tamar*, or the palm-tree city, from the great quantity of palm-trees that ſurrounded it, a city of Paleſtine, in the tribe of Judah (Joſh. xv. 62.), ſituated near the lake of Sodom, 300 furlongs from Jeruſalem, not far from Jericho, and the mouth of the river Jordan. It was in a cave of the wilderneſs of Engedi, that David had an opportunity of killing Saul, and of ſparing his life, then in purſuit of him. 1 Sam. xxiv. 1, 2, 3, &c.

ENGEL. See Anglen and Angles.

ENGELACH, in *Geography*, a town of Germany, in the circle of Lower Saxony, and biſhopric of Hildeſheim; 15 miles S.W. of Alfeld.

ENGELBERG, an extenſive narrow valley of Switzerland, in the canton of Underwalden; its length exceeds twelve miles, and it is hardly ſix miles broad. It was formerly called the Hahnenberg (Cocks' mountain), but when the abbey church was conſecrated, ſome inhabitants pretended they had heard the melodious concerts of the angels in heaven, which made them call it *Engelberg*, (the Angels' mountain). The inhabitants are numerous and remarkable for the innocence of their manners, and for their hoſpitality to ſtrangers.

The abbey of Engelberg is 9 miles S.W. of Altorf. It was founded in the year 1125.

ENGELBRECHTS, a town of Germany, in the archduchy of Auſtria; 95 miles N.N.W. of Bavarian Waidhoven.

ENGELHARTZEL, a town of Germany, in the archduchy of Auſtria; 9 miles E. of Paſſau.

ENGELHAUS, a town of Bohemia, in the circle of Saatz; 2 miles E.S.E. of Carlſbad.

ENGELHOLM, a town of Sweden, in the province of Schonen, or Scania, ſituated at the mouth of a river which runs into the Cattegat, 12 miles from Helſingborg. It is the twentieth town in rank among thoſe which vote in the Swediſh diet. Its name is ſaid to be derived from the Angles, who either firſt came from this neighbourhood, or paſſed over to it from Denmark, and built the place for the conveniency of trade. The latter conjecture is the moſt probable.

ENGELSBERG, a town of Sileſia, in the principality of Appau; 5 miles N.N.W. of Freudenthal.

ENGELSBURG, a ſmall town of Pruſſia, in the diſtrict of Culm, with an ancient caſtle not far from Graudentz.

ENGELSDORF, a town of Bohemia, in the circle of Boleſlaw; 10 miles N.N.E. of Krottau.

ENGELSTEIN, a town of Pruſſia, in the province of Natangen; 48 miles S.E. of Konigſberg.

ENGELSTETTEN, a town of Germany, in the archduchy of Auſtria; 23 miles E. of Vienna.

ENGEN, a town of Germany, in the circle of Swabia, and principality of Stuhlingen: 12 miles N.N.E. of Schaffhauſen, and 20 N.N.W. of Conſtance.

ENGENDERING, or Ingendering, the act of begetting or producing the kind, by way of generation.

The term is likewiſe applied to other productions of nature: thus, meteors are ſaid to be engendered in the middle region of the air. Crude fruits engender worms. The ancients believed, that inſects were engendered of putrefaction.

ENGENTHAL, in *Geography*, a town of Germany, in the circle of Franconia; 13 miles E. of Nuremberg.

ENGER, a town of Germany, in the kingdom of Weſtphalia, and county of Ravenſburg; 3 miles W. of Hervorden.

Enger *Sea*, a lake of Carinthia, 10 miles N.N.W. of Feltkirchen.

ENGERSTORFF, a town of Germany, in the archduchy of Auſtria; 10 miles S.W. of Ziſterſdorf.

ENGETAL, a valley of Switzerland, in the canton of Baſle, remarkable for its abbey, which was ſecularized in 1534, and where a bible was printed at the end of the fifteenth century, with N. Lyra's notes.

ENGGISTEIN, a ſmall town of Switzerland, one mile from Worbe, remarkable for its mineral ſprings, on whoſe account it is much viſited in the ſummer ſeaſon. The water contains a little copper. The accommodations of the place are very good.

ENGHELBRECHT, Cornelius, in *Biography*, a painter, born at Leyden in 1468. Having imitated the works of John Van Eyck, at Bruges, he returned to his own country, and had the honour of being the firſt who taught the Dutch to paint in oil; in which he wrought with very great reputation in his time, as well as in diſtemper; and was then accounted among thoſe moſt deſerving of eſtimation.

He was not quite ſo dry or formal in his manner of deſign as the painters of that period; and he caſt his draperies with more care, and better ſtyle, than they. His moſt admired performance is the repreſentation of the "Lamb" in the Revelation, which he painted for a chapel in the church of St. Peter at Leyden. The compoſition conſiſts of an immenſe crowd of figures, angels, martyrs, doctors, and fathers of the church, &c. and all the "holy hierarchy of heaven," combined together with an immenſe multitude of perſons of all nations. This picture is very ingenious in the painting of the various parts, but it muſt owe its reputation more to the lack of knowledge of the better qualities of art at the time it was painted, than to its own intrinſic worth. This artiſt died in 1533, at 65.

ENGHIEN, or Enguien, in *Geography*, a ſmall town of France, in the department of Jemmappe, chief place of a canton, in the diſtrict of Mons, with a population of 3045 individuals. It is 18 miles S.W. of Bruſſels, and 15 N. of Mons. N. lat. 50° 40′.

The canton contains 10 communes, and 13,674 inhabitants, on a territorial extent of 140 kiliometres. It is from this place that the eldeſt ſons of the princes of Condé in France, the laſt of whom was ſo baſely murdered by the orders of the French emperor Napoleon, derived the title of duke.

ENGIA, an iſland near the coaſt of the Morea, anciently called *Ægina*, which ſee. Engia gives name to a gulf on the S.E. coaſt of European Turkey, formerly denominated *Sinus Saronicus*. See Ægina.

ENGINE, in *Mechanics*, a compound machine, conſiſting of ſeveral ſimple ones, as wheels, ſcrews, levers, or the like, combined together, in order to lift, caſt, or ſuſtain a weight, or produce ſome other conſiderable effect, ſo as to ſave either time or force.

The word is formed of the French *engine;* of the Latin *ingenium*, wit; becauſe of the ingenuity required in the contrivance of engines, to augment the effect of moving powers.

The kinds of engines are innumerable; ſome for war, as the baliſta, catapulta, ſcorpio, aries, &c. others for the arts of peace, as mills, cranes, preſſes, clocks, watches; engines to drive piles, to bore cannon and water-pipes, (ſee Boring), to raiſe water, wheel and water-works; to extinguiſh fire, ſee Fire-*engine*, &c. See Hydrocanisterium. See Steam-*engine*, &c. See alſo Instrument.

Engine *for cutting Wheels*. See Cutting-*Engine*.

Engine *for cutting Fuſees*. See Fusee-*Engine*.

Engine *for ornamenting a Watch-caſe*. See Rows-*Engine*, or Rose-*Engine*.

Engine *for dividing Circles*, *Quadrants*, *Sextants*, and *Octants*. It is not our intention in this place to enter into the hiſtory of the different methods of dividing aſtronomical inſtruments into degrees and their ſub-diviſions, as ſucceſſively practiſed by Tycho Brahe, Hevelius, Dr. Hook, Mr. Abraham Sharp, Olaus Roemer, Mr. Graham, Mr. Jon. Siſſon, Mr. Bird, Mr. Ramſden, and Mr. Troughton, without the aid of an engine; but, as we propoſe to treat the ſubject at ſome length under our article Graduation *of Aſtronomical Inſtruments*, we beg leave to refer the reader to that head for ſuch particulars as relate to the manual operations performed by the beam-compaſs and otherwiſe, which are neceſſary for graduating all circles and other inſtruments, that are too large to be graduated by an engine.

Among all the improvements in chronometers and nautical inſtruments, that owed their origin, during the laſt century, to the munificent encouragement of the honourable Board of Longitude, there is none that has ſo much contributed to the intereſt of navigation, conſidered as a ſcience, as the engine at preſent to be deſcribed; the facility, and at the ſame time the accuracy, with which the meaſuring portion of any nautical inſtrument, however portable, can now be divided by our beſt engines, are truly aſtoniſhing; the fine dividing-ſtrokes, which, in many inſtances, are ſcarcely viſible to, and not legible by the naked eye, when magnified by a ſuitable lens, are perceived to be laid down with ſuch perfect equality, as to relative diſtances, that no one who has not examined the means by which they were effected, can conceive the poſſibility that the expedition, with which the diviſions are made, is equal to the accuracy with which they are meaſured and marked down. In Mr. Smeaton's paper, read to the Royal Society of London, on Nov. 17, 1785, on the "Graduation of Aſtronomical Inſtruments," he mentions an engine, made by Mr. Henry Hindley of York, which indented the edge of any circle in ſuch a way, that a ſcrew with fifteen threads acting at once, would, by means of a micrometer, read off any given number of diviſions, ſo as to anſwer the purpoſe of ſub-dividing the circle. It does not, however, appear that this engine, though it divided the circles of Hindley's equatorial inſtruments, was intended or adapted ſo much for graduating circles as for cutting the teeth of wheels in clock-work. (See Cutting-*Engine*.) The year in which it was ſeen by Mr. Smeaton was 1741, and, conſequently, was in Graham's time, who died in 1751. According to the ſame author, Mr. Ramſden, in conſequence of the reward offered by the Board of Longitude to Mr. Bird, for his method of dividing, in the year 1760, turned his thoughts towards the contrivance of an engine that would divide nautical inſtruments with ſufficient accuracy, without the tediouſneſs of manipulation. Accordingly, conſidering the nature and properties of the endleſs ſcrew, and probably contemplating what Hindley had previouſly done in this way, he completed an engine with an indented plate, or wheel, of thirty inches diameter, which, though it did not completely anſwer his expectations to their full extent, yet was found very uſeful for dividing theodolites and ſuch common inſtruments with great facility. This was effected before the ſpring of 1768, and, in 1774, a much larger and better engine was produced, with an indented plate of 45 inches diameter, which divided a ſextant for Mr. Bird's examination ſo accurately, that the Board of Longitude, ever ready to remunerate any ſucceſsful endeavour to promote the lunar method of determining the longitude at ſea, did not heſitate to confer an handſome reward on the inventor, but on condition that the ſaid engine might be at the ſervice of the public, and that Mr. Ramſden would publiſh an explanation of his method of making and uſing it, which he accordingly did in a quarto pamphlet in the year 1777. The ſum of money given to Mr. Ramſden was 615*l.*, of which 300*l.* was conſidered as a reward for his improvement in the art of dividing inſtruments by means of his engine, and the remaining 315*l.* was paid in conſideration of his making over the property of the ſaid engine to the Commiſſioners of Longitude, for the good of the public. The deſcription which Mr. Ramſden publiſhed, being ſhort and explicit, cannot well be abridged, and the drawings, intended as a guide for other artiſts to work by, are explanatory of all the parts of the engine, as detached from one another; we have therefore given reduced engravings of all the figures, as they were originally arranged, and propoſe to copy the deſcription without any other alteration than what the references to our plates required.

Mr. Ramſden's Engine.—"This engine conſiſts of a large wheel of bell-metal, ſupported on a mahogany ſtand, having three legs, which are ſtrongly connected together by braces, ſo as to make it perfectly ſteady; *fig.* 1. *Plate* VII. of *Engines*, is a perſpective repreſentation of the body thus united. On each leg of the ſtand is placed a conical friction-pulley, whereon the dividing-wheel reſts: to prevent the wheel from ſliding off the friction-pulleys, the bell-metal centre under it turns in a ſocket on the top of the ſtand. The circumference of the wheel is ratched or cut, by a method to be hereafter deſcribed, into 2160 teeth, in which an endleſs ſcrew acts. Six revolutions of the ſcrew will move the wheel a ſpace equal to one degree. Now a circle of braſs being fixed on the ſcrew-arbor, having its circumference divided into 60 parts, each diviſion will anſwer to a motion of the wheel of ten ſeconds; ſix of them will be equal to a minute, &c. Several different arbors of tempered ſteel are truly ground into the ſocket in the centre of the wheel. The upper parts of the arbor, that ſtand above the plane, are turned of various ſizes, to ſuit the centres of different pieces of work to be divided. When any inſtrument is to be divided, the centre of it is very exactly fitted to one of theſe arbors, and the inſtrument is fixed down to the plane of the dividing wheel, by means of ſcrews, which fit into holes made in the radii of the wheel for that purpoſe. The inſtrument being thus fitted on the plane of the wheel, the frame which carries the dividing-point is connected at one end by finger-ſcrews with the frame which carries the endleſs ſcrew; while the other end embraces that part of the ſteel arbor which ſtands above the inſtrument to be divided, by an angular notch in a piece of hardened ſteel; by theſe means both ends of the frame are kept perfectly ſteady and free from ſhake.

The frame carrying the dividing-point, or tracer, is made to ſlide on the frame which carries the endleſs ſcrew to any diſtance from the centre of the wheel, that the radius of the inſtrument to be divided may require, and may be there faſtened by a pair of clamps; and the dividing-point, being connected with the clamps by the double-jointed frame, admits a free and eaſy motion towards or from the centre, for cutting the diviſions without any lateral ſhake. From what has been ſaid it appears, that an inſtrument thus fitted on the dividing-wheel may be moved to any angle by the ſcrew and divided micrometer circle on its arbor, and that this angle may be marked on the limb of the inſtrument with the greateſt exactneſs by the dividing-point, which can only move in a direct line tending to the centre, and is altogether freed from thoſe inconveniences that attend cutting by means of a ſtraight edge. This method of drawing lines will alſo prevent any error that might ariſe from an expanſion or contraction of the metal, during the time of dividing. The ſcrew-frame is fixed on the top of a conical pillar, which turns freely round its axis, and alſo moves freely towards or from the centre of the wheel, ſo that the ſcrew-frame may be entirely guided by the frame which connects it with the centre: by theſe means any eccentricity of the wheel and the arbor would not produce any error in the dividing; and by a particular contrivance, hereafter deſcribed, the ſcrew, when preſſed againſt the teeth of the wheel, always moves parallel to itſelf; ſo that a line joining the centre of the arbor and the dividing-point, continued, will always make equal angles with the ſcrew. The reſt of the parts are repreſented in *Plates* VIII. and IX. of *Engines*, where the figures are numbered in ſucceſſion from 2 to 14 incluſively, which are more eaſily referred to than the figures in the original plates. *Fig.* 2 is a plan of reduced dimenſions, of which *fig.* 3 repreſents a ſection on the line ΠΛ. The large wheel, A, is 45 inches in diameter, and has 10 radii, each ſupported by edge-bars, as ſeen in *fig.* 3. Theſe bars and radii are connected by the circular ring B, 24 inches in diameter, and 3 deep; and, for greater ſtrength, the whole is caſt in one piece in bell-metal. As the whole weight of the wheel, A, reſts on its ring B, the edge-bars are deepeſt where they join it; and from thence their depth diminiſhes, both towards the centre and circumference, as ſeen in the figure. The ſurface of the wheel, A, was worked very even and flat, and its circumference turned true. The ring C, of which a ſection is ſeen in *fig.* 3, made of fine braſs, was fitted very exactly on the circumference of the wheel, and was faſtened thereon with ſcrews, which, after being ſcrewed as tight as poſſible, were well rivetted. The face of a large chuck being turned very true and flat in the lathe, the flattened ſurface, A, of the wheel was faſtened againſt it with hold-faſts; and the two ſurfaces and circumference of the ring C, a hole through the centre, and the plane part round it, together with the lower edge of the ring B, were all turned at the ſame time. D is a piece of hard bell-metal, having the hole that receives the ſteel-arbor made very ſtraight and true. This bell-metal was turned very true on its arbor, and its face, that reſts againſt the wheel, was made very flat, ſo that the ſteel-arbor might ſtand perpendicular to the plane of the wheel: this bell-metal was faſtened to the wheel by ſix ſteel ſcrews. A braſs ſocket, Z, is faſtened on the centre of the mahogany ſtand,

and receives the lower part of the bell-metal piece D, being made to touch the bell-metal in a narrow part near the mouth, to prevent any obliquity of the wheel from bending the arbor: good fitting is by no means neceſſary here, ſince any ſhake in this ſocket will produce no bad effect, as will appear when the cutting-frame is deſcribed. The wheel was then put on its ſtand, the lower edge of the ring, B, reſting on the circumference of the three conical friction-pulleys W, to facilitate its motion round its centre. The axis of one of thoſe pulleys is in a line joining the centre of the wheel and the middle of the endleſs ſcrew, and the other two placed ſo as to be at equal diſtances from each other. F is a block of wood (*fig.* 1.), ſtrongly faſtened to one of the legs of the ſtand; the piece, *g* (*figs.* 1 and 12.), is ſcrewed to the upper ſide of the block, and has half holes, in which the tranſverſe axis, *h*, (*figs.* 1 and 11.) turns; the half holes are kept together by the ſcrews *i*. The lower extremity of the conical pillar, P, (*figs.* 1 and 11.) terminates in a cylindrical ſteel pin *k*, which paſſes through and turns in the tranſverſe axis *h*, and is confined by a cheek and ſcrew. To the upper end of the ſaid conical pillar is faſtened the frame G, (*figs.* 5 and 9.), in which the endleſs ſcrew turns; the pivots of the ſcrew are formed in the manner of two fruſta of cones joined by a cylinder, as repreſented at X, in *fig.* 9. Theſe pivots are confined between half holes, which preſs only on the conical parts, but do not touch the cylindrical parts; the half holes are kept together by ſcrews, *a*, *a*, which may be tightened at any time, to prevent the ſcrew from ſhaking in the frame. On the ſcrew-arbor is a ſmall wheel of braſs, K, having its outſide edge divided into 60 parts, and numbered at every 6th diviſion with 1, 2, &c. to 10. The motion of this wheel is ſhewn by the index, *y*, on the ſcrew-frame G. H repreſents part of the ſtand (*fig.* 1.) having a parallel ſlit in the direction towards the centre of the wheel, large enough to receive the upper part of the conical braſs pillar P, which carries the ſcrew and its frame; and as the reſiſtance, when the wheel is moved by the endleſs ſcrew, is againſt that ſide of the ſlit, H, which is towards the left hand, that ſide of the ſlit is faced with braſs, and the pillar is preſſed againſt it by a ſteel ſpring on the oppoſite ſide: thus is the pillar ſtrongly ſupported laterally, and yet the ſcrew may be eaſily moved from or againſt the circumference of the wheel, and the pillar will turn freely on its axis, to take any direction given it by the frame L, lying over the wheel in *fig.* 1, and ſeen more diſtinctly in *fig.* 13.

At each corner of the piece I, ſeen in *fig.* 1, and alſo detached in *fig.* 8, are as many ſcrews, *n*, of tempered ſteel with poliſhed conical points: two of them turn in conical holes in the ſcrew-frame, near *o*, *fig.* 9; and the points of the other two turn in holes in the piece Q, *fig.* 7: the ſmall end ſcrews, *p*, are of ſteel, which, being tightened, prevent the conical pointed ſcrews from unturning, when the frame is moved. The braſs frame L, *figs.* 1 and 13, ſerves to connect the endleſs ſcrew, its frame, &c. with the centre of the wheel; each arm of this frame is terminated by a ſteel ſcrew, that may be paſſed through any of the holes, *q*, in the piece Q, *fig.* 7, as the thickneſs of the work to be divided on the wheel may require, and are faſtened by the finger-nuts *r*, ſeen in *figs.* 1 and 2. At the other end of this frame is a flat piece of tempered ſteel *b*, wherein is an angular notch; when the endleſs ſcrew is preſſed againſt the teeth of the circumference of the wheel, which may be done by turning the finger-ſcrew S, ſeen in *figs.* 1 and 2, to preſs againſt the ſpring *t*, this notch embraces and preſſes againſt the ſteel-arbor *d*. This end of the frame, too, may be raiſed or depreſſed, by moving the triangular or priſmatic ſlide *u* (*fig.* 14.), which may be fixed at any height by the four ſteel ſcrews *v*. The bottom of this ſlide has a notch *k*, having its plane parallel to the endleſs ſcrew; and by the point of the arbor *d*, reſting in this notch, this end of the frame is prevented from tilting: the ſcrew, S, alſo is kept faſt by the finger-nut *w*, in *fig.* 2.

The teeth on the circumference of the wheel were cut by the following method. Having conſidered what number of teeth on the circumference would be moſt convenient, which in this engine is 2160 or $\overline{360 \times 6}$, I made, ſays Mr. Ramſden, two ſcrews of the ſame dimenſions of tempered ſteel, the interval between the threads of which being ſuch as I knew by calculation would come within the limits of what might be turned off the circumference of the wheel; one of theſe ſcrews, which was intended for ratching or cutting the teeth, was notched acroſs the threads, ſo that the ſcrew, when preſſed againſt the edge of the wheel and turned round, cut in the manner of a ſaw. Then having a ſegment of a circle a little greater than 60°, of about the ſame radius with the wheel, and its circumference made true from a very fine centre, I deſcribed an arch near the edge, and ſet off the chord of 60° on this arch. This ſegment was ſubſtituted for the wheel, and had its edge ratched or indented; and the number of revolutions and parts of the ſcrew head contained within the arch of 60° were counted. The radius was corrected in the proportion of 360 revolutions, which ought to have been in 60°, to the number actually found; and the radius ſo corrected was taken in a pair of beam compaſſes: while the wheel was on the lathe, one foot of the compaſſes was put in the centre, and with the other a circle was deſcribed on the ring; then half the depth of the threads of the ſcrew being taken in the dividers, was ſet from this circle outwards, and another circle was deſcribed cutting this point; a hollow was then turned on the edge of the wheel of the ſame curvature as that of the ſcrew, at the bottom of its threads; the bottom of this hollow was turned to the ſame radius as the outward one of the two circles before-mentioned.

The wheel was now taken off the lathe, and the bell-metal piece D, *fig.* 3, was again ſcrewed to its place, not to be removed any more. From a very exact centre, a circle was deſcribed on the ring C, *fig.* 4, about $\frac{4}{10}$ths of an inch within where the bottom of the teeth would come; this circle was divided with the greateſt poſſible exactneſs, firſt into 5 parts, and each of theſe again into 3; theſe parts were then biſected 4 times; *i. e.* ſuppoſing the whole circumference of the wheel to contain 2160 teeth, a fifth part would be 432, a fifteenth part (or 5 × 3) would be 144, and this laſt number biſected four times would give 72, 36, 18, and 9 reſpectively; but as it was apprehended that ſome inaccuracy would ariſe from quinqueſection and triſection, another circle was deſcribed on the ſame ring, at $\frac{1}{10}$th of an inch within the former circle, and divided by continual biſections into the portions 2160, 1080, 540, 270, 135, $67\frac{1}{2}$, and $33\frac{3}{4}$; and as the fixed wire, to be deſcribed preſently, croſſed both the circles, it was a check on their agreement at every 135 revolutions, and after ratching at every $33\frac{3}{4}$; but as no ſenſible difference was perceived in the two circles, the former was choſen for ratching: and as the coincidence of the fixed wire with an interſection would be more exactly determined than with a dot or diviſion, the interſections in both circles were uſed.

The arms of the frame L, *figs.* 1 and 13, were connected by a thin piece of braſs $\frac{3}{4}$ of an inch broad, having a hole of $\frac{4}{10}$ths of an inch diameter in the middle; acroſs this hole a ſilver wire was fixed exactly in a line to the centre of the wheel; the coincidence of this wire with the interſections was examined by a lens of $\frac{1}{10}$ths of an inch focus, fixed in a tube, that was attached to one of the arms L. Now a handle, or winch, being fixed on the end of the ſcrew-arbor, the diviſion marked 10 on the circle K was ſet to its index, and, by means of a clamp and adjuſting ſcrew for that purpoſe, the interſection marked 1 on the circle C was ſet exactly to coincide with the fixed wire; the ſcrew was then carefully preſſed againſt the circumference of the wheel, by turning the finger-ſcrew S; then, the clamp being removed, the ſcrew was turned by its handle juſt 9 revolutions, till the interſection marked 240, *fig.* 4, came nearly to the wire; the finger-ſcrew S was now turned back, and the dividing ſcrew releaſed from the edge of the wheel, which was here turned back till the interſection marked 2 exactly coincided with the wire; the diviſion 10 on the micrometer circle was then ſet to its index as before, and the ſcrew preſſed againſt the edge of the wheel by the finger-ſcrew S; then, the clamps being removed, the ſcrew was turned a ſecond 9 revolutions, till the interſection marked 1 nearly coincided with the fixed wire; the ſcrew was again releaſed, and the ſame operation was repeated till the teeth were faintly marked all round the circumference of the wheel. The impreſſion was made deeper by thus going three times round; after which the wheel was ratched continually round 300 times in the ſame direction, without diſengaging the ſcrew, when the teeth were found ſufficiently indented. Now, it is evident, that, if the circumference of the wheel were even a whole tooth or ten minutes ſpace greater than the ſcrew would require, this error would, in the firſt inſtance, be reduced to $\frac{1}{240}$th part of a revolution, or two ſeconds and a half; and theſe errors or inequalities of the teeth were equally diſtributed round the wheel at the diſtance of 9 teeth from each other; but, as the ſcrew in ratching had continually hold of ſeveral teeth at the ſame time, and as theſe were conſtantly changing, the above-mentioned inequalities ſoon corrected themſelves, and the teeth were reduced into a perfect equality.

The piece of braſs which carries the wire was now taken away, and the cutting-ſcrew alſo removed, and replaced by the plane one of the ſame dimenſions; on one end of its arbor was put the micrometer circular plate divided into 60, and numbered at every ſix diviſions, as already ſtated; and on the other end was placed a ratchet-wheel of 60 teeth, ſeen in *fig.* 6, which is covered by the hollowed circle *d*, carrying two clicks, that catch upon the oppoſite ſides of the ratchet, when the ſcrew is to be moved forwards. The cylinder S, *figs.* 5 and 9, turns on a ſtrong ſteel arbor F, ſeen in *fig.* 5, which paſſes through, and is firmly ſcrewed to the piece Y; this piece, for greater firmneſs, is attached to the ſcrew frame G by the braces *v*: a ſpiral groove or thread is cut on the outſide of the cylinder S, which ſerves both for holding the ſtring, and alſo for giving motion to the lever J on its centre, *figs.* 9 and 10, by means of a ſteel tooth *n* that works between the threads of the ſpiral. To the lever is attached a ſtrong ſteel pin *m*, *fig.* 10, on which a braſs ſocket *r* turns: this ſocket paſſes through a ſlit in the piece *p*, and may be tightened in any part of the ſlit by the finger-nut *f*: this piece ſerves to regulate a number of revolutions of the ſcrew for each tread of the treadle R, ſeen in *fig.* 1. T, in *fig.* 1, is a braſs box, containing a ſpiral ſpring: a ſtrong gut is faſtened and turned three or four times round the circumference of this box; the gut then paſſes ſeveral times round the cylinder S, *figs.* 1 and 9, and from thence down to the treadle R. Now, when the treadle is preſſed down, the ſtring pulls the cylinder S round its axis, and the clicks laying hold of the teeth on the ratchet, carry the ſcrew round with it, till, by the tooth *n* working in the ſpiral groove, the lever J is brought near the wheel *d*, *fig.* 6, and the cylinder is ſtopped by the ſcrew-head *x*, *fig.* 9, ſtriking on the top of the lever J; at the ſame time the ſpring is wound up by the other end of the gut paſſing round the box T, *fig* 1. Now, when the foot is taken from the treadle, the ſpring in the box unbending itſelf, pulls back the cylinder, the clicks leaving the ratchet and attached ſcrew at reſt till the piece *t* ſtrikes on the end of the piece *p*, *fig.* 10; and the number of revolutions of the ſcrew at each tread is limited by the number of revolutions that the cylinder is allowed to turn back before the ſtop ſtrikes on the piece *p*. When the endleſs ſcrew is moved round its axis with a conſiderable velocity, it will continue that motion a little after the cylinder S is ſtopped; to prevent which angular motion, the angular lever η was made, that when the lever J comes near to ſtop the ſcrew *x*, it, by a ſmall chamfre, preſſes down the piece κ of the angular lever; this brings the other end η of the ſame lever forwards, and ſtops the endleſs ſcrew by the ſteel pin μ ſtriking on its top; the foot of the lever is again raiſed by a ſmall ſpring preſſing on the brace *v*.

Two clamps D, *fig.* 13, connected by the piece *a*, *fig.* 1, ſlide, one on each arm of the frame L, and may be fixed at pleaſure by the four finger-ſcrews ε, which preſs againſt ſteel ſprings, to avoid ſpoiling the arms; the piece *q*, *fig.* 13, is made to turn without ſhake between the two conical pointed ſcrews *f*, *f*, ſet faſt by the finger-nuts N, N. The piece M is made to turn on the piece *q*, by the conical pointed ſcrews reſting in the hollow centres *e*, *e*. As there is frequent occaſion to cut diviſions on inclined planes, for that purpoſe the piece γ, in which the tracer or dividing point is fixed, has a conical axis at each end, which turn in half holes; ſo that when the tracer is ſet to any inclination, it may be fixed there, by tightening the ſteel ſcrews $\beta\beta$."

Subſequently to the time of Mr. Ramſden's dividing engine being conſtructed, Mr. Edward Troughton conſtructed one to anſwer the ſame purpoſe, which it does in the moſt perfect manner; and it was our intention to have deſcribed it alſo in this place, but on application to him for permiſſion to inſpect its parts and manner of operating, we were ſorry to learn that he has pledged himſelf to give an account of it himſelf in another work.

Engine (by Ramſden) *for cutting the Screws of the circular Dividing-Engine.*—We mean not to enter here into the hiſtory of the ſcrew-engine, as it may be, and has been applied to various purpoſes, but to deſcribe the engine made and uſed by Mr. Ramſden for making the individual ſcrews which he uſed for ratching his engine for dividing circles, &c., and for meaſuring the angular diſtance on his circle when ratched. This apparatus, indeed, may be conſidered as an appendage to the other, and therefore ought to be introduced in this place. *Fig.* 1. of *Plate* X. of *Engines*, repreſents this engine as ſeen from one ſide of reduced dimenſions; and *fig.* 2, the ſame as ſeen from above, of the ſame dimenſions. A repreſents a triangular bar of ſteel, to which the triangular holes in the pieces B and C are accurately fitted, and may be fixed on any part of the bar by the ſcrew D. E is a piece of ſteel whereon the ſcrew is intended to be cut, which, after being hardened and tempered, has its pivots turned in the form of two fruſta of cones, as repreſented in the drawings of the dividing-engine. Theſe pivots were very exactly fitted to the half holes F and T, which were kept together by the ſcrews Z. H repreſents a ſcrew of untempered ſteel, having a pivot I, which turns in the hole K. At the other end of the ſcrew is a hollow centre, which receives the hardened conical point of the ſteel pin M. When this point is ſufficiently preſſed againſt the ſcrew, to prevent its ſhaking, the ſteel pin may be fixed by tightening the ſcrews Y. N is a cylindrical nut, moveable on the ſcrew H, which, to prevent any ſhake, may be tightened by the ſcrews O. This nut is connected with the ſaddle-piece P, by means of the intermediate univerſal joint W, through which the arbor of the ſcrew H paſſes. A front view of this piece, with a ſection acroſs the ſcrew-arbor, is repreſented at X, *fig.* 3. This joint is connected with the nut by means of two ſteel ſlips S, which turn on pins between the cheeks T, on the nut N. The other end of theſe ſlips S turn in like manner on pins *a*. One axis of this joint turns in a hole in the cock *b*, which is fixed to the ſaddle-piece, and the other turns in a hole *d*, made for that purpoſe in the ſame piece on which the cock *b* is fixed. By theſe means, when the ſcrew is turned round, the ſaddle-piece will ſlide uniformly along the triangular bar A. K is a ſmall triangular bar of well-tempered ſteel, which ſlides in a groove of the ſame form on the ſaddle-piece P. The point of this bar or cutter is formed to the ſhape of the thread intended to be cut on the endleſs ſcrew. When the cutter is to take proper hold of the intended ſcrew, it may be fixed by tightening the ſcrew *e*, which preſs the two pieces of braſs G upon it. Having meaſured the circumference of the dividing-wheel, it was found to require about one thread in a hundred, coarſer than the guide-ſcrew H. The wheels on the guide-ſcrew arbor H, and that on the ſteel arbor E, on which the ſcrew was to be cut, were proportioned to each other to produce that effect, by giving the wheel L 198 teeth, and the wheel Q 200. Theſe wheels communicated with each other by means of the intermediate wheel R, which alſo ſerved to give the threads on the two ſcrews the ſame direction. The ſaddle-piece P is confined on the bar A by means of the pieces *g*, and may be made to ſlide with a proper degree of tightneſs by the ſcrews *n*.

Engine *for cutting the Screw of Ramſden's Engine for dividing Straight Lines.*—The exactneſs of the ſtraight line engine, as made by Ramſden, depends very much on the correctneſs of the endleſs ſcrew, which requires ſome properties that are not abſolutely neceſſary in the endleſs ſcrew for the *circular engine.* In that, as there are but a few threads of the endleſs ſcrew engaged in the teeth of the wheel, it required only that thoſe threads ſhould have a ſimilar inclination to the axis of the ſcrew all round; but in the ſtraight-line engine, where the whole length of the ſcrew is engaged in the moveable plate, it is neceſſary that the diſtances alſo between the threads ſhould be preciſely the ſame throughout the whole length of the ſcrew: as this is effected in a manner in ſome reſpects different from the mode of cutting the ſcrew we have juſt deſcribed, we ſhall ſubjoin it here, that the reader may take a comparative view of the two methods adopted by that great artiſt Ramſden. In *fig.* 1. of *Plate* XI. of *Engines*, is a plan of the engine for cutting the ſcrew for dividing *ſtraight lines*; and in *fig.* 2, is an elevation of the ſame. The ſection, as given in the original account publiſhed in 1779, does not ſeem to be neceſſary for explaining the engine, and is therefore omitted in our account. A, in *fig.* 1, repreſents a ſtrong circular plate of braſs, having its edge ratched, as deſcribed in our account of the circular dividing-engine; on its centre is firmly fixed the pulley B by four ſcrews, having a groove turned on its cylindrical part, perfectly concentric with the plate A. C, in *fig.* 2, is a ſteel axis two feet long, terminating in a point, whereon it reſts; the upper part of the axis being firmly ſcrewed to the plate A, and turning in the collar D. E repreſents an endleſs ſcrew, *fig.* 1, which being turned on its horizontal axis, moves the circular plate A round its centre: F is a circular divided ſmall plate, or micrometer-head, which may be turned with or without the endleſs ſcrew; and on the other end of this ſcrew-arbor is a large pinion *a*, with levelled teeth on its edge, together with the winch X to turn it by. G, ſeen in both figures, is a triangular bar of ſteel, which paſſes over the circular plate A, and is firmly ſcrewed to the frame of the engine at H, *fig.* 1, and I, *fig.* 2. K is a piece of ſteel forming the arbor of the ſcrew intended to be cut, having a wheel L, on one end acting with the pinion *a* before-mentioned. M and N, *fig.* 1, are two ſtrong pieces of braſs, in which the arbor juſt mentioned turns, and are firmly fixed to the triangular bar G, by means of the ſcrews *n*, *n*, ſeen at I, in *fig.* 2. O, ſeen in both figures, is a piece of braſs that ſlides on the triangular bar G, the two extremities of which are made exactly to fit the bar; it ſlides regularly thereon, and is prevented from riſing by the two ſpring pieces *c*, *c*; near one end of the piece O is an angular groove *q*, *fig.* 1, that holds the tool by which the threads are cut, and is pointed with a diamond, in order to cut the ſteel after it is hardened and tempered: the cock *w* ſerves to faſten the tool, which may be ſet to take proper hold on the ſteel by turning the finger-ſcrew *s*, and is fixed there by the ſcrew *v*.

To make a perfect ſcrew, it is only required to give the point that cuts the threads an uniform motion parallel to itſelf, and alſo to the axis of the intended ſcrew, and that this motion be proportioned to the revolutions of the intended ſcrew as the number of threads may require. To effect this, a piece of thin tempered ſteel *t*, exactly of the ſame thickneſs throughout, is faſtened to the ſlide O at *r*; the other end of the ſpring being faſtened to the pulley B in the groove: now while the circle A, with the pulley, is turned round its centre by turning the endleſs ſcrew to the right hand, the ſpring *t* draws the ſlider O, with the attached cutter *q*, along the triangular bar; at the ſame time the ſteel-arbor K of the ſcrew to be cut revolves by means of the communication of its wheel L with the revolving pinion *a*.

The ſcrew, E, of the circular plate has 20 threads *per* inch, therefore if the number of teeth on the pinion, *a*, be to the number in the wheel L, as the number of teeth on the circular plate, A, is to the number of 20ths of an inch round the circumference of the pulley B, allowing for part of the thickneſs at the ſpring *t*, the ſpaces between each of the threads of the ſcrew to be cut will be alſo 20ths of an inch. The ſize of the pulley, B, was determined thus: the endleſs ſcrew, E, being diſengaged from the circular plate A, the ſlider, O, was drawn back till the end of it came nearly to the piece M; the endleſs ſcrew was again engaged in the plate A; then having two very ſmall dots on the ſlider O, ſet off parallel to one ſide, at exactly five inches diſtance from each other, the ſlider was moved by turning the endleſs ſcrew E, till one of its dots was biſected by a ſmall ſilver wire fixed acroſs a hole made in a thin piece of braſs faſt to the piece N; then O on the micrometer head, F, being put to the index without moving the ſcrew, the pulley was tried and reduced, till juſt 600 revolutions of the endleſs ſcrew, E, brought the ſecond dot to be exactly biſected by the fixed wire. Theſe biſections were examined by a lens of half an inch focus, ſet in a ſmall braſs tube, that was fixed perpendicularly over the wire.

Engine *for dividing ſtraight Lines, by Ramſden.*—When Mr. Ramſden had ſucceeded in dividing ſextants, &c. by his circular dividing engine, and was rewarded by the honourable Board of Longitude, he turned his mind towards

wards the contrivance of an engine that would divide ſtraight lines into any number of aſſignable parts, and that might be uſeful in laying down with extreme accuracy the lines of ſines, tangents, ſecants, &c. on ſectors and plane ſcales. The project was realized, and the account was ordered to be publiſhed by the Board of Longitude, in the year 1779. We do not find, however, that the original model, which we come now to deſcribe, has been found deſirable to copy by ſucceeding mathematical inſtrument makers: more ſimple and leſs expenſive means have been adopted, which are found to anſwer practically as good a purpoſe. A beam-compaſs, aided by proper tables, is quite accurate enough for the niceſt purpoſes of dividing unequal, as well as equal, diviſions by biſection; and a pattern once carefully laid down can be uſed, for transferring the diviſions on the common caſes of inſtruments, with greater facility than the engine itſelf can be worked; and, provided great care be taken to prevent the parallax of the transferring point, the accuracy will be ſufficient for all ordinary uſes. This engine, which profeſſes to divide any line without an error of $\frac{1}{4000}$th of an inch, has its principal parts repreſented in *Plate* XII. of *Engines;* where *fig.* 1, repreſents a plan of the dividing portion, as ſeen from above; *fig.* 2, an elevation of the ſame ſeen acroſs; and *fig.* 3, the under ſide of *fig.* 1, when turned up. The original account contains ſome ſections, which are more uſeful for the workmen as patterns, than for a general deſcription, which may diſpenſe with them altogether. A, in *fig.* 1, is a ſtrong braſs plate, 27 inches long, 4 broad, and $\frac{7}{10}$ths thick; worked exceedingly flat, and of the ſame thickneſs throughout, with its two edges parallel. One of theſe edges is ratched, or cut into teeth, of which there are juſt 20 in an inch, and is moved by an endleſs ſcrew, containing juſt 20 threads in an inch, which actuates the teeth. (See ENGINE *for cutting the Screw of Ramſden's ſtraight-line Engine.*) Each revolution of the endleſs ſcrew round its axis will move the plate $\frac{1}{100}$ths of an inch along an iron frame, hereafter to be deſcribed. A micrometer head is fixed at one end of the ſcrew arbor, divided into 50 diviſions, which, by means of a vernier ſubdividing into 5 parts, meaſures $\frac{2}{10000}$ths of an inch along the frame. Any rule or other inſtrument may be faſtened on this plate, and may have a line drawn on it divided by a point or tracer, fixed in a proper frame, whereby it has a rectilinear motion without any lateral ſhake. When lines are to be divided by diviſions not commenſurable with Engliſh inches, which conſtitute the ſcale, the line to be ſo divided may be laid down, not parallel to the plate A, but obliquely, ſo as to make an angle with it, or become the hypothenuſe line of a right-angled triangle; which line, by calculation, ſhall be to the baſe as the denomination of meaſure, when longer, is to the Engliſh inch; that is, as the ſecant is to the radius of the triangle, provided the tracer draws lines at right angles to the ſide of the plate; but if the traced lines be at right angles to the line to be divided, then the diviſions on that line will be ſhorter than they would be on a parallel line of the plate, and in the proportion of the co-ſine of the angle of inclination to radius. In order to adjuſt the inclination of a ruler laid on the plate A, two sectoral portions of a circle are laid down on one of its ends, with an extent from the point J, near the fixing ſcrews on the edge of this plate. The outer ſector is divided into proper degrees, and is numbered from 1 to 9, which degrees are ſubdivided into 6, or 10 minutes ſpaces; but the inner ſector is divided into the proportion of the coſines to radius 10,000, and its diviſions are numbered 10, 20, 30, &c. to 140. The uſe of this contrivance will be beſt underſtood by an example: for inſtance, if a line of $9\frac{999}{1000}$ were to be divided into the ſame number of diviſions, and in the ſame manner as if it were 10 inches long exactly; put the ruler to be divided to the cutting frame, hereafter deſcribed, and turn the handle, T, that moves the apparatus, till the ſame edge of the ruler cuts the central point J, and the firſt diviſion from the O of the inner ſector; then ſcrew the ruler faſt to the plate A, and when it has moved ten inches in its own direction, the whole length of the diviſions on the line divided will be only $9\frac{999}{1000}$ inches, though the divided ſpaces will be reſpectively equal among themſelves. It is not neceſſary for us to particularize the precautions taken, in making all the ſpaces of the teeth ratched equal to each other, during the act of ratching, which was done with a notched ſcrew: this was done by means of points previouſly made and examined, with a wire at every 16 revolutions of the ſcrew, till the teeth were a little indented to guide the ſcrew along the whole line by continual revolutions, as was the caſe in the circular dividing inſtrument, more particularly deſcribed, becauſe found more particularly uſeful. B, in *fig.* 1, is a ſtrong iron frame, 43 inches long, having two edges, *a* and *b*, riſing half an inch above its ſurface; theſe two edges are made very ſtraight, and are in the ſame plane; the inſide of the edge *a* is alſo made as ſtraight as poſſible. The plate, A, ſlides on the two edges of the iron frame; beneath it are two ſprings, *c*, *c*, ſeen in *fig.* 3, each faſtened at the extreme ends to the plate A, by the ſcrews, *s*, *s*; at the other end of each ſpring is a roller, *e*, of tempered ſteel, turning on an axis in theſe ſprings; there is alſo a third roller, *d*, of tempered ſteel, let into the iron frame, not ſeen, near where the threads of the endleſs ſcrew act; this roller has a long axis, ſo ſituated that it may be raiſed or depreſſed as occaſion may require, to bear the weight of the plate A, and rule or inſtrument placed on it. C, in *figs.* 1 and 2, is the endleſs ſcrew of tempered ſteel, with pivots of two fruſta of inverted cones, ſimilar to thoſe deſcribed in the engine for dividing circles, &c. which turn in adjuſtable half holes in braſs cocks ſcrewed to the iron frame. G, G, in *fig.* 3, are two ſmall ſteel frames turning on centres, *k*, faſtened to the underſide of the plate A, and equidiſtant from the edge of it; in each frame is a roller, *y*, of tempered ſteel, turning very concentric with their pivots, and exactly of the ſame diameter. The two ſmall frames are connected together by the long braſs bar E, which turns on a ſtud in each frame, and which preſerves its paralleliſm, on the principle of a common parallel ruler. This apparatus ſerves to preſs the edge of the plate, A, with a motion parallel to itſelf againſt the threads of the endleſs ſcrew. On the end of the plate, A, is a ſpring of tempered ſteel, acting as a bent lever. The ſpring end of this lever has a ketch which paſſes under the head of the ſtud *l*, that is on the end of the connecting piece E. While the other end of the lever is preſſed gradually down towards the plate A, by turning the finger-ſcrew F, the connecting piece, E, is drawn forward, ſo that the ſteel rollers, borne by the ſprings T, in *fig.* 3, preſſing againſt the edge, *a*, of the iron frame, in *fig.* 1, may force the ſide of the plate againſt the endleſs ſcrew.

Beſides the micrometer head, already named, the arbor of the dividing ſcrew, which has its threads ſimilar to thoſe of the notched ratching ſcrew, has at its oppoſite end two ſets of ratched wheels; one ſet for turning the ſcrew, and the other ſet for ſtopping it at the proper times. Theſe ſets are each compoſed of three wheels, of which one has 32 teeth, another 48, and the third 50, which afford the means of ſubdividing the inch into ſpaces of different denominations; thoſe wheels uſed in ſtopping the ſcrew are ratched, with the teeth pointing in a contrary direction to thoſe of the wheels for putting it in motion. I repreſents a cylinder of braſs, having on one end two ſteel rings, *a* and *b*, with their contiguous edges cut into ratched teeth, in contrary directions, ſo as to fit each other as ſeen in the figure; on one of theſe rings is an index, and the other has its teeth numbered 10, 20, &c. up to 50; the other end of the cylinder is made hollow, and contains one of the ſets of ratched wheels, already named. There are two ſlits oppoſite each other, pierced through the hollow part of the cylinder W; in each of which ſlits is a click turning on an axis, and preſſed into the teeth of the ratched wheel by a ſmall ſpring.; theſe clicks may be moved along their axis, ſo as to catch in any one of the three ratched wheels, and may be faſtened at that place by a ſmall tightening ſcrew *s*. The cylinder I, with the clicks, &c. turns on a ſteel axis, attached to the piece K, in a line with the axis of the endleſs ſcrew. Motion is given to this cylinder round its axis by a piece of catgut, which hath one end faſtened to the ratched ring *b*; and the other end, after paſſing four or five times round the cylinder, is faſtened to a treadle, and, on preſſing the treadle down, the clicks, *s*, catch in the teeth of one of the ratched wheels; by which contrivance the cylinder I, together with the endleſs ſcrew, is turned round its axis, and its motion carries the plate, A, along the iron frame, and at the ſame time winds up the ſpiral ſpring *u*; but on releaſing the treadle, the ſaid ſpring unbends itſelf, the clicks quit the ratched wheel, and leave the endleſs ſcrew at reſt, whilſt the cylinder, I, turns in an oppoſite direction, and raiſes the treadle to its former ſituation. V, in *fig.* 2, is a ſmall ſquare bar of ſteel, having both its extremities cylindrical; theſe cylinders move in holes lined with hardened ſteel, one in the piece D, and the other in the piece K. This bar carries three different pieces, which are of tempered ſteel; the middle one, *t*, is made to lie in the interval between the threads of the ſcrew cut on the cylinder, and paſſes nearly half round its circumference: it is kept in the threads by a ſpring, *e*, that preſſes on a piece, *q*, ſcrewed to the iron frame; this piece being attached to the bar, V, by a ſcrew, turning the cylinder, I, on its axis, will give a longitudinal motion to the bar V. The upper end of the piece *f*, *fig.* 2, is formed into a hook, and may be ſet to catch in the teeth of any of the ratchet wheels, and then be faſtened to the bar, V, by a ſcrew *i*; towards the other end of the bar is a piece *j*, which ſerves to ſtop the cylinder in turning back, ſo as to limit the number of revolutions and parts of a revolution required, and is faſtened to any required place on the bar, V, by the finger-ſcrew *s*.

When the engine is uſed, the treadle is preſſed down, and the catgut turns the cylinder I; in the mean time, the piece, *t*, moves along the thread till a ſtud, *r*, on the cylinder, ſtriking on the top of the curved piece *t*, bends the ſpring *e*, until that piece reſts on the piece *q*; by bending this ſpring, the ſquare bar is turned a little on its axis, and pulls the hook, *f*, into the teeth on the ratched wheel R: then the treadle being releaſed, the ſpiral ſpring turns back the cylinder till the piece, *j*, is brought under the ſtop on the ratchet ring *b*. The parts of a revolution are regulated by ſetting the number required on the ratchet ring, *b*, to the index on the fixed ring *a*; each of the teeth anſwers to the motion of $\frac{1}{1500}$th of an inch of the plate A; and the number of revolutions, each of which moves the plate, A, $\frac{5}{10}$ths of an inch, is regulated by ſetting the piece, *j*, on the bar. I, in *fig.* 1, repreſents the ſteel frame in which the tracer is fixed; this frame turns between the conical points of two ſcrews, *n*, *n*, of tempered ſteel, which are ſcrewed in the frame Q, *fig.* 2; there are alſo two ſimilar ſcrews in the ſame frame Q, at *m*, *m*; the points of theſe ſcrews, which are alſo of tempered ſteel, turn in conical holes in the piece P; by means of this parallel motion, the tracing point, by which the dividing lines are cut, will always deſcribe the ſame line without any lateral bending; the tracer is put on the hole in the axis *b*, *fig.* 1, and is fixed there by the four tightening ſcrews, *f*, that preſs the holding piece, *c*, againſt the flattened part of the axis of motion. This ſmall axis, which has its pivots formed of double cones, turns between half holes, and may be fixed when the tracer is ſet to any required inclination, by tightening the ſcrews of preſſure, *s*, *s*, *s*, *s*. Beſides theſe parts of the engine, there is a braſs ruler made as an appendage for ſetting the line to be divided in its true ſituation, but is not neceſſary to be particularly deſcribed: this ruler may be ſet parallel to the edge of the plate A, or to any angle of inclination, by turning the handle T, which moves the piece P, with the cutting frame and ruler, on the centre *x*; and the required poſition may be rendered permanent by tightening the capſtan ſcrew *p*.

ENGINE-*Shaft*, in *Mining*, is generally applied to the ſhaft or well wherein the pumps are erected for freeing a mine of its water; but in diſtricts where the mines are relieved of water by ſoughs, as in the mountainous part of Derbyſhire, it is common to find the ſhafts at which they draw ore by a horſe-gin, called the engine-ſhaft, and the gin itſelf an engine.

ENGINE *to draw Fuzes*, in *Gunnery*, conſiſts of a wheel with a handle to it, to raiſe a certain weight, and to let it fall upon the driver, by which the ſtrokes become more equal.

ENGINE *to draw Fuzes* has a ſcrew fixed upon a three-legged ſtand, the bottom of which has a ring to place it upon the ſhell; and at the end of the ſcrew is fixed a hand-ſcrew, by means of a collar, which, being ſcrewed on the fuze, by turning the upper ſcrew, draws out or raiſes the fuze.

ENGINEER, or INGINEER, in its general ſenſe, is applied to a contriver or maker of any kind of uſeful engines or machines.

In its more proper ſenſe, it denotes an officer in an army or fortified place, whoſe buſineſs it is to contrive and inſpect attacks, defences, works, &c. The term engineer is ſaid to be of modern date, and to have been firſt uſed in the year 1650, when one Cap. Thomas Rudd had the title of chief engineer to the king. In 1634 an engineer was called camp-maſter general, and ſometimes engine-maſter, being always ſubordinate to the maſter of the ordnance.

An engineer ſhould be an able and expert mathematician, particularly verſed in military architecture and gunnery; being often ſent to view and examine the places intended to be attacked; to chooſe out and ſhew the general the weakeſt place; to draw the trenches, aſſign the places of arms, galleries, lodgments on the counterſcarp and half-moons; conduct the works, ſaps, mines, &c. and appoint the workmen their nightly taſk; he is alſo to make the lines of contravallation; with the redoubts, &c.

Under the eſtabliſhment of the office of his majeſty's ordnance in England, the corps of *royal engineers* conſiſts of one colonel in chief, one colonel in ſecond, three colonels commandant, ſix colonels, 12 lieutenant-colonels, 27 captains, 28 ſecond-captains, 55 firſt-lieutenants, 28 ſecond-lieutenants, an inſpector-general of fortifications, his deputy brigade-major, adjutant, and quarter-maſter.

The eſtabliſhment of the corps of *invalid engineers* comprehends a colonel, lieutenant-colonel, captain, captain-lieutenant and captain, firſt-lieutenant and ſecond-lieutenant.

The corps of *royal engineers* in Ireland conſiſts of a director, colonel, lieutenant-colonel, major, captain, captain-lieutenant, and captain, and two firſt-lieutenants. See Ordnance.

Engineers, *Civil*, a denomination which compriſes an order or profeſſion of perſons highly reſpectable for their talents and ſcientific attainments, and eminently uſeful under this appellation, as the canals, docks, harbours, light houſes, &c. amply and honourably teſtify. This order of artiſts is ſaid to have commenced in this country about the year 1760, at which period the advancement of the arts and ſciences was ſingularly rapid. In 1771, Mr. Smeaton, ſo well known in this department of ſcience, projected and eſtabliſhed an aſſociation, or ſociety of engineers. During an interval of 20 years, the number of members of this ſociety increaſed to 65, of whom 15 were real engineers, and the reſidue being compoſed either of amateurs, or of ingenious workmen and artificers. In May 1792 this ſociety was diſſolved in conſequence of an unpleaſant circumſtance, which had interrupted its harmony; but a renewal of it, under a better form, was ſoon intended, though not accompliſhed during the life-time of Mr. Smeaton. His death happened in October 1792, and the firſt meeting of the new inſtitution, entitled "The Society of Civil Engineers," was held on April 15, 1793, by Mr. Jeſſop, Mr. Mylne, Mr. Rennie, and Mr. Whitworth. According to the new conſtitution of the ſociety, it is divided into three claſſes. The firſt claſs, as ordinary members, conſiſts of real engineers. The ſecond claſs, as honorary members, is compoſed of men of ſcience, and gentlemen of rank and fortune, who have attended to the ſubject of civil engineering. The third claſs, as honorary members alſo, conſiſts of artiſts, whoſe profeſſions and employments are connected with what is called civil engineering. The meetings are held at the Crown and Anchor, in the Strand, every other Friday, during the ſeſſion of parliament. See Reports of the late Mr. John Smeaton, F.R.S. &c. vol. i. 4to. 1797.

ENGISO'MA, from εγγιζω, *to draw near*, in *Surgery*, an inſtrument formerly uſed by ſurgeons in caſes of fractures of the ſkull. Hence, the word has been applied to ſuch fractures of the cranium as are attended with a depreſſion of the bone in the middle, ſo as to produce preſſure on the membranes of the brain.

ENGLAND, in *Geography*. The ſouthern, moſt opulent, and moſt important part of Britain, has been diſtinguiſhed among European nations, ever ſince the days of venerable Bede, by the appellation of "Anglia," or England; which has been generally aſcribed to the Angles, who conquered and took poſſeſſion of a conſiderable part of the country. (See Anglen, Angles, and *Cimbric* Chersonesus.) England is bounded on the eaſt by the German ocean; on the ſouth by the Engliſh channel; on the weſt by St. George's channel; on the north by the Cheviot hills, by the river Tweed, and an imaginary line extending ſouth-weſt to the Frith of Solway. The extent of England and Wales is eſtimated at 49,450 ſquare miles, and if we allow the population to be 9,500,000, the number of inhabitants to a ſquare mile will be 192. The original population of England is involved in obſcurity; but as far as it can be traced by any authentic records of hiſtory, it ſeems to have conſiſted of a tribe of Celtæ (ſee Celts), denominated Gael or Southern Celts, and diſtinguiſhed by the Welſh under the appellation of "Guydels," who migrated hither from the neareſt ſhores of France and Flanders. Theſe ſouthern Celts were compelled to evacuate the country, and to retire to Ireland, by another tribe, compoſed of the Cimbri of the north, whence the modern Welſh derive their origin and name of Cymru. The Cimbri, or Northern Celts, were diſplaced by the Scythians, or Goths, who, at a period long preceding the Chriſtian era, ſettled in that part of Gaul which is neareſt to Great Britain, and acquired the provincial denomination of Belgæ. (See Belgæ.) We learn from Cæſar (lib. v. c. 10.) that the primitive inhabitants were driven into the interior parts of the country by Belgic colonies, which occupied the regions on the ſouth-eaſt, probably about three centuries before the Chriſtian era. Theſe Belgæ ſeem to have conſtituted the chief anceſtors of the Engliſh nation; but during a ſubjection of four centuries to the Roman power, after Britain was rendered a Roman province by the talents and virtue of Agricola, (ſee Agricola,) they loſt their primitive valour, and were unable to contend with their fierce invaders from Scotland and Ireland. In theſe circumſtances the continent ſupplied them either by accident or at their own requeſt, with new emigrants. The Jutes arrived in the year 449, and about the year 460 founded the kingdom of Kent. The Saxons firſt appeared in 477, and the kingdom of the South Saxons commenced about this period. The Weſt Saxons arrived in the year 495, and the Eaſt Saxons in the year 527. The Angles, who gave their name to the country, were led by the valiant Ida to Bernicia, in the year 547. The Eaſt Angles took poſſeſſion of Norfolk in 575; and the coaſts on the ſouth and eaſt were over-run by them. Hence they ſoon penetrated into the interior of the country, and in 585 founded the kingdom of Mercia, which was the laſt of the heptarchy. (See Heptarchy and Saxons.) The kingdom of Northumberland exiſted under its peculiar ſovereign, the laſt of whom was Eric, till the year 950; and the three counties of modern Northumberland, Cumberland, and Weſtmoreland, were regarded at that period, when Domeſday-book was compiled, as part of Scotland. Bernicia (which ſee) extended at one period to the Frith of Forth; but in the later Saxon times the boundaries of England on the north fell conſiderably within the preſent extent. On the weſt the Welſh were reſtricted by Offa's dyke, (ſee Dyke,) which extended from the river Wye, through the counties of Hereford and Radnor, into that of Montgomery, where it entered North Wales. It afterwards paſſes by Chirk-caſtle to the river Dee, and terminates in the pariſh of Mold. During the Norman period, the northern limits of England were extended to their preſent circuit. Cumberland and Weſtmoreland were wreſted from the Scots, and the provinces north of the Humber were completely incorporated. The dominion of the Danes commenced in the year 1016; but returned to the Saxon line in the year 1042. On the death of Edward the Confeſſor, the conqueſt, as it is called, under William the Norman, took place in 1066. (See Conquest.) For a farther account of the hiſtory of England, ſee Britain, and the ſequel of this article.

The antiquities of England are diſtributed by Mr. Pinkerton (Geog. vol. i.) into ſix claſſes, *viz.* thoſe belonging to the primitive Celtic inhabitants; thoſe of the Belgic colonies; thoſe of the Romans; thoſe of the Saxons; relics of the Danes; and Norman monuments. It is not eaſy, ſays our author, to diſcriminate the remains of the earlieſt inhabitants from thoſe of the Druidic period, which he ſuppoſes to have originated with the Phœnician factories, eſtabliſhed in wooden fortreſſes on the coaſt, which was the uſual practice of commercial nations, when trading with a ſavage or barbarous race. The tenets of Druidiſm correſpond, as he conceives, with the little that is known of Phœnician mythology, in the diffuſion of which the miſſionaries of theſe refined people might be not a little zealous. However this be, the ancient authors, from whom we derive our only authentic information concerning the Druids, minutely deſcribe their religious rites; but they are altogether ſilent concerning any monuments of ſtone being uſed among them. On the contrary, they mention gloomy groves, and ſpreading oaks, as the only ſcenes of the Druidic ceremonies. (See Druids.) Nevertheleſs, our learned antiquarian, Borlaſe, refers to the claſs of Druidic monuments ſuch as follow, *viz.* ſingle ſtones erect; rock idols and pierced ſtones; rocking-ſtones uſed as ordeals; ſepulchres of two, three, or more ſtones; circular temples, or rather circles of erect ſtones; rock-baſons, ſuppoſed to have been uſed in the expiations of the Druids; and caves, uſed as places of retreat in time of war. But Mr. Pinkerton obſerving, that moſt of theſe relics may be found in Germany, (where no Druids exiſted,) and Scandinavia, thinks it hazardous to pronounce whether they be Gothic or Celtic. It is moſt probable, he imagines, that the earlieſt inhabitants, like others who exiſt in the infancy of ſociety, made uſe of wood, not ſtone, in their religious, as well as in their domeſtic ſtructures. He thinks it moſt reaſonable to refer monuments of this kind to a more advanced ſtage of ſociety, when the Belgic colonies introduced agriculture, and had made ſomewhat farther progreſs in the rude arts of barbariſm. See Barrow and Cromlech, Stone-henge, &c.

The Roman relics are amphitheatres, caſtles, ways, or roads, pavements, hypocauſts, walls, inſcriptions, altars, &c. &c. which are deſcribed under theſe articles reſpectively; to theſe we might add coins, gems, weapons, ornaments, and the like. The Saxon antiquities in England are chiefly edifices, ſacred or ſecular, caſtles, vaults, ſhrines, illuminated manuſcripts, &c. The relics of the Danes are caſtles, ſtones with Runic inſcriptions, and camps, which were conſtructed in a circular form, like thoſe of the Belgæ and Saxons, while thoſe of the Roman armies are diſtinguiſhed by their ſquare form. The Norman monuments are reputed to commence after the conqueſt, and to extend to the 14th century, when that which is called the rich Gothic began to appear. This latter was ſupplanted, in the 16th century, by the mixed, which in its turn yielded to the Grecian. The Norman ſtyle in general far exceeds the Saxon in the ſize of the edifices, and the decorations of the parts. The churches became more extenſive and lofty; and though the windows retain the circular arch, they are larger and more diverſified, the circular doors are feſtooned with more freedom and elegance; and uncouth animals begin to yield to wreaths of leaves and flowers. The ſolitary keep, or tower, of the Saxon caſtle, is ſurrounded with a double wall, incloſing courts and dwellings of large extent, defended by turrets and double ditches, with a ſeparate watch-tower, called the Barbican. Among others the cathedrals of Durham and Wincheſter may be mentioned as venerable monuments of Anglo-Norman architecture; and the caſtles are numerous and well-known. What is called the Gothic, or pointed arch, is generally ſuppoſed to have firſt appeared in the 13th century; and in the next it became univerſal in religious edifices. The windows diffuſed to great breadth and loftineſs, and divided into branching interſtices, enriched with painted glaſs, the cluſtering pillars of exceſſive height, ſpreading into various fret-work on the roof, conſtitute, with decorations of ſmaller note, what is called the rich Gothic ſtyle, viſible in the chapel of King's college at Cambridge, and many other grand ſpecimens in this kingdom. The ſpire correſponds with the interior; and begins, about the 13th century, to riſe boldly from the ancient tower, and diminiſhes from the ſight in a gradation of pinnacles and ornaments. See Gothic.

England is now diſtributed into 40 ſhires or counties. See County and Shire.

		Population.	Chief Towns.
Six Northern Counties.	Northumberland,	157,101	Newcaſtle.
	Cumberland,	117,230	Carliſle.
	Durham, —	160,361	Durham.
	Yorkſhire,	563,953	York.
	Weſtmorland,	41,617	Appleby.
	Lancaſhire,	672,731	Lancaſter.
Four bordering on Wales.	Cheſhire,	191,751	Cheſter.
	Shropſhire,	167,639	Shrewſbury.
	Herefordſhire,	81,191	Hereford.
	Monmouthſhire,	45,582	Monmouth.
Twelve Midland.	Nottinghamſhire,	140,350	Nottingham.
	Derbyſhire,	161,142	Derby.
	Staffordſhire,	239,153	Stafford.
	Leiceſterſhire,	130,081	Leiceſter.
	Rutlandſhire,	16,356	Okeham.
	Northamptonſhire,	131,757	Northampton
	Warwickſhire,	208,190	Warwick.
	Worceſterſhire,	139,333	Worceſter.
	Glouceſterſhire,	250,809	Glouceſter.
	Oxfordſhire,	109,620	Oxford.
	Buckinghamſhire,	107,444	Ayleſbury.
	Bedfordſhire,	63,393	Bedford.
Eight Eaſtern.	Lincolnſhire,	208,557	Lincoln.
	Huntingdonſhire,	37,568	Huntingdon.
	Cambridgeſhire,	89,346	Cambridge.
	Norfolk,	273,371	Norwich.
	Suffolk,	210,431	Ipſwich.
	Eſſex,	226,437	Chelmsford.
	Hertfordſhire,	97,577	Hertford.
	Middleſex, (capital excluded,)	535,329	London.
Three Southern.	Surry,	269,043	Guilford.
	Kent,	307,624	Maidſtone.
	Suſſex,	159,311	Lewes.
Four Southern.	Berkſhire,	109,215	Reading.
	Wiltſhire,	185,107	Saliſbury.
	Hampſhire,	219,656	Wincheſter.
	Dorſetſhire,	115,319	Dorcheſter.
Three Southern.	Somerſeſhire,	273,750	Taunton.
	Devonſhire,	343,001	Exeter.
	Cornwall,	188,269	Launceſton.

For a more particular account of each county, ſee the ſeparate articles.

It is hardly neceſſary to mention, that London is the capital of England, or in this place to enumerate its principal towns, which are deſcribed under their ſeveral appellations. Canterbury and York are the ſees of archbiſhops: Oxford and Cambridge are univerſities. The principal rivers of England are the Thames, the Severn, the Humber, the Merſey, &c. which ſee reſpectively. For an account of our inland navigation, ſee Canal; and for our bridges, ſee Bridge. The mountains, with their productions, will occur under that article. For the climate, ſee Britain; and of the ſoil, and agriculture, &c. an account will be found under the name and deſcription of each county; and under the appropriate terms of cattle, dog, hog, horſe, ſheep, goats, &c. and wheat, rye, barley, oats, apples and cyder, pears and perry. Our foreſts (ſee Forest) anciently abounded in ſtags and rein-deer, as the cultivated lands now do with ſheep and cattle. The principal wild animals, wolves and bears having been totally deſtroyed, are the fox, wild-cat, badger, fitchet, martin, otter, ſquirrel, &c. Among our birds of prey may be reckoned the black eagle, and many kinds of hawks. Our ſmalleſt bird is the gold-creſted wren, and our largeſt the buſtard. Our poultry ſeem to have been originally derived from Aſia; our peacocks from India; our pheaſants from Colchis; the guinea fowl from Africa; and our turkeys from America. One of the moſt ſingular of our water-fowl is the long-legged plover, and the moſt uſeful is the mallard or wild duck, chiefly abounding in the fens of Lincolnſhire. The reptiles of England are the coriaceous tortoiſe, frogs, toads, and ſeveral kinds of lizards; among our ſerpents are the viper, which alone is venomous, the ringed ſnake and the blind worm, all of which, together with other ſpecies, are enumerated and deſcribed in their proper places. Our edible ſea-fiſh are very numerous; among which we may reckon the turbot, dorie, ſeal, cod, plaiſe, ſmelt, mullet, &c. Herrings and mackarel extend to moſt parts of the kingdom; but pilchards are reſtricted to the coaſts of Cornwall. The whale ſeldom appears on the Engliſh coaſt, nor the dolphin; but the porpoiſe is not uncommon. Our principal river fiſh comprehend the ſalmon and trout. The lobſter is found on moſt of the rocky coaſts, particularly of Scarborough. The craw-fiſh, muſcle and oyſters, are abundant. The flora of Britain contains as great a variety of genera and ſpecies as any other country of equal extent; and thoſe that are moſt worthy of notice, on account either of their variety or utility, or other peculiar circumſtances attending them, are enumerated and deſcribed under their proper heads. Our native fruits are few, but others have been introduced and our own improved, ſo that plumbs, cherries, peaches, nectarines, apricots, figs, grapes, &c. are by the ſkill and care of the Engliſh gardeners raiſed in the greateſt plenty and variety. The oak and beech are natives of England: the elm is probably an exotic; but there are few plants in any part of the known world, which have not been introduced into our plantations, nurſeries, green-houſes, and hot-houſes.

The conſtitution of England is a limited monarchy counterpoiſed by two ſenates, one of hereditary peers, the other of repreſentatives choſen by the people. (See CONSTITUTION, CROWN, KING, COMMONS, PEERS, PARLIAMENT.) For an account of the judicature of England, we refer to the articles JUDGE, JURY, COURT, CIRCUIT, JUSTICE, SHERIFF, &c. The eſtabliſhed religion of England is that of the reformed church under the adminiſtration of the king, as ſupreme head, archbiſhops, biſhops, deans, archdeacons, rectors, vicars, curates, &c. See each of theſe titles. See alſo CHURCH, CLERGY, CONVOCATION, *Eccleſiaſtical* COURTS, &c. Beſides thoſe who are members of the eſtabliſhed church, England abounds with diſſidents or diſſenters of various deſcriptions. See theſe terms, and alſo INDEPENDENTS, PRESBYTERIANS, BAPTISTS, QUAKERS, METHODISTS, PAPISTS, &c. For the army and navy of England; its manufactures and commerce; its land and revenue; its population; and various other particulars; ſee BRITAIN, and the appropriate articles in this work.

ENGLAND, *hiſtory of.* The principal events belonging to the hiſtory of our country will be found under the names of the ſeveral kings who have reigned over it. To the articles attached to thoſe names we might refer generally for a compreſſed detail of all the changes and revolutions to which England has, at its ſeveral periods, been ſubject; but in conformity to the plan ſketched out in the article BRITAIN, we muſt in this place give a very brief outline of the hiſtory of England, from the Norman conqueſt to the acceſſion of James I.; and likewiſe the hiſtory from that period to the preſent times. After the conqueſt, our hiſtory is repreſented in ſo clear a light, as leaves little either obſcure or uncertain. The only difficulty we ſhall find will be in condenſing into a ſmall ſpace the leading facts that are not immediately connected with the lives of the ſovereigns.

The Saxon monarchy (ſee SAXONS) had continued for more than ſix hundred years: during which, as we ſhall hereafter ſee, they enforced many of their own laws and cuſtoms, though they readily adopted others congenial to the country; and which were derived, as well from the Romans, as the ancient Britons, and which they found in the iſland upon their invaſion of it. The habits and manners of this race were melted down and amalgamated with thoſe of Norman inſtitutions. Every thing was changed; the laws in ſome reſpects were improved, but there was ſtill little taſte for literature and ſcience. From this period, however, we are to date the commencement of certain inſtitutions which, though they required centuries to ripen into maturity, have nevertheleſs given this country a ſuperiority over every other in the civilized world. The variety of diſpoſitions of ſeveral foreign countries being imported into our iſland, at length blended into one national character, celebrated for its courage, its love of freedom, and its pride.

Immediately after the victory of Haſtings, the conqueror marched towards London, carrying before him a ſtandard which had been bleſſed by the pope; and to this the clergy, as is uſual, haſtily reſorted. The biſhops and magiſtrates came out to meet him, and offered him the crown, which he had won by his intrigues and valour. They ſtipulated terms to which he readily acceded, being deſirous of a ſovereignty by the free choice of the people rather than as claimed by the power of the ſword. Though he knew himſelf to be their conqueror, he deſired to be thought their lawful king. William felt that he had power to enforce obedience, but affecting the voice of the people, they imputed his elevation to their own generoſity; and when they felt themſelves oppreſſed or aggrieved, did not ſcruple to reſiſt his power by open revolt and inſurrection. The Engliſh hated the Normans, and were jealous of the power which they ſuſtained in the new government; they envied the wealth which went to enrich thoſe who were truly denominated adventurers in a foreign land, and which was raiſed by loading the natives with heavy taxes, that in thoſe times were with difficulty ſuſtained. At length William ſaw he muſt act with energy if he meant to reign, and from this time he ſeems to have regarded England rather as a conqueſt, than a juſtly acquired dominion. He deprived the biſhops of all judgment in civil cauſes, a right which they had aſſumed during the Saxon ſucceſſion. He reſtrained the clergy to the exerciſe of their eccleſiaſtical power, and he endeavoured to aboliſh trials by ordeal and camp fight. See CAMP-*fight*, and ORDEAL.

We do not intend to recount the acts of the kings of England in this article, but ſhall rather give a general ſketch of the changes and revolutions in the conſtitution, government, manners, &c. of England. The changes introduced by the Norman conqueſt were not very material to the intereſts of the people. Thoſe who occupied the loweſt ranks, ſtill continued in a ſtate of ſlavery; and their numbers were rather increaſed than diminiſhed. The conquerors treated their ſlaves with ſo much ſeverity, that a contemporary writer declined to give a deſcription of it, leſt its inhuman cruelty ſhould appear incredible to poſterity. As the children of ſlaves were alſo ſlaves, this order of the people would have increaſed exceedingly, if many of them had not from time to time obtained their freedom, either by fidelity, or uncommon acts of diligence. In ſome caſes the clergy had the power of granting freedom to ſlaves, and ſometimes the office was performed voluntarily by penitents, who hoped thereby to obtain the pardon of their ſins. The middle ranks in ſociety, that filled up the interval between the freedmen and the barons, were compoſed of different bodies of men, from whom, in proceſs of time, the yeomanry and many of the gentry of England are deſcended. The inhabitants of towns and cities were generally of this middle rank. The barons were a numerous, opulent, and powerful body of men, and comprehended all the conſiderable proprietors of land in England. The acceſſion of the Normans produced many important changes in the political circumſtances of the people—in the tenures by which they held their lands—the ſervices to which they were ſubjected—the magiſtrates by whom they were governed—the courts in which they were judged,—and the laws they were obliged to obey. Theſe changes were chiefly owing to the eſtabliſhment of the *feudal ſyſtem* (which ſee) of police and government in England, by William, in the ſame ſtate of maturity to which it had then attained in his dominions on the continent.

As the moſt important changes in the Engliſh conſtitution were made either in the reign of John, by the limitation of the ſeverities of that ſyſtem, it will not be neceſſary to dwell on the intermediate reigns. The ſucceſſion of the crown of England, after the death of Edward the Confeſſor, became ſo unſettled, that it ſeemed to be the object of ambition to every bold invader, who poſſeſſed the ſlighteſt pretence, together with power and courage, to ſeize the glittering prize. The ſecond William, Henry, and Stephen, are regarded as uſurpers, and did, at the time, reign with a diſputed title. This was a fortunate circumſtance to the natives and their poſterity, as it contributed not a little to raiſe them from that inſignificancy into which they had been depreſſed, to the preſervation of what was left, and to the reſtoration of what had been loſt of their ancient liberties. For the Norman barons, having eſtates both in Normandy and England, were anxious that the ducal and royal crown ſhould reſt on the ſame head, that they might enjoy their eſtates in both countries. Many of theſe barons therefore favoured the pretenſions of Robert duke of Normandy, eldeſt ſon of William I., to the crown of England. This obliged his opponents William and Henry to have recourſe to the native Engliſh, who were ſtill formidable by their numbers, after all the loſſes which they had ſuſtained. Hence they felt their own importance in the ſcale of being, and obtained for themſelves certain rights and immunities which their ſovereigns were ill diſpoſed to grant of their own free will. Henry I. granted them a charter, which proved a model on which the famous charter of liberties in the reign of John was formed. He alſo promulgated a ſyſtem of laws conſiſting chiefly of thoſe of Edward the Confeſſor. Stephen, as his title to the throne was more diſputed, was more liberal of his promiſes; but as he was leſs diſpoſed to perform what he had bound himſelf to do, his whole reign was a ſcene of contention and civil war. At this period the civil law was brought into England from Rome, but not without conſiderable oppoſition on the part of the people, who were ſo much enraged againſt it, that whenever they met with a copy of the Roman law, they deſtroyed it with every mark of indignation. Henry II. conciliated the affections of his ſubjects by granting them a charter, confirming that of his grandfather Henry I. To this prince, whoſe reign was protracted to a great length, the country was indebted for many improvements in the law, as well in its adminiſtration, as in the forms and practice of the courts. At this period the clergy, who were ſcreened from puniſhment on account of their profeſſion, committed every ſpecies of crime, which led (A. D. 1164,) to the enactment of the celebrated conſtitutions which had the effect of reducing the clergy to the rank of ſubjects. Still, however, juſtice was not always adminiſtered in thoſe ancient times with wiſdom and impartiality, partly owing to the ignorance of the judges, and partly to the prevalence of faction among the ſuitors of the courts. Nor was it an eaſy matter to procure relief from an iniquitous ſentence pronounced by a baron or ſheriff, on account of the great diſtance and unſettled ſtate of the king's court, which conſtantly attended his perſon. To remedy this inconvenience Henry II. with the advice of a great council of his prelates, earls and barons, at Northampton, A.D. 1176, divided the whole kingdom into ſix circuits, and appointed three judges to hold courts in each of theſe, by a commiſſion from the king, impowering them to hear and determine all cauſes not exceeding the value of one half of a knight's fee, unleſs the matter was of ſuch importance or difficulty as to require the judgment of the king's court in the royal preſence. Theſe itinerant juſtices took an oath to adminiſter juſtice to all perſons with impartiality. They had alſo authority to judge in all criminal cauſes and pleas of the crown, and to tranſact a variety of other affairs for the public good. Under the reign of Richard, beſides laws relating to the voyage of his fleet to the Holy Land, and thoſe connected with commerce, were others of an excellent nature, in which he attempted to eſtabliſh an uniformity of weights and meaſures over the whole kingdom, a thing greatly wanted, but which has not even yet been accompliſhed. The changes introduced by John have been recited under the article CONSTITUTION. The barons, who procured the famous charter, have been viewed as acting in two capacities, 1, as military vaſſals of the crown: 2, as ſubjects of the kingdom. They conſulted their own intereſt in the firſt capacity, by the limitations of the rigours of the feudal tenures which they procured, and in which all who held lands by military ſervices ſhared with them. They conſulted their intereſt in the ſecond capacity, by the amendments which they procured in the general police of the kingdom, in which all their fellow ſubjects were partakers. Theſe amendments tended to remove or alleviate the ſeveral grievances of which the people in general complained; of theſe, the greateſt and moſt important was, that the mere will and command of the ſovereign were ſubſtituted in the place of law, and men were ſeized, impriſoned, ſtripped of their eſtates, outlawed, baniſhed, and even deſtroyed, without the form of trial. Next to the ſubſtitution of arbitrary will in place of law, was the king's perſonal interference in law-ſuits depending before his courts, in order to interrupt or pervert the regular courſe of juſtice. Theſe flagrant outrages at length wrought their own cure, and thoſe who had tyrannized over the people were obliged to ſubmit to their power.

The common, as well as the ſtatute law of England, received conſiderable improvements in the reign of Henry III.; but his ſucceſſor Edward I. was, as a general and legiſlator, equalled by few of the kings of England, and ſurpaſſed by none. He was ſatisfied with a moderate degree of power, and only laboured to render himſelf terrible to his enemies. The Engliſh, now incorporated with their fierce Norman conquerors, were no longer the tame conſenting people they formerly appeared, but were always prepared to reaſon with that authority which could not eaſily be reſiſted. This ſpirit of oppoſition was tinctured with cruelty: regardleſs of their own lives, the people did not ſeem very ſolicitous about the lives of others. Penal laws began to aſſume more rigour: in the times of William the Conqueror, it was a law, that no man ſhould be puniſhed with death; in the reign of Edward, that law was entirely laid aſide, and ſeveral crimes were rendered capital. But what gave permanence to the reputation of this monarch, was the degree of power the people began to aſſume during this period. The clergy and barons he regarded as rivals; and to weaken their force, he gave authority to the commons: a law was enacted, by which no tax could be levied without their conſent. On account of the many wiſe laws made in this reign, the monarch has been ſtyled the Engliſh Juſtinian. Some of theſe ſtatutes reſpected the church, and were intended to ſet bounds to the power of the pope, the riches of the clergy, and the encroachments of the ſpiritual courts. Others were calculated for explaining, confirming, and enlarging the liberties which had been granted by the great charter. According to ſir Matthew Hale, "the model of the common law, eſpecially in relation to the adminiſtration of common juſtice between party and party, as it was rectified by this king, ſo in a great meaſure it has continued the ſame in all ſucceeding ages to this day; ſo that the mark or epocha we are to take for the true ſtating of the law of England, what it is, is to be conſidered, ſtated, and eſtimated, from what it was when this king left it. Before his time it was in a great meaſure rude and unpoliſhed, in compariſon of what it was thus poliſhed and ordered by him, ſo hath it ſtood hitherto, without any great or conſiderable alteration." Edward made great efforts to reduce the whole iſland of Britain into one kingdom, governed by the ſame ſovereign, and ſubject to the ſame laws; and with reſpect to Wales, he completely ſucceeded ſo as to introduce into it many of the Engliſh laws, cuſtoms, courts, and magiſtrates. His efforts to unite Scotland with England finally failed, and they ſerved only to kindle a moſt violent and implacable animoſity between the people of theſe two kingdoms, which gradually rendered their manners, laws, and cuſtoms more diſſimilar than they had been in more ancient and amicable times. In the following reign, the Scots gained a complete victory over the greateſt army ever ſent into their country: but Edward III., the next in order of ſucceſſion, conteſted, with Philip de Valois, his right to the kingdom of France. He therefore made an expedition into that country, and in the celebrated battles of Creſſy and Poictiers, entirely deſtroyed the French army, and carried the monarch captive to England. See EDWARD III.

This wiſe prince never neglected to conſult his parliament in affairs of moment. There are ſtill extant his writs of ſummons to no fewer than ſeventy parliaments and great councils. The diſtinction between theſe aſſemblies was this; when he deſired only the advice and aſſiſtance of his great barons who ſtill poſſeſſed the greateſt part of the power and property of the kingdom, he called the great council, conſiſting of all the great men, both of the clergy and laity, who held of the crown by barony, and were entitled to a particular ſummons. When he ſtood in need of the counſel and aid of all his ſubjects, he called a full parliament, which conſiſted not only of the barons ſpiritual and temporal, but alſo of the repreſentatives of the inferior clergy,—of the ſmaller barons, or freeholders,—and of the citizens and burgeſſes of the kingdom; and thoſe repreſentatives of the clergy and laity, below the rank of barons, were called the ſpiritual and temporal commons.

Richard II. came to the crown a minor, and by his heroiſm in cruſhing the rebellion of Wat Tyler excited conſiderable expectation, which was completely diſappointed by all the ſubſequent acts of his life. He ſubmitted himſelf to evil counſellors, who took poſſeſſion of his mind, and by their advice he ſacrificed his beſt and ableſt friends, and endeavoured to render himſelf deſpotic. But he was overpowered, ſubdued, and obliged to reſign his crown in favour of his couſin Henry duke of Lancaſter; and this was the commencement of thoſe conteſts between the houſes of York and Lancaſter, which for ſeveral years after deluged the kingdom with blood, and which nevertheleſs contributed in no ſmall degree to give ſtrength and conſiſtency to the conſtitution. In the reign of Richard, Wickliffe began the great work of reformation. The depoſed monarch was murdered with a pole-ax in Pontefract caſtle in the 34th year of his age, having reigned 22 years. His ſucceſſor, Henry IV. ſurnamed Bolingbroke, had to contend with much internal trouble, and had ſo little claim to the ſovereignty which he aſſumed, that conſpiracies were ſpeedily formed againſt him; theſe, however, were quelled and the leaders of them were executed. "If," ſays a good writer, "we compare the times at this period of our hiſtory with thoſe of king John, or thoſe of ſome reigns before him, we ſhall find a great change with reſpect to the inſurgent barons. In the former period they made frequent inſurrections, were often taken in open rebellion, and as frequently pardoned: but in this period they were ſeldom taken without ſuffering the utmoſt rigour of the law. This plainly ſhews how much the power of the barons was ſunk in the courſe of a couple of centuries. This revolution of power is, notwithſtanding, natural and obvious: as the people began to ſhare the government with the nobles, the king was fixed upon as a third perſon to ſecure the balance, and both were contented to make him great from a jealouſy of each other. Noblemen were therefore now executed, not as petty monarchs, but offending ſubjects, and none but kings were conſidered as exempt from penal laws."

In this reign the ſuppreſſion of one rebellion ſeemed only to make way for another more formidable than the former, and more extenſive in its conſequences. The calamities of this period were not, however, confined to internal factions excited by diſcontented barons: the country was threatened with foreign invaſions, and the clergy added not a little to the diſturbance of the public peace. Ever ſince Wickliffe had publiſhed his opinions, his doctrine had been gaining ground, and the clergy were in dread of its prevailing to the excluſion of their ſyſtem and to the ruin of their emoluments. Henry joined the clergy, conſidering that they might be made a powerful engine in eſtabliſhing his uſurped throne, and he recommended the parliament to the care of the church. At firſt the houſe of commons ſeemed reluctant in drawing the ſword of perſecution; they had not, however, vigour ſufficient to oppoſe the power of the court and the clamours of the prieſts, but became inſtruments in their hands for the perpetration of much miſchief. An act was paſſed for burning obſtinate heretics; and William Sawfre, a follower of Wickliffe, was, by virtue of the king's writ, delivered to the mayor of London, and burned alive. This was the firſt martyr in England, on account of religion; but the fires, being once lighted, were not ſuffered to be extinguiſhed. The clergy, under a maſk of hypocriſy, and pretending a regard to truth, took every means that cruelty could ſuggeſt of eſtabliſhing that degree of temporal power, which they had poſſeſſed three centuries before. They ſucceeded, but with this ſtriking difference, that, as in the times of the Saxon heptarchy, their power was founded in the love of the people, in the preſent caſe it had its origin in, and was wholly maintained by, their fears. By theſe means, Henry ſurmounted all his troubles, and the kingdom enjoyed tranquillity. Towards the cloſe of life he determined to embark upon an expedition to Jeruſalem, as well to expiate, as he imagined, the ſins of former years, as to induce his maker to protract the term of his life. His increaſing infirmities prevented him from executing his plan; and in his 46th year he reſigned, by death, his crown to his ſon Henry V. During this reign, if allowance be made for the rancour of the prieſts, to whom the king was too ſubſervient, the government may be ſaid to have aſſumed a form and liberty; the diſtinction between the nobility and the people was rendered leſs conſiderable, and the magiſtrates were leſs arbitrary and leſs venal.

Henry V. was the great hero of his age, and the courage which he had manifeſted from his earlieſt years laid claim to the eſteem and affection of the people over whom he was deſtined to reign. At this period, courage in the great was regarded as almoſt the only virtue: courage and ſuperſtition then made up the whole ſyſtem of human duty. The clergy, notwithſtanding their revenues, paid very little attention to the morals of the people, and were, if poſſible, leſs ſolicitous about their own character: the vices in which they openly indulged, and the paſſions to which they gave free reins, drew upon them a juſt degree of contempt; of which they avenged themſelves, by having recourſe to the engine of perſecution. In this they were encouraged by the king, who, by not oppoſing, may be regarded as a participator of their crimes. One of the early acts of this reign was an attempt to ſuppreſs the doctrines of Wickliffe; and John Oldcaſtle, baron Cobham, was the principal ſufferer in their defence. This excellent man was doomed to bear the moſt excruciating torments: he was hung up by the middle with a chain, and by a ſlow fire literally roaſted alive. The deed was ſcarcely perpetrated when the king, probably diſguſted with the cruelty that had been perpetrated by his ſanction and authority, reſolved to take advantage of the troubles exiſting in France to make a conqueſt of that country. Thither he led a very large army, with which he defeated and almoſt wholly deſtroyed one ſix times larger than his own: he immediately advanced into the heart of the country, making himſelf maſter of many towns. At length he married Catherine, daughter of the French king, and acquired thereby the adminiſtration of affairs in that kingdom, during the life of his father-in-law, fully expecting to be appointed his ſucceſſor. But his death, in the year 1422, fruſtrated his own and the nation's hopes. His ſon, an infant, was afterwards declared king of France and England; but, poſſeſſing none of his father's heroiſm, he ſoon loſt in France all that Henry V. had acquired. The triumphs in France produced ſcarcely any advantages at home. As the Engliſh grew more warlike, they became more brutal; and in their eagerneſs after foreign poſſeſſions, they neglected the cultivation and improvement of thoſe at home. The language became more barbarous. Chaucer and others, about a century before, ſeemed to have drawn it from obſcurity, and enriched it with new terms and combinations; but at this period it relapſed into its former groſſneſs.

The reign of Henry VI. witneſſed much bloodſhed, owing to the rival families of York and Lancaſter. Theſe calamities did not ſubſide till the reign of Henry VII., who was himſelf of the houſe of Lancaſter, and married the daughter of Edward IV. of the houſe of York, when an end was put to the diſſenſions between the different factions of the white and red roſe. In the famous battle that fixed Edward IV. on the throne of England, it is ſaid that 40,000 men were left dead in the field. In this dreadful conteſt, each party, as it happened to be victorious, called in the executioner to complete the bloody tragedy begun in the field. In the reign of Henry VI. the art of printing was firſt practiſed in England by William Caxton. He tranſlated ſome French works, which he printed; and, by his new art, gave currency and celebrity to the tranſlations of others. The prieſts at this period poſſeſſed no ſmall ſhare of erudition, as is evident from ſome Latin productions ſtill extant; but learning was ſeparated from the purpoſes of common life, and though not neglected by the clergy, yet it deſcended no lower, the people at large not conſidering it as any concern of theirs.

The wars in which Edward IV. engaged were long and bloody; and, upon a ſuſpenſion of arms at home, he proclaimed war with France, which he knew would gratify his ſubjects, who have been, at almoſt every period of their hiſtory, more fond of ſplendid than uſeful acquiſitions. To proſecute this ſcheme, he ſent to his ally, the duke of Burgundy, a reinforcement of 8000 men; and ſoon after followed himſelf, at the head of a very numerous army. The French king was alarmed at this formidable invaſion, and feeling that he was unable to contend with his antagoniſt, he had recourſe to treaty; and for a ſtipulated ſum, Edward agreed to lead back his forces to England. Towards the cloſe of life he indulged the hope of invading France again: his parliament conſented, and in that aſſembly of the nation the project was unanimouſly declared to be juſt and neceſſary. The people ſeemed pleaſed with the proſpect, and great preparations were made for the expedition, when, fortunately for the intereſts of humanity, Edward died after a reign of little more than 22 years.

Edward V. ſucceeded, as we have ſeen, (ſee Edward,) to the kingdom in name, but not in fact: for, long before he was capable of acting for himſelf, he was depoſed and murdered at the inſtigation of his uncle, the duke of Glouceſter, who ſecured to himſelf the crown under the title of Richard III. The infamy of this prince's character has been fully deſcribed by every hiſtorian of authority. As he obtained the government by treachery and murder, ſo he loſt his life in ſupport of what he had unlawfully gained. At the battle of Boſworth Richard had to contend with Henry, earl of Richmond, who was not only completely victorious, but was proclaimed king by the unanimous voice of the army, on the very ſpot in which the cruel Richard was ſlain. By the death of this king, the Plantagenet race, which had been in poſſeſſion of the throne more than 300 years, became extinct. With him alſo terminated the conteſts between the houſes of York and Lancaſter, in which, in the courſe of about 30 years, an hundred thouſand lives were loſt either in battle or by the hands of the executioner. Theſe diſſenſions had reduced the kingdom to a ſtate of almoſt ſavage barbarity: laws, arts, and commerce were entirely neglected; every thing laudable gave place to the practice of arms. The people had attained no ideas of pacific government, nor could they applaud or juſtify thoſe who cultivated it. In their wars, it is recorded to their credit, that the women, however formidable and active, were exempted from capital puniſhment, unleſs accuſed of the undefined and undefinable crime of witchcraft. The clergy were diſtinct from the laity in cuſtoms, conſtitutions, and learning: they were governed by the common law, which was delivered to them by the traditions of their anceſtors. As a body, they did not intereſt themſelves in the civil polity; and were not diſpleaſed to ſee the laity, whom they did not deign to regard as fellow-ſubjects, but rivals for power, weakening themſelves by continual conteſts: the laity, on the other hand, regarded the clergy with blind veneration, which leſſened their reſpect and attachment to the monarch on the throne. There was little virtue among individuals of the nation, and the government was ſubject to diſorders of the moſt fatal kind, which perpetually produced all the horrors of civil war.

With the reign of Henry VII. we commence a new era in the hiſtory of our country. Under his ſway we behold one of the greateſt revolutions that was ever effected by the prudence and perſeverance of one great prince: a nation of tumult reduced to civil ſubordination; a haughty ariſtocracy humbled; wiſe laws enacted; commerce reſtored; and the arts of peace cultivated and encouraged by a people, to whom before, war only was delightful. The whole government put on a new form, and Henry was one of the moſt uſeful monarchs that ever held the ſceptre of theſe kingdoms.

The firſt care of Henry was to unite the intereſts of the houſes of Lancaſter and York, by marrying Elizabeth, the daughter of Edward IV. His reign began very auſpiciouſly by a ſtrict obedience to the laws, which he ever after enforced with firmneſs and dignity. Before his reign it had been uſual to take away the lives of thoſe attainted of treaſon; but Henry thought it ſufficient, in moſt caſes, to deprive thoſe taken in arms of their fortune and eſtates, which he applied to his own uſe. By theſe means he deprived his enemies of the power of injuring him; and he was enabled, by new acceſſions of wealth, to perform many acts of liberality. He is ſaid to have releaſed all priſoners for debt in his dominions, whoſe debts did not amount to forty ſhillings, and paid the creditors their whole demand from his own coffers. He has been accuſed of avarice, but it is doubtful whether his conduct in this reſpect does not rather merit the applauſe of uſeful economy. His government was diſturbed by attempts at ſetting on the throne Lambert Simnel, as earl of Warwick; and afterwards by a ſimilar attempt with regard to Perkin Warbeck. In the year 1499 he freed himſelf from theſe conſpiracies, by the conviction and execution of Perkin and the feigned earl of Warwick. After this, the reign of Henry was truly reſpectable: his government was formidable to his own ſubjects, and claimed the reſpect of rival potentates. He paid much attention to the wants of the lower claſſes, and was anxious to depreſs in the ſcale of power the nobility and clergy. From theſe moſt of the calamities of former reigns had reſulted; and on that account he contrived means to leſſen their authority in the ſtate. He allowed the nobility, by a law paſſed in his reign, to alienate their eſtates; and he diminiſhed, as far as he was able, the privileges claimed by the clergy as their right. He was, at the ſame time, a friend to the people, who in former periods were the ſure victims of powerful ambition and revenge. They, in all caſes, were the ſufferers, on whatever ſide they fought, if they had the misfortune to loſe the victory. To remedy this, in a great degree, Henry procured the paſſing of an act, by which it was eſtabliſhed that no perſon ſhould be impeached or attainted for aſſiſting the king for the time being. This wiſe ſtatute ſerved to repreſs the deſire of civil war, as multitudes would naturally take arms in defence of that ſide on which they were ſure of loſing nothing by defeat, and their numbers would intimidate inſurgents. But the greateſt efforts of this king were directed to promote trade and commerce, which naturally introduced a ſpirit of liberty among the people, and diſengaged them from their dependence on the nobility. Before this era, the towns owed their original to ſome ſtrong caſtle in the neighbourhood, where the great lord generally reſided, maintaining at his expence a very large retinue, who, as dependents on his bounty, were on all occaſions bound to vindicate his cauſe. The number of theſe drew together, in or near the ſame place, artificers, victuallers, and ſhop-keepers, to furniſh the lord and his attendants with the neceſſaries of which they ſtood in need. It was the wiſe policy of Henry to bring the towns from ſuch a neighbourhood, by inviting the inhabitants to a more commercial ſituation. He attempted to teach them frugality and the payment of debts; the life of induſtry, by his own example; and never omitted to include the rights and principles of commerce, in all his treaties with foreign princes.

At this period the continent, as well as the Britiſh iſles, ſeemed to be making great advances to improvement. The ſovereigns of Sweden, France, and Spain, were the encouragers and protectors of the riſing arts. The Portugueſe had ſailed round the Cape of Good Hope, and Columbus had juſt made the diſcovery of a new world. Henry was deſirous of following the example ſet him, and granted to certain enterprizing merchants to go in queſt of new countries. By theſe and ſimilar exertions the king ſaw his country civilized, the people pay their taxes without inſurrection; the nobility learning a juſt ſubordination, the laws alone ſuffered to inflict puniſhment, towns begun to ſeparate from the caſtles of the nobility; commerce every day increaſed, and the ſpirit of faction was in a great meaſure extinguiſhed. He was at peace with all the world, and having iſſued a general pardon to his own ſubjects, he had reaſon to expect the happineſs to which wiſe meaſures and true patriotiſm are juſtly entitled; when, at the age of 52, he died of the gout in his ſtomach. In ſome reſpects he has been regarded as the ſecond Alfred, a title to which he has a good claim, on account of the great changes which he introduced in his kingdom;—changes which had the moſt favourable tendency to effect the improvement and happineſs of his ſubjects.

Henry VIII., the ſon to the late king, aſſumed the reins of power under the moſt fortunate auſpices. He found himſelf in poſſeſſion of a peaceable and flouriſhing kingdom; prudent miniſters, who knew the wants of the people, and were ready to provide for them; and a well-ſtored treaſury. The young king, however, made but an ill uſe of the bounties of providence, with which he was ſo abundantly ſurrounded. He had been diligently inſtructed in all the learning of the times; but his ſtock of knowledge ſerved only to inflame his pride, and not to control his vicious affections. The love of his ſubjects was teſtified by an adulation, which produced the moſt miſchievous effects. His vaſt wealth, inſtead of relieving his ſubjects, or of increaſing the national honour, only contributed to ſupply his debaucheries, or gratify the rapacity of the miniſters of his pleaſure. The acts of his life will come more properly under the article devoted to his name. In this place it will be ſufficient to obſerve, that he was perpetually falling from one extreme to another, and agitated by contrary paſſions; it became doubtful to his ſubjects in what manner they ſhould act, or what they ſhould believe, ſo as to obtain his approbation. His conduct as a king was marked with the moſt atrocious acts of tyranny; he expected every one to ſubmit to his will, however frequently that will was changed: yet his reign is memorable on account of the great revolution that was achieved in it by the celebrated Luther, for a full account of which we refer to the article Luther. At firſt the king wrote againſt the doctrines avowed by the former; and for his ability and learning, obtained from the pope the title of "Defender of the Faith," a title which has been continued to his ſucceſſors to the preſent time. He afterwards revolted from the Roman church, and required that his ſubjects ſhould acknowledge him, and him only as head of the church of England. The parliament, entirely dependent on the king, ſided with him in his views of ſeparating from the church of Rome, and readily complied with his other meaſures to ſtrengthen the reformation. Henry, who was an artful politician, knowing that his parliament was devoted to his will, made uſe of the opportunity to render himſelf abſolute. He accordingly oppoſed the parliament againſt the monks, and obtained their ſuppreſſion. While parliament was buſy in ſuppreſſing the religious houſes, moſt of which were houſes of infamy, the king was deviſing methods of deſtroying the power of the ſuppreſſors. This was the origin of the unlimited power which he now aſſumed: he had a moſt complying parliament, ready to ſanction not only what he did, which in many inſtances were deeds of the darkeſt hue, but likewiſe what he intended to do. He was not wanting to ſtrengthen his own power, and claimed the ſame obedience to his proclamation as to the acts of the whole legiſlature. No king of England, as will be ſeen hereafter, lived ſo much the terror of his people. Some perſons wielding a ſceptre have been tyrants, from the frequent revolt of their ſubjects; ſome, from being miſled by favourites; and ſome, from a ſpirit of party: but Henry VIII. was cruel, from a diſpoſition which ſeemed prone to inflict miſery on all about him; he was a ſavage in government, in religion, and in his own family: yet ſuch are the inſcrutable diſpenſations of heaven, that while the harmleſs Henry VI. was dethroned, impriſoned, and aſſaſſinated, the preſent tyrant was permitted to die a peaceable and natural death, if we except the ſufferings which a guilty conſcience cannot fail to inflict. Fortunately perhaps for the people, Henry contrived to diſſipate all thoſe treaſures of which his tyranny plundered his ſubjects: he died poor, and tranſmitted the crown to his ſon and ſucceſſor as dependent on the people for their ſupplies in parliament as at any former period. The wanton profuſion of princes is always hurtful to themſelves; but in many inſtances it has been beneficial to their ſubjects, by preventing greater evils. If Henry VIII. had been more frugal, he would probably have been more dangerous.

The character of Edward VI. has, under his own name, been deſcribed. He died at too early an age to act for himſelf; but during his ſhort reign, the principles of the reformation were encouraged; people were allowed to uſe or diſuſe the practice of confeſſion, as they thought fit; images were taken from the churches, prieſts were allowed to marry, the maſs was aboliſhed, and a liturgy was drawn up, which, with very few alterations, has been continued to the preſent times. Such important changes could not be effected without danger: inſurrections were excited in many parts of the kingdom, which were without much difficulty ſuppreſſed, though many were the victims of the unhappy conteſts.

The reign of queen Mary was marked with cruelty and bloodſhed. She reſtored the Roman Catholic religion, and without heſitation burnt, or otherwiſe deſtroyed, all who fearleſsly oppoſed her will, and the will of her infamous miniſters, Bonner and Gardiner. The reign of this ſovereign was fortunately ſhort; yet, in ſomewhat leſs than four years, five eminent and conſcientious prelates, twenty-one miniſters, and more than eight hundred ſubjects of lower rank in life, were conſigned to the flames for maintaining what they believed to be truth: beſides theſe, we have no accurate account of the numbers who died in priſon, by more lingering and more cruel deaths than even the flames of Smithfield could inflict; nor has it been recorded how many, through fear of death, ſacrificed a good conſcience, and thereby endured for the remainder of their lives ſufferings a thouſand times worſe than the death which a tyrant is enabled to order.

Elizabeth, whoſe character and government have been delineated in the laſt volume, reſtored the principles of the reformation, and advanced the kingdom to the higheſt pitch of ſplendour. She had been nurtured in the ſchool of adverſity, and drew from it leſſons of the higheſt importance to her future conduct. While ſecluded from the buſy world in a loneſome priſon, ſhe was employed in the improvement of her mind, and in deviſing methods of reforming the church, ſo ſoon as providence ſhould make way for her government; and one of her earlieſt acts as ſovereign was to eſtabliſh the reformed religion. The people readily ſeconded her deſigns: they perceived the ill uſe which the papiſts had made of their power in the laſt reign; and they were willing to ſuppoſe that the ſavage acts, which had been committed by Mary and her biſhops, were the neceſſary conſequences of the faith which they eſpouſed, and in behalf of which they effected their cruel purpoſes. Elizabeth ſoon aſſembled her parliament, the reformation was finiſhed, and that form of religion was eſtabliſhed which is now deemed the religion of the country. The clergy, in general, ſubſcribed to the new forms: of nearly ten thouſand who were in poſſeſſion of benefices of different degrees of rank and value, ſcarcely more than an hundred choſe to quit the emoluments of their office, rather than abandon the principles to which they had adhered in the laſt reign. "Thus," ſays an hiſtorian, "England changed its belief four times ſince the acceſſion of Henry VIII." Strange that a people, who are ſo reſolute, ſhould be guilty of ſo much inconſiſtency! that the ſame people, who this day publicly burn heretics, ſhould the next not only think them guiltleſs, but conform to their opinions. Elizabeth, though firmly fixed on her throne, had enemies in almoſt all the neighbouring potentates; who endeavoured by every means in their power to excite diſcontent among her own Catholic ſubjects. In this ſituation, ſhe could only rely upon the reſources which proceeded from the affection of her ſubjects, and the wiſdom of her adminiſtration. Her governing maxim was unqueſtionably founded in wiſdom; it conſiſted in acquiring the eſteem and affection of her people. She was an economiſt of the nation's money, and ſparing in her rewards to her favourites. She diſtributed rewards and puniſhments with impartiality; knew when to flatter and when to upbraid; could diſſemble ſubmiſſion and preſerve her prerogatives; ſhe ſtudied the people ſhe was to govern, and not unfrequently flattered their follies in order to ſecure their hearts.

The errors of this ſovereign, and the acts of cruelty to which ſhe gave her ſanction, have been deſcribed in her own life, or in that of archbiſhop Cranmer, or will be found hereafter in the article Mary queen of Scots, or in other parts of this work of minor conſideration; but it muſt be obſerved here, that whatever puniſhments or cruelties were exerciſed in this reign, they moſtly fell upon the great, and in no inſtance were the people more happy internally, or more formidable abroad, than during this period. It will, however, be readily admitted, that it was not owing entirely to the queen that the nation was ſo completely proſperous at this period; the people, as if ſpontaneouſly, began to exert their native powers, and every art, and every genius put forth all their vigour. The Engliſh could not boaſt of new or ſplendid acquiſitions: their influence in foreign courts was extremely limited, but commerce grew up and flouriſhed. The people began to feel the effects of their own exertions, and to underſtand in what conſiſted the independency of a great nation; and England became at once laborious, enterprizing, powerful, and in a degree poliſhed and polite. The ſucceſsful voyages of the Spaniards and Portugueſe excited their emulation: they fitted out ſeveral expeditions with a view of diſcovering a northern paſſage to China, and, though diſappointed in their firſt and principal object, their voyages were not wholly fruitleſs. Our countrymen, Cavendiſh and ſir Francis Drake, circumnavigated the globe, and diſcovered in the proſecution of their voyages a ſkill and proweſs very ſuperior to the moſt experienced navigators of thoſe nations who led the way in nautical diſcovery. Sir Walter Raleigh, without any aſſiſtance from government, colonized New England; and theſe expeditions at length formed one of the moſt powerful marines of Europe, which in a very ſhort time was enabled to oppoſe the fleet of Spain. (See Armada.) The ſuperiority obtained by the Engliſh at ſea, at this period, gave them a ſort of naval ſovereignty which they have ever ſince inviolably preſerved, and which, we truſt, they will very long maintain, notwithſtanding the boaſtful language of the preſent emperor of France. If, for wiſe purpoſes, he muſt ſubject the continent to his power and controul, we truſt that our own iſlands will, by union among the people, be freed from the tyranny which he has for many years been exerciſing among other nations, which have evidently been ſacrificed by their own want of unanimity, and by the miſmanagement of their ſovereigns.

In the reign of Elizabeth, external commerce was not more cultivated than internal manufactures. Flemiſh manufacturers, who had been perſecuted at home, fled to England for an aſylum, which they found, and for which they made ample amends by the arts which they introduced, and the induſtry which was excited by their example, and by the wealth which their labours acquired. In polite arts and in literature the Engliſh excelled all other nations. The reign of Elizabeth has by ſome writers been denominated the Auguſtan age of literature. The diſputes cauſed by the reformation of religion had retarded the progreſs of our language among the powerful, but they excited a ſpirit of enquiry among the middling and lower orders of ſociety. The people began to read, and being allowed to peruſe the bible in their own language, their morals, and perhaps their taſte, rapidly improved. The reformers, who had fled from the perſecutions of Mary, returned to promulgate their doctrines at home, and by a reſidence abroad their language was corrupted by foreign idioms and barbarous phraſes. Theſe archbiſhop Parker ſet himſelf aſſiduouſly to reform, as well by his own excellent example as by precept. He corrected the Engliſh tranſlation of the bible, and printed it with royal magnificence. His own ſtyle poſſeſſed all the eloquence of the times; it was manly and conciſe, but wanted ſmoothneſs.

Such were the leading improvements in Elizabeth's reign; and, ſays a good writer, "if we look through hiſtory and conſider the riſe of kingdoms, we ſhall not find, in all its volumes, ſuch an inſtance of a nation becoming wiſe, powerful, and happy in ſo ſhort a time. The ſource of our felicity may be traced to the reign of Henry VII., and though the ſtream was interrupted by intervening tyrannies, yet, before the end of Elizabeth's life, who was his grand-daughter, the people became the moſt poliſhed and the moſt happy people upon earth. Liberty, it is true, as yet continued to fluctuate: Elizabeth knew her own power, and often ſtretched it to the very limits of deſpotiſm; but when commerce was introduced, liberty neceſſarily entered in its train; for there never was a nation completely commercial, and at the ſame time perfectly deſpotic."

On the death of Elizabeth James VI. of Scotland ſucceeded to the throne of England, with the univerſal approbation of all orders of the ſtate. Elizabeth bequeathed him her crown almoſt with her laſt breath; he was the neareſt in the order of ſucceſſion, and he had all the ſanction which parliament could confer. He began his reign by a laudable attempt to unite both kingdoms into one, which he effected without much difficulty, and from that period the two kingdoms have been governed by one ſovereign. James, though uſed to arbitrary power, ſet himſelf to ſtudy the Engliſh laws, by the authority of which he reſolved to govern. Whether he did not comprehend their full import, or that his habits were too much fixed to ſubmit to the neceſſary changes which his new ſituation required, it would be uſeleſs to enquire; but it is certain that his whole reign was marked with diſputes between him and his parliament. The king was ever attempting to keep the royal ſplendour unſullied; the other aiming at leſſening the dangerous part of the prerogative: the one labouring to preſerve the laws and inſtitutions of former reigns; the other as ſtedfaſt in aſſerting the inherent privileges of mankind. When the parliament refuſed a ſubſidy, the king was deſirous of availing himſelf of the precedents ſet by other monarchs, by extorting a benevolence. The houſe of commons felt their conſequence as the protectors of the people, and remonſtrated againſt every act of arbitrary power, as incompatible with their rights and privileges. Theſe attempts of the crown, and the reſiſtance of the people, continued through the whole reign, and firſt gave riſe to that ſpirit of party which has ever ſubſiſted in England, the one ſide declaring for the king's prerogative, the other for the rights and liberties of the ſubject.

James exhibited much moderation with regard to thoſe who did not think on religious ſubjects as he was accuſtomed to think, and who did not conform to the eſtabliſhed forms of church diſcipline, wiſely judging that men ſhould be puniſhed for evil actions, and not for erroneous opinions. The conſpirators againſt his government, as will be ſeen in his life, were ſeverely puniſhed; but he cultivated the arts of peace, and obtained as a juſt reward the general good will of the nation. It has been aſcribed to this monarch that the Engliſh have attained to a noble freedom of thought, and the dignity of juſtifying their opinions. James neither cultivated nor underſtood foreign negociations or alliances. His reign was marked with none of the ſplendours of triumph, nor with new conqueſts and acquired dominions; but the arts were ſilently advancing in improvement: reaſon was extending her influence, and deſcrying a thouſand errors in religion and government that had been rivetted by long preſcription. The people began to think for themſelves, to eſtimate their rights and conſequence: the reformation had introduced a ſpirit of liberty, even at the time that the conſtitution and the laws were built upon arbitrary power. "James," ſays the hiſtorian, "taught them, by his own example, to argue upon theſe topics: he vindicated the divine right of kings againſt the natural privileges of the people: the ſubject began in the controverſy, and it was ſoon diſcovered that the monarch's was the weakeſt ſide of the queſtion."

Charles I. aſcended the throne in the year 1625, and was extremely popular, as well on account of his own virtues and addreſs, as in reſpect to the fortunate circumſtances in which he was placed. The country was in a peaceable and flouriſhing ſtate: his title to the crown was undiſputed, and he had formed an alliance with one of the moſt powerful monarchs that ever reigned in France, whoſe ſiſter he had married. The pleaſing proſpect was of ſhort continuance; the people had learned to reaſon: they felt their own power, and it was determined in parliament to oppoſe the ancient claims of the crown. Charles had been taught to conſider the royal privileges as ſacred pledges, which it was his duty to defend: his father had implanted the doctrines of hereditary and indefeaſible right early in his mind. James contemplated theſe doctrines in theory, but it was ſoon the fate of Charles to aſſert and defend them by action. He miſtook the genius of the people he had to govern; they had imbibed the principles of liberty; but he wiſhed to act by maxims and precedents that had their origin in times of ignorance and ſlavery. The late king had been forced into breach with Spain, and Charles gave early indications of a deſpotic temper, which rendered the parliament remiſs in furniſhing him with money for carrying on the war. In a ſhort time his favourite Buckingham perſuaded him to take the part of the French Hugonots, in their quarrel with the crown. They were ill ſupported, and the proteſtant intereſt received an irrecoverable blow in France. The blame was attributed by the people and parliament to Buckingham, who was aſſaſſinated by Felton. This the king laid ſeriouſly to heart, though it did not deter him from his arbitrary proceedings. For ſeveral years Charles reigned without aſſembling a parliament, during which he did as he pleaſed, promulgating laws, and impoſing taxes on his ſubjects to the great mortification of thoſe who felt for their liberties as men and Engliſhmen. He laid arbitrary impoſitions upon trade, which many reſiſted: he levied monies upon monopolies of ſalt, ſoap, and other neceſſaries of life. His government became every day more unpopular, and Burton and Prynne wrote againſt the proceedings of the court. They were proſecuted for their writings in the ſtar-chamber in a very arbitrary and cruel manner, and puniſhed with ſo much ſeverity as excited an almoſt univerſal indignation againſt the authors of their ſufferings. The king next made uſe of Laud and Strafford as inſtruments in carrying on his deſpotic meaſures. Theſe he was in a ſhort time obliged to abandon to an ignominous death on the ſcaffold. Charles, in the early part of his reign, had paſſed the petition of rights into a law, which was intended by parliament for the future ſecurity of the liberty of the ſubject, by which it was enacted "that no man hereafter ſhould be compelled to make any gift, loan, benevolence, tax, &c. without common conſent of parliament." This principle he perpetually violated till at length a civil war broke out. Notwithſtanding the many acts of tyranny and oppreſſion, of which the king and his miniſters had been guilty, yet multitudes ſided with the court and joined the ſtandard of Charles. Many of the nobility and gentry were attached to the crown, and conſidered their own honours as connected with it, and no inconſiderable part of the landed intereſt joined the king. The parliament claimed for themſelves the executive power, and were favoured by moſt of the trading towns and corporations; but its great reſource lay in London. The firſt battle was fought at Edge-hill, in Warwickſhire, in which the royaliſts were ſo far triumphant that parliament was obliged to invite the aſſiſtance of the Scots, who entered England with 20,000 horſe and foot. From this period war was carried on with various ſucceſs, till at length the king was overpowered, reduced, impriſoned, tried, and finally beheaded. The character of this prince will be found under the article CHARLES I. With the death of the king, the miſeries of civil war terminated, and the parliament, which was triumphant, had now no enemy to fear, except thoſe very troops which hitherto had been inſtruments in their hands, in achieving their deſigns. At firſt they hoped to diſband the troops; but Cromwell, who was the rival power in the ſtate, had other projects to accompliſh. He had already rendered the army in a great meaſure independent of the parliament; and now formed a council of officers, and another of common ſoldiers, called agitators, who were appointed to enquire into the grievances of the military, and lay them before parliament. As the commons, from neceſſity, granted their requeſts, the army roſe in their demands, till at length the parliament enjoyed but the ſhadow of authority. It, however, paſſed an act, making it high treaſon to acknowledge Charles Stewart, ſon of the deceaſed king, as ſucceſſor to the throne. They likewiſe voted the houſe of lords uſeleſs and dangerous, and paſſed an act for the abolition of all kingly power. A great ſeal was made, on one ſide of which were engraved the arms of England and Ireland, and on the reverſe was repreſented the houſe of commons ſitting, with the motto, "The firſt year of freedom, by God's bleſſing reſtored 1648." No meaſure was omitted that could probably eſtabliſh the power of the uſurper, and exclude for ever the kingly power in England. Much was done for retrieving the glory of England at ſea. Cromwell and Ireton excited the jealouſy of the republicans, who contrived firſt to employ them in the reduction of Ireland, and afterwards againſt the Scots, who had acknowledged and received Charles II. as their king. Almoſt immediately, by the moſt unparalleled exertions, a fleet was produced ſuperior to any that had ever been ſeen in Europe. An act of navigation was paſſed, and war was declared againſt the Dutch, who were till then regarded as invincible at ſea. Cromwell, from his ſucceſſes in Scotland, found little difficulty in obtaining the honour of being declared commander in chief of the Engliſh army. Admiral Blake, and other naval commanders, carried the terror of the Engliſh name by ſea to all quarters of the globe, and Cromwell, having little employment, began to think how he might eſtabliſh his own authority paramount to that of the ſtate. On the 20th of April 1653, at the head of 300 muſqueteers, he diſſolved the parliament, opprobriouſly driving the members, about one hundred in number, out of their houſe. He next annihilated the council of ſtate, with which the executive power was lodged, and transferred the adminiſtration of government to about 140 perſons, whom he ſummoned to Whitehall on the 4th of July 1653. After this he was declared lord protector; which, however, did not comport with his ambitious views; he was deſirous of the name, as well as the power of king, to which he could never arrive; and in September 1658, he died after an uſurpation of nearly five years. See CROMWELL.

From Charles's death in 1648, to the deceaſe of Cromwell in 1658, England was unqueſtionably improved equally in riches and power; beſides the introduction of the navigation act, which was eſtabliſhed in the reign of Charles II. and which has been regarded as the palladium of Engliſh trade; monopolies of all kinds were aboliſhed, and liberty of conſcience to all ſects was granted, which was highly advantageous to the population and manufactures of the country. Under Cromwell, the arts, ſciences, and literature were not much encouraged, yet he did many things worthy of praiſe; and as his genius and capacity led him to the choice of fit perſons for the ſeveral parts of adminiſtration, ſo he paid ſome regard to men of learning, and particularly to thoſe entruſted with the care of youth at the univerſities. Richard, his ſucceſſor, poſſeſſed none of the talents for buſineſs, nor indeed any activity of diſpoſition, for which his late brother was ſo celebrated, and was in a very ſhort time driven, without reſiſtance, into that obſcurity for which his temper was better adapted, than for the buſineſs of government. The reſignation of his power made way for

Charles II. who returned to the throne of his father by the general concurrence of the people; this was in the year 1660, and for ſome time he ſeemed deſirous of promoting the people's happineſs, though he did not forget to avenge himſelf on the enemies of the late king; the bodies of Cromwell, Ireton, and Bradſhaw were taken from the tomb, and treated with every indignity. Of thoſe who ſat in judgment on Charles I. ſome were dead, others had left the country, and ſome the reigning prince thought deſerving of mercy, but ten were devoted to almoſt immediate deſtruction. Theſe bore their ſufferings with the conſtancy of martyrs dying in a good cauſe, thanking heaven in the extreme of their torments, that they were allowed to be witneſſes of the truth. It was now to be feared that the tide of loyalty would bear away in its courſe all the former mounds of freedom. Parliament ſeemed to concur in all the deſigns of the court, and even to anticipate its wiſhes; but the monarch was by no means attentive to thoſe who had followed him in his misfortunes; his pleaſures and his flatteries engroſſed all his cares, and exhauſted his finances, ſo that he had nothing left, and, apparently, no wiſh to pay the debt of gratitude. From thoſe who would willingly have expoſtulated with him on his miſconduct, he fled, and endeavoured to forget every kind of ſerious buſineſs in ſcenes of mirth, riot, and debauchery. By his own example, he undermined the principles of religion, and the nation, prone to extremes, exhibited every ſpecies of licentiouſneſs, which was practiſed in the moſt diſſolute court that ever exiſted in England. Charles II. though without a pretence to religion, permitted the perſecution of ſectaries, which excited among thoſe, who were objects of it, a plan for a general inſurrection. The plot was diſcovered, and the conſpirators were taken and executed. This circumſtance afforded a pretext for continuing the parliament then ſitting; and repealing the act for triennial parliaments, as being dangerous in times of commotion. This parliament was ſo completely ſubſervient to the will of the king, that he might, with activity, have become abſolute. They confirmed the infamous doctrine of paſſive obedience by a ſolemn act, and aſſigned the king a revenue of twelve hundred thouſand pounds, a ſum which none of his predeceſſors had ever poſſeſſed; nevertheleſs his prodigality rendered him indigent, and inſtead of deſiring an aſcendancy over his parliament, he was content to be a perpetual dependent on their bounty. His prodigality and libertiniſm ſoon alienated the affections of his ſubjects, which in the ſhort period of two years were changed to a contempt of his perſon and adminiſtration. The war, in which he engaged with the Dutch, was unattended with any brilliant ſucceſs, and the enemy's attempting to ſail up the river Thames excited clamours againſt the government. The people began to compare the preſent ſtate of things with the meaſures and adminiſtration of Cromwell; in the one caſe they enjoyed ſecurity at home, and claimed the higheſt reſpect from ſurrounding nations; in the other every principle, private and public, was forced to give way to the paſſions of the ſovereign, which he was determined to gratify at any expence. Uniformity in religion became the popular cry, and, in 1673, the teſt act was paſſed, obliging every perſon in or under government, not only to take the oaths of allegiance and ſupremacy, but receive the ſacrament of the Lord's-ſupper in ſome pariſh church, before competent witneſſes, and ſubſcribe a declaration renouncing the doctrine of tranſubſtantiation. This was levelled againſt the duke of York, the king's brother, who was an avowed papiſt, and whom the parliament wiſhed to exclude from the throne. The fears and diſcontents of the nation were vented without reſtraint, which gave great offence to the court. A great degree of ſeverity was exerciſed againſt the nonconformiſts to epiſcopacy, and every means taken that was likely to repreſs the riſing ſpirit of the country. It was known or violently ſuſpected that Charles was a penſioner on the court of France, his parliament in 1677, addreſſed him to make war upon that country, which he refuſed. The people became exaſperated againſt almoſt all public meaſures; the king was alarmed with the proſpect of a civil war, and made conſiderable conceſſions to avoid the odium which his paſt conduct had juſtly incurred. Many of the leading members of parliament had however determined on ſuch a change as ſhould exclude the duke of York from the crown. To forward this the famous plot of Titus Oates was contrived, which charged the papiſts with a deſign of murdering the king, and of introducing popery by means of the Jeſuits, as the eſtabliſhed religion of the country. Several reſpectable perſons were tried and convicted, principally on the evidence of Oates, who was unworthy of credit. A bill was brought into parliament to exclude the duke from the throne, which was paſſed in the commons, but was thrown out in the houſe of lords. A plot was now invented on the other ſide, in which the principal proteſtants were accuſed of an endeavour to deſtroy the king. For this, on the evidence of lord Howard, a man of infamous character, lord Ruſſel, who had been zealous in his oppoſition to the popiſh ſucceſſion, Algernon Sidney, and other diſtinguiſhed characters, were tried and executed. The terror which the meaſure carried with it intimidated the beſt friends to their country; it ſilenced the oppoſition of the city of London and other corporations, and the duke of York triumphed in the victory which had been obtained by perjury. From this period the reign of Charles was as abſolute as that of any monarch in Chriſtendom, but the ſpirit of freedom, which the people had imbibed, ſtruggled hard againſt the ſpirit of obedience, which the clergy attempted to inculcate. Another civil war threatened the nation ſtill more dreadful than the former, as the forces were more equally divided; but fortunately for the peace of the country, the king was ſuddenly ſeized with an apoplectic fit, and died in the fifty-fourth year of his age.

Though England, during the reign of the ſecond Charles, was agitated by contending intereſts, yet commerce continued to increaſe; its good effects had been duly appreciated, and multitudes were ready to turn their wealth and induſtry into this courſe. Many new manufactures were introduced, and many old ones brought to perfection. When France, by ſhameful and wicked policy, baniſhed her beſt ſubjects, the proteſtants, England opened her arms to receive them, and with them ſhe received large acceſſions of national wealth. To the afflictions and exile of this monarch we are indebted for many of our beſt vegetables which were introduced by his followers from the continent. Science and literature made rapid progreſs during this reign: Newton and Tillotſon; Burnet and Shaftſbury; Butler and Dryden flouriſhed at this period: the Royal Society was inſtituted, and from this time our countrymen took the lead in every uſeful ſcience, and they have maintained their ſuperiority to the preſent hour. Nor muſt it be forgotten, that if Charles was the firſt of our monarchs who claimed the protection of ſtanding forces, yet to him and his brother we are indebted for ſome very important improvements in the art of ſhip-building, an art which has given us a preponderating balance among the nations of the world, and which, we truſt, will, in the hands of an over-ruling providence, preſerve us from that overwhelming ruin in which almoſt all the empires of the continent are involved.

The oppoſition, which during the late reign had ſhaken the throne, vaniſhed almoſt entirely at the acceſſion of James II. The affection of the people ſeemed to know no bounds when the king, as it were, ſpontaneouſly made a declaration in favour of the church of England. That church, to flatter the prejudices of the preſent and late monarchs, had authoritatively from the pulpit and preſs pronounced all reſiſtance to a reigning ſovereign unlawful: a doctrine which, however pleaſing it might be to the feelings of the king, proved fatal to his peace, and, in the event, drove him from the kingdom. The army and people ſupported him in cruſhing an ill-concerted rebellion of the duke of Monmouth, who pretended to be the lawful ſon and heir of Charles II., and had aſſumed the title of king. The duke was taken and was beheaded; and ſome hundreds of his adherents loſt their lives likewiſe by the inſtrumentality of judge Jeffries and colonel Kirke, names that have been deſervedly handed down to poſterity with every infamy that can attach to human nature. James, with ſuch aſſiſtance, determined to try how far the church of England would agree in the practical aſſertion of the doctrine of non-reſiſtance. He was ſet upon introducing popery as the eſtabliſhed religion of the country. He laid pretenſions to a power of diſpenſing with the known laws; he inſtituted an illegal eccleſiaſtical court, and openly received and admitted into his privy council the pope's emiſſaries, and gave them more reſpect than was due to the miniſters of a ſovereign prince. He ſent an embaſſy to Rome, and received, at his court, the pope's nuncio, and, to crown all, his encroachments upon the civil and religious liberties of his people were carried beyond all bounds, even to the diſguſt of Roman catholics themſelves; and the pope was too good a politician not to know that the courſe taken by James muſt eventually ruin the cauſe which he profeſſed to advocate. The church of England took the alarm, when the king had ordered a declaration to be read, by which every reſtraint on popery was removed. Seven biſhops refuſed to comply with their ſovereign's order, and preſented a petition to excuſe their refuſal. They were cited before the council to anſwer for their conduct, and adhering to their reſolution, were committed to the Tower, proſecuted by the attorney-general for ſedition, tried, and gloriouſly acquitted. The joy of the people, on this occaſion, was inexpreſſible: the city and the country ſeemed at once to catch the ſhouts of exultation. James heard the intelligence with ſullen ſilence, and evident indignation, while he was at dinner in his camp. From the church he turned to his army, who proved equally hoſtile to his views. Oppoſition, however, ſerved only to increaſe his zeal, till at length ſome of the principal people in the country reſolved to apply for relief to William, prince of Orange, who was at once the nephew and ſon-in-law of James II. William, who was an able politician, and ambitious of wearing the crown of England, readily liſtened to the propoſals made him, embarked in their cauſe, and landed a large army almoſt before his deſigns were ſuſpected by the court of James, who, in a few days deſerted their old maſter, and ſought protection from the new. The old king was now deeply convinced of his errors, and would gladly have retracted his meaſures, but it was too late: he found himſelf abandoned by his army and fleet, and learnt, with apparent conſternation and horror, that the prince of Denmark and his favourite daughter Anne had gone over to the prince of Orange. On this intelligence he is ſaid to have wept bitterly, exclaiming, “God help me, my own children have forſaken me.” He now hung over the precipice of deſtruction, invaded by one ſon-in-law, abandoned by another, hated by his ſubjects, and held in utter deteſtation by the friends and relations of thoſe who had ſuffered by his cruelty. He aſſembled the few noblemen who ſtill adhered to his cauſe, and demanded their advice and aſſiſtance. Addreſſing himſelf to the earl of Bedford, father to lord Ruſſel, who had been beheaded at the inſtigation of James in the preceding reign, “My lord,” ſaid the dejected monarch, “you are an honeſt man, have great credit, and can do me ſignal ſervice.” “Alas! ſir,” replied the earl, “I am old, and very feeble, and can afford you but little ſervice, but *I once had* a ſon that could have aſſiſted you in this extremity, but he is no more.” James was ſo ſtruck with the reply, that he could not ſpeak for many minutes. After this he almoſt inſtantly reſolved to abandon his country, and ſeek for himſelf, his queen, and his ſon, real or pretended, then only ſix months old, an aſylum in France, where he paſſed the remainder of his life among a people who pitied, ridiculed, and deſpiſed him.

From this moment the conſtitution of England, which had fluctuated for ages, was fixed. The nation, repreſented by its parliament, determined the long conteſted limits between the king and the people: they preſcribed to the prince of Orange the terms by which he was to rule, and appointed him king jointly with Mary, who was the next proteſtant heir to the crown. They were ſhortly after crowned by the titles of William III. and Mary, king and queen of England. The prince had his ambition amply gratified, and his wiſdom was repaid with that crown which the folly of his predeceſſor had thrown away.

The power of William was limited on every ſide, and he met with an oppoſition from parliament which he did not expect. His chief object was to humble the power of France, and he fully anticipated the utmoſt efforts of the Engliſh to ſecond his views, but he found them more intent upon guarding their domeſtic liberties than eager againſt continental powers: notwithſtanding this, his reign was ſpent in an almoſt uninterrupted courſe of hoſtilities with France, at an expence ſhe had never known before. The nation had grown cautious through the experience of the two laſt reigns, and he gave his conſent to the “bill of rights,” by which the liberties of the people were confirmed and ſecured, though not in ſo ample a manner as might have been done at a criſis when a crown was beſtowed by the free voice of the people. The laſt two kings had made a very bad uſe of the whole national revenue, of which they had an unlimited uſe, and it was found in their hands quite ſufficient to raiſe and maintain a ſtanding army. The revenue was now divided, part of it was allotted for the national ſervice of the year, and was to be accounted for to parliament; and part, which has ever ſince been denominated the civil liſt money, was given to the king for the ſupport of his houſe and dignity.

William was averſe from perſecution, and began his reign by attempting a repeal of thoſe laws that enjoined uniformity of worſhip, and though he could not do all he wiſhed, yet he obtained practical toleration for the diſſenters; and the laws againſt the papiſts were rarely executed. He was, however, a ſtickler for what he regarded as the privileges of the crown, and often controverted, and remonſtrated againſt the views of his parliament, and was, not unfrequently, arbitrary in his councils. He oppoſed with the utmoſt vehemence the bill for triennial parliaments, and, when it had actually paſſed the two houſes, he refuſed to give it his royal aſſent. The houſe of commons, who are or ought to be the repreſentatives of every individual in the country, took fire at this abuſe of the royal prerogative, and voted, with becoming ſpirit, “that whoever adviſed the king to this meaſure was an enemy to his country,” and no king has ſince ventured upon ſo outrageous a proceeding. The bill, thus rejected, lay dormant till the next ſeſſions, when William found himſelf obliged to comply. The ſame oppoſition and the ſame ſucceſs attended a bill for regulating trials in caſes of high treaſon, by which the accuſed was allowed a copy of his indictment, and a liſt of the names of his jury, two days before his trial, together with counſel to plead in his defence, and that no perſon ſhould be indicted but upon the oaths of two witneſſes. It was by inceſſant ſtruggles againſt the crown that the invaluable rights of the people have been tranſmitted to their poſterity; and a juſt regard to theſe rights, civil and religious, was what led them to agree to the revolution. In other reſpects they had no reaſon to deſire a change, nor can it with juſtice be imputed to the Engliſh that they affect important national revolutions. When James was diſmiſſed, the wealth and proſperity of the nation were at their higheſt pitch, the tonnage of their ſhipping, both for merchandize and war, had been nearly doubled in the laſt 25 years: the increaſe of the cuſtoms, the ſureſt teſt of increaſing commerce, and the annual rental were nearly in the ſame proportion. Hence a ſtrong party was formed againſt the king's ambitious and warlike purſuits, which were not always ſucceſsful, and which drained the country of much wealth. The Iriſh were ſtill deſirous of a Stuart king, as were many of the Engliſh, though they ſpurned the idea of having even James forced upon them by the right of conqueſt. Parliament enabled the king to reduce Ireland, and to gain the famous battle of Boyne, (ſee BOYNE,) which cruſhed all the hopes of the exile king, and in 1692 the marine of France, which had hitherto vied with that of England, received an irrecoverable blow in the defeat at La Hogue.

Invaſions were threatened, and conſpiracies diſcovered every day againſt the government, and the ſupplies required to carry on a continental war obliged the parliament to open new reſources for money. A land-tax was impoſed, and every one's lands were taxed according to their valuations given in by the ſeveral counties. To this reign alſo we are indebted for the moſt important operation in finances that ever took place, which was the carrying on the war by borrowing money upon parliamentary ſecurities, and which form what are called the public funds. The projector of this ſcheme, which has been acted upon, beyond the limits of human imagination, (ſee DEBT, *National*,) was Mr. Charles Montague, afterwards lord Halifax. The argument on which he depended to carry his plan into effect, was that it would oblige the moneyed part of the nation to become the zealous and ſteady friends of the revolution, becauſe, after having lent their money to the nation, they could have no hopes of repayment or even of intereſt for it, but by ſupporting the exiſting government.

Notwithſtanding the advantages which the nation derived from the adminiſtration of William, he was ſubject to ſo many mortifications from his parliament, that he ſeriouſly reſolved to abdicate his throne, a reſolution which he with difficulty abandoned, and certainly with the hope of being ſupported more effectually in the war with France, but he was in a great meaſure diſappointed, and obliged to conclude the peace of Ryſwick in the year 1697; and in the general pacification, the only equivalent obtained by the nation for an immenſe waſte of blood and treaſure, was the king of France's acknowledgment of king William's title to the crown.

One of the laſt and moſt important acts of this reign was the paſſing of a bill for ſettling the ſucceſſion to the crown in the houſe of Hanover, which received the royal aſſent in June 1701. Shortly after this the king felt his conſtitution giving way, which he endeavoured to counteract by the exerciſe of riding, and in one of his excurſions to Hampton court, his horſe fell under him, and he himſelf was thrown off with ſuch violence that his collar-bone was ſeverely fractured, an accident which, in a few days, put an end to his life, in the 52d year of his age, and the eleventh of his reign. The character of this prince will be more particularly given under his own name. It may, however, be obſerved in this place, that he was ill formed for acquiring popularity: his manners were cold and forbidding, and he ſometimes ſeemed almoſt loſt to thoſe principles of liberty, for the ſupport of which he had been raiſed to the throne. Nevertheleſs, the reſcue and preſervation of religion, and public liberty, were the chief glory of William's reign, for under his auſpices England ſuffered grievouſly in her actions both by ſea and land, and the public debt at the time of his death amounted to the ſum of fourteen millions ſterling.

The ſucceſſor to William was Anne, the ſecond daughter of king James by his firſt wife. She aſcended the throne in the thirty-eighth year of her age, having ſuffered many ſevere mortifications during the reign of the late king, but upon her acceſſion ſhe followed his ſteps, and ſhortly after declared war againſt France, appointing the earl, afterwards the duke of Marlborough, to the command of her armies. Under this general many important victories were achieved. Thoſe of Blenheim and Ramillies gave the firſt effectual checks to the French power. By the former, in 1704, the emperor of Germany was ſaved from impending deſtruction, and 20,000 of the enemy were ſaid to have been killed, wounded, or drowned in the Danube. About the ſame time ſir George Rooke reduced the famous fortreſs of Gibraltar, which ſtill remains in our poſſeſſion a monument of the bravery and talents of the Engliſh admiral. The battle of Ramillies, fought in 1706, was of the utmoſt importance to the cauſe for which the war was undertaken; *viz.* to place Charles duke of Auſtria on the throne of Spain, for immediately after that victory, the ſtates of Flanders aſſembled at Ghent, and recognized Charles for their ſovereign. In Spain itſelf the Engliſh were unſucceſsful; the burdens of the war falling chiefly on this country, the people, who are ever delighted at victory, began to murmur at the taxes impoſed on them. Other circumſtances led to diſputes reſpecting the prerogative, the ſucceſſion, and religion, which created great ferments in the nation and parliament. Negociations for peace were carried on ſome time, but without ſucceſs. At this period the leading parties in the nation were whigs and tories, at the head of the former was the duke of Marlborough, who ſupported by the queen was for a continuance of the war, in which her majeſty concurred, till means were found to convince her, that it would finally prove ruinous to her and the people, and that the whigs were inimical to the national religion. The cry of "the church is in danger," at length diſplaced the whigs, and even drove the duke of Marlborough from the command of the army, an act which excited the aſtoniſhment of all Europe, for ſo numerous had been the victories acquired by his valour, and ſo high was his reputation, that his name was equivalent to an army. There is little doubt that whatever the faults of the whigs might have been, the honour and intereſts of the nation were ſacrificed to court intrigues and private cabals. In the midſt of all the diſputes the whigs accompliſhed the union between the two kingdoms of England and Scotland, which has proved of great benefit to both, but which at the time excited the moſt violent clamours againſt the projectors. The Engliſh expected nothing from the union of ſo poor a nation, but a participation of their neceſſities: they contended it were unjuſt that while Scotland was granted an eighth part of the legiſlature, it yet ſhould be taxed only a fortieth part of the ſupplies. The Scots, on the other hand, conceived that their independency would be wholly deſtroyed, and the dignity of the crown betrayed; they dreaded an increaſe of taxes, and were not very anxious for an increaſe of trade. After ſome ineffectual ſtruggles the Union was effected: Scotland was no longer to have a parliament, but to ſend ſixteen peers, choſen by their nobility, and forty-five commoners, to the Engliſh parliament, and from that period the two kingdoms were called by the common name of Great Britain, and all the ſubjects of both were to enjoy a communication of privileges and advantages.

In 1712 conferences for negociation between England and France were opened, which led to peace. This was condemned by the whigs as injurious to the honour and intereſt of the nation. The majority of the houſe of lords inclined to that party, but that of the other houſe was tories. The queen, dreading that the lords might reject the terms of peace, by an unprecedented exerciſe of her authority, created twelve peers at one time, which ſecured the approbation of the parliament for the peace. The remainder of this reign was a ſcene of contention between the two parties. Each reviled the other in turn, and theſe commotions ſerved ſtill more to impair the queen's health, till at length ſhe felt herſelf unequal to the duties of her ſtation. She ſunk into a ſtate of inſenſibility, and found a refuge from her anxiety and cares in lethargic ſlumber. Every precaution was taken to ſecure the ſucceſſion in the houſe of Hanover, and orders were ſent to the heralds at arms to be in readineſs to proclaim the elector of Brunſwick king of Great Britain. The day before the queen died ſhe ſeemed to revive, roſe from her bed, and walked about, when, caſting her eyes on the clock that ſtood in her chamber, ſhe continued to gaze for ſome time, and being aſked what ſhe ſaw more than uſual, ſhe replied only with an expreſſive but dying look, and about ſeven o'clock the next morning, Aug. 1, 1714, ſhe expired in the thirteenth year of her reign. The national debt had, during this reign, encreaſed from fourteen to fifty millions. See ANNE, CHURCHILL, &c.

With this princeſs terminated the line of Stuarts, which, from the acceſſion of James I. 1603, had ſwayed the ſceptre of England one hundred and eleven years, and that of Scotland 343 years. On the death of queen Anne, there was ſtill left the ſon or ſuppoſed ſon of James II. who had been acknowledged king by the court of France on the deceaſe of his father in 1701. In behalf of this prince, rebellions were excited in England in 1715 and 1745. He reſided at Rome, and kept up an appearance of a court till his death in 1765, leaving two ſons, who are ſince dead and without iſſue.

By the act of ſucceſſion George I. ſon of Erneſt Auguſtus, firſt elector of Brunſwick, and Sophia grand-daughter of James I. aſcended the Britiſh throne; his mother, who would have been next in ſucceſſion, having died a ſhort time before. He arrived in England with ſtrong prepoſſeſſions againſt the tory miniſtry, moſt of whom he diſplaced, without producing much effect in England, but in Scotland a rebellion was excited by ſome of the leading men of that country, who paid for their temerity the forfeit of their lives. Commotions and riots were raiſed in London, Oxford, and other parts, but theſe were happily ſuppreſſed, and the ringleaders in various inſtances were made examples of juſtice. The earl of Oxford, who had negociated the peace of Utrecht, was charged with high treaſon on that account, but the proſecution was abandoned. The ſituation of affairs would not permit the miniſtry to venture upon a new parliament, and the members of that which now exiſted voted a continuance of their duration from three to ſeven years, one of the greateſt and moſt indefenſible ſtretches of parliamentary power ever known. Several other meaſures, hoſtile to liberty and the principles of the exiſting conſtitution, took place at the ſame time. Mr. Shippen, a member of parliament, was committed to the Tower for aſſerting in his place, that the king's ſpeech was better calculated for the meridian of Hanover than of London; and a young man, a printer, was actually hanged for a pamphlet, ſaid to have been ſcarcely deſerving of animadverſion. George I. however ſagacious, and in many reſpects moderate, was too much attached to his German dominions, and rendered England in a great meaſure ſubſervient to them. He quarrelled with the czar of Muſcovy about their German concerns, and had nearly involved this country in a war with Charles XII. of Sweden, for having as elector of Hanover purchaſed Bremen and Verden of the Danes. In 1718, he quarrelled with Spain on account of the quadruple alliance that had been formed between Great Britain, France, Germany, and the States General, and admiral ſir George Byng, by his orders, deſtroyed the Spaniſh fleet. The war was quickly terminated by the Spaniards delivering up Sardinia and Sicily, the former to the duke of Savoy, and the latter to the emperor, and by the king of Spain conſenting to ſign the quadruple alliance, in which England was very little if at all intereſted. See ALLIANCE.

The next thing of importance was the ſecuring the dependency of the Iriſh parliament upon that of Great Britain. The houſe of peers in England had reverſed a decree made by the Iriſh houſe, which excited long, animated, and even bitter diſcuſſions, till at length a bill was brought into the Engliſh parliament, by which the Iriſh houſe of lords was deprived of all right of final juriſdiction, which, notwithſtanding the moſt violent oppoſition from ſeveral leading members of both houſes, was carried by a great majority. The ferment occaſioned by theſe diſcuſſions was followed by the South Sea ſcheme, which promiſed immenſe wealth to thoſe who engaged in it, but which left a large part of the nation in diſtreſs and ruin. (See BUBBLE.) Juſtice was demanded, by petitions from all parts, upon the contrivers of the ſcheme, and the nation ſeemed, as to a man, highly exaſperated. During theſe tranſactions, the king, with ſerenity and wiſdom, preſided at the helm, influenced his parliament to purſue equitable meaſures, and, by his councils, endeavoured to reſtore the credit of the nation. The diſcontented availed themſelves of public calamities, and made another attempt againſt the reigning ſovereign. Their deſigns were ſoon detected, and Chriſtopher Layer, a young gentleman of the Middle Temple, was convicted of treaſonable acts, and ſuffered death on the account. Several noblemen and other perſons of diſtinction were ſuſpected of being in the plot, but of theſe the biſhop of Rocheſter was the only victim who was baniſhed the kingdom for life. After the ferment which this plot occaſioned was over, the tranſactions of the reign were few and leſs important in their conſequences. The miniſtry, who were all in the intereſt of Hanover, ventured upon ſeveral bold meaſures, in ſome of which the national intereſt, if not honour, was evidently ſacrificed to that of the electorate. The crown of Great Britain was engaged in every continental diſpute, however remote it was from her own intereſt. Treaties lately concluded with Spain were again broken, and admiral Hoſier was ſent to intercept the Spaniſh galleons from America, an expedition which proved as fatal as it was inglorious. The admiral and moſt of his men periſhed by epidemical diſeaſes, and the hulks of his ſhips rotted ſo as to render them utterly unfit for ſervice. To retaliate, the Spaniards undertook the ſiege of Gibraltar, and with ſimilar ſucceſs. New treaties were ſet on foot, France offered its mediation, and a reconciliation was effected. The king died, as he was travelling to his Hanoverian dominions, at Oſnaburgh, on the 11th June 1727, in the thirteenth year of his reign. During his reign the ſinking fund for diminiſhing the national debt was inſtituted. See DEBT *National*, FUNDS, &c.

Upon the death of George I. his ſon George II. aſcended the throne, with a predilection for his Hanoverian dominions ſimilar to that of the late king. He choſe for his firſt miniſter ſir Robert Walpole, who had filled the ſame high office under his father. This able miniſter was a decided enemy to war, which, in ſome inſtances, led him into difficulties both at home and abroad. His adminiſtration will be more properly conſidered under the article attached to his name, (ſee WALPOLE,) but juſtice requires of us to obſerve, that notwithſtanding ſome of his meaſures, as an attempt at the introduction of the exciſe laws, were liable to great cenſure, yet he was friendly to the exiſting laws: he filled the courts with able and upright judges, and he has not been charged with any attempt at the violation of the known law of the kingdom, and under his adminiſtration the preſs was under little or no reſtraint. His pacific ſyſtem more than repaid to the nation all that was required to ſupport it, by the increaſe of her trade and the improvement of her manufactures. The great objects of controverſy during the early part of this reign were the national debt, and a ſtanding army. Demands for new ſupplies were made every ſeſſion of parliament, either for the purpoſe of ſecuring friends on the continent, or of guarding the internal polity, or for enabling the miniſtry to act vigorouſly in conjunction with their allies abroad. Theſe were as regularly oppoſed as they were made: the ſpeakers of the country party ever inſiſted, that the Engliſh had no buſineſs to embroil themſelves with the affairs of the continent; that expences were incurred without prudence or neceſſity; and that the increaſe of the national debt by multiplying taxes, would in the end become intolerable to the people. A motion was made to revert to the old ſyſtem of triennial parliaments, as they had been ſettled at the revolution. The advocates for this meaſure aſſerted that the ſeptennial act was an encroachment on the rights of the people; that it was introductory to the monſtrous corruptions of government: that during the continuance of that parliament which prolonged its exiſtence from three to ſeven years ſeveral ſevere laws had been enacted; that by one of theſe a man might be removed, and tried at any place where the jury might be found favourable to the crown, and where a priſoner's witneſſes could not and dared not come; that by another, a juſtice of peace was empowered to put the beſt ſubjects to death after reading the riot act. The miniſtry was, however, triumphant, and the oppoſition, who, unqueſtionably, had the weight of argument on their ſides, complained that debate was uſeleſs, and that it was wholly impoſſible that reaſoning could prevail over the corruptions that were ſecretly practiſed by the miniſter. Deſpairing, therefore, of being able to ſtem the torrent of corruption, they retired to their ſeats in the country, and left the miniſtry an undiſputed majority in the houſe.

In November 1737, queen Caroline, conſort to the king died; at this time the king and his ſon Frederick the prince of Wales were at variance. The latter complained that through Walpole's influence he was deprived not only of the power but the proviſion to which his birth was entitled. The king forbade him his preſence, and gave orders that none of his friends ſhould be admitted at court. A motion was made in the houſe of commons for increaſing the prince's ſettlement, which was fifty thouſand pounds; this was oppoſed by ſir Robert Walpole, and rejected by a large majority. The prince now placed himſelf at the head of the oppoſition with ſo much firmneſs, that it was ſeen Walpole's power was drawing to a criſis; but it was not till the year 1742 that he reſigned his employments and was created earl of Orford. The king bore the loſs of his miniſter with the greateſt equanimity, and even conferred titles of honour, and poſts of diſtinction upon the heads of oppoſition. Circumſtances alſo aroſe which induced him to take a leading part in a continental war: in oppoſition to which a rebellion in behalf of the pretender was excited in 1745 in Scotland. Charles, the ſon of the pretender, landed in the Scottiſh iſlands, and ſoon found himſelf at the head of 1500 men. Manifeſtoes were widely diſperſed, inviting the highlanders to join in the cauſe: few, however, ſeemed willing to hazard the dangers of the enterprize. Its boldneſs aſtoniſhed Europe; it awakened the fears of the puſillanimous, the pity of the wiſe, and the loyalty of all. The whole kingdom ſeemed unanimouſly bent upon oppoſing the enterprize which they were ſenſible, as being ſupported only by papiſts, would be inſtrumental in reſtoring popery. The rebels advanced to Perth, where, inſtead of proceeding with increaſed rapidity, they ſtaid to proclaim the prince's father king. The prince was again ſucceſsful at Preſton Pans, and marched to Edinburgh; here he waſted his time in diſſipation and parade, till an opportunity was given to the king to ſend againſt him an effectual force under the duke of Cumberland. The battle of Culloden on the 15th of April 1746, put an end to all hopes of the pretender: the victory on behalf of the king was complete, but the mercileſs fury of the conquerors upon the fallen diſgraced the cauſe, to which every friend of his country wiſhed ſucceſs. The duke ordered nearly forty deſerters to inſtant execution, and the royal army ſpread terror wherever it came, and after a few days the whole country was one ſcene of ſlaughter, deſolation, and plunder; juſtice was forgotten, and every virtue ſeemed to be loſt in the moſt ſavage vengeance. The government on this occaſion was not a little indebted for the ſupport it received to the national debt. The Jacobite party had hoped to ruin public credit, but common danger aboliſhed all diſtinctions, and united them in defence of private property. The merchants agreed to receive bank notes in payment, which prevented the miſchief that was hoped for by a run upon the bank. The defeat of this rebellion in the year 1746 did not reſtore tranquillity to Europe; it was not till after various ſucceſſes in different parts of the globe that the preliminaries of peace were ſigned in April 1748, and in the October following a definitive treaty was concluded at Aix-la-Chapelle. In the proſecution of this war the balance of gain, as far as wealth was concerned, was evidently in favour of Great Britain, and many private perſons made it ſubſervient to the attainment of vaſt fortunes. In the following year, the intereſt of the national debt was reduced from four to three and a half *per* cent. at which rate it was to continue for the next ſeven years, when it was to ſuffer a farther reduction to three *per* cent. This, ſays the hiſtorian, was the boldeſt ſtroke of financing that ever was attempted perhaps in any country, conſiſtently with public faith, for the creditors of government, after a trifling ineffectual oppoſition, continued their money in the funds, and a few who at firſt ſold out were glad, in a ſhort time, to have it placed under the ſame ſecurity.

At this period Mr. Pelham was the miniſter of the country, who turned his attention to the improvement of commerce, manufactures, and fiſheries, the benefits of which deſcended to poſterity. A new treaty of commerce was ſigned at Madrid, between Great Britain and Spain, by which, in conſideration of 100,000*l.* the South Sea Company gave up all their future claims to the Aſſiento contract, by virtue of which that company had ſupplied the Spaniſh Weſt Indies with ſlaves from the coaſt of Africa. (See ASSIENTO.) In March 1750, his royal highneſs Frederic prince of Wales died, to the regret of the nation: and in the following year an act was paſſed for regulating the commencement of the year, by which the old ſtyle was aboliſhed, and the new ſtyle eſtabliſhed, which was done by ſinking eleven days in 1752, and from that time the year was to begin the firſt of January inſtead of March. (See Calendar.) In 1753 the famous act was paſſed for preventing clandeſtine marriages, which at the time excited the moſt violent oppoſition, as replete with the moſt injurious conſequences to the liberties and morality of the people, and as making an impaſſable line between the rich and the poor: and about the ſame time an act equally, or even more unpopular, as attacking the religious prejudices of the people, was paſſed. This was a law for naturalizing the Jews, which, though carried through great oppoſition, was in the next ſeſſion repealed. The game laws were alſo introduced about this period; by theſe none but men poſſeſſed of certain property could have the privilege of carrying a gun, or of otherwiſe deſtroying game, though on grounds which they rented themſelves. This meaſure was ſuppoſed to be a violent encroachment on the liberty of the ſubject; that it would neceſſarily damp the martial ſpirit of the lower orders of ſociety, by preventing them from handling thoſe arms which might one day be neceſſary to defend their country; and at the ſame time, that it gave the rich the ſole enjoyment of a pleaſure, which before had been conſidered as the common privilege of humanity. "Such," ſays a contemporary writer, "were the laws paſſed at this period, through all which a ſpirit of ariſtocracy was diſcerned by ſome. The body of the rich, no longer fearing oppreſſion from the throne, or an infringement of their own liberties, now began to lean heavy on the poor, and to conſider the intereſts of that uſeful part of the ſociety as entirely diſtinct from their own. They never omitted, however, their uſual addreſſes to the throne; and this ſeſſion (1756) was remarkable for an addreſs of thanks to his majeſty, for maintaining, and rendering permanent, the general tranquillity of Europe, at a time when war was kindling in almoſt every quarter of the world."

To the conduct of this war Mr. Pitt was called, as ſecretary of ſtate, and head of the adminiſtration. He had long ſignalized himſelf as a bold, eloquent, and energetic ſpeaker, and he ſoon proved himſelf a moſt able and ſpirited miniſter. In this war the Engliſh in Europe, in Aſia, and America, achieved wonders: they were every where victorious: almoſt all the poſſeſſions of the French in North America and in India fell into our hands; and at the battle of Minden, in Germany, ſeven thouſand of our countrymen defeated an army more than ten times as large. The Engliſh for ſome time bore the increaſing burdens of warfare with cheerfulneſs; and rendered, by every means in their power, the juſt tribute of praiſe to the talents and activity of the miniſter. But at length, glutted almoſt with victory ſucceeding upon victory, they began to reflect upon the proble advantages that might reſult from a continuance in war, when it was evident that the conqueſts made in Germany muſt ever be foreign to the real intereſts of Great Britain; that they were waging an unequal war, and adding new loads of taxes to thoſe already difficult to be borne, for conqueſts which they could neither preſerve nor enjoy. Such were the growing diſcontents of the people, when the French ſhewing ſome diſpoſition to treat for peace, and the charges of the war beginning to amount to eighteen millions a-year, inclined the Britiſh miniſtry to liſten to the propoſals offered them. A negociation was accordingly entered upon, but without ſucceſs. This was in the autumn of the year 1760, and on the 25th day of October, 1760, George II., without any apparent ſymptoms of diſorder, was found expiring in his chamber. He had ariſen at his uſual hour, intending to walk out, but being left alone, he was heard to fall down upon the floor; the noiſe of the fall brought his attendants into the room; he deſired, in a faint and faultering voice, that the princeſs Amelia might be ſent for, but before her arrival he expired, in the 77th year of his age, and the 33d of his reign, in the midſt of victory, and at that very period, when the univerſal enthuſiaſm of conqueſt began to ſubſide into more ſober reflections. The character of this prince will be given under his own name. He was ſucceeded by his grandſon George III., the preſent ſovereign, who aſcended the throne with great advantages. He took the opportunity which his firſt ſpeech to parliament gave him, of appealing to the prejudices and affections of his people. "Born and educated in this country," ſaid he, "I glory in the name of Briton, and the peculiar happineſs of my life will ever conſiſt in promoting the happineſs of a people whoſe loyalty and warm affection to me I conſider as the greateſt, and moſt permanent ſecurity of my throne. The civil and religious rights of my loving ſubjects are equally dear to me with the moſt valuable prerogatives of my crown." The firſt acts of this reign were calculated to convince the people that the war in which they were engaged ſhould be carried on with energy; very brilliant ſucceſſes, and important conqueſts, were the reſult of the plans adopted by Mr. Pitt, who felt himelf reſponſible for almoſt all public meaſures. When, however, he found his influence in the cabinet declining, through the ſuppoſed intrigues of the earl of Bute, he reſigned his high ſituation, declaring he would no longer lie under the reſponſibility of meaſures which he was not allowed to guide. Mr. Pitt retired in October 1761, upon a penſion of 3000*l.* *per ann.* and, at the ſame time, a peerage was conferred upon his lady. Theſe grants were, by his enemies, held out as proper ſubjects to excite the popular clamours againſt the patriotic miniſter. At firſt they ſucceeded, but in a ſhort time an almoſt general diſcontent prevailed in the nation, on account of his removal from office, in the midſt of a war, which he had conducted with ſo much honour to himſelf and to his country, and in a manner that had excited the aſtoniſhment of Europe. The war was ſtill purſued with vigour, and the plans of Mr. Pitt, of which the new miniſter availed himſelf, led to important victories both by ſea and land.

Early in the year 1763, peace was agreed upon, and of ſo little importance had the war been to the intereſts of the Engliſh, who had been almoſt uniformly victorious, and who had acquired by their valour many foreign poſſeſſions, that it was agreed a mutual reſtitution and oblivion ſhould take place, and each party ſit down at the end of the war in the ſame ſituation in which they began it. The peace excited much oppoſition, becauſe the terms were thought extremely inadequate to what might have been expected from the numerous and brilliant victories and advantages obtained in the courſe of a long war. From this period various cauſes contributed to occaſion a ſpirit of diſcontent in the nation. On the 30th of April, 1763, three of the king's meſſengers entered the houſe of Mr. Wilkes, member of parliament for Ayleſbury, and ſeized his perſon by virtue of a warrant from the ſecretary of ſtate, which directed them to ſeize the authors, printers, and publiſhers, of a ſeditious and treaſonable paper, entitled the North Britain, N° 45. This work contained ſtrictures on his majeſty's ſpeech, and Mr. Wilkes was ſuſpected to be the author. He was accordingly arreſted, examined, and cloſely impriſoned, which gave riſe to diſcuſſions on the legality of general warrants, which were in the end declared illegal, and a groſs violation of the liberty of the ſubject. (See Warrants, *General.*) Mr. Wilkes was for this and other publications expelled the houſe, and in 1764 a ſentence of outlawry was iſſued gainſt him.

In 1765, under the adminiſtration of Mr. George Grenville, an act was paſſed for laying a ſtamp-duty on the Britiſh colonies of North America. This kindled a flame in that quarter of the globe, which finally led to a ſeparation of the colonies from the mother country, and eſtabliſhed the independence of America. (See AMERICA and UNITED STATES.) In the year 1768 Mr. Wilkes returned to England, was proſecuted, convicted, and fined in the ſum of 1000*l*. He carried with him the voice of the people, whoſe cauſe he was ſuppoſed to vindicate, and was again elected member for Middleſex; and was again expelled. After the expiration of the term of his impriſonment, in the year 1771, he was elected ſheriff of London, and afterwards choſen member for the county of Middleſex, when he was permitted quietly to take his ſeat; and in the year 1775 he was elected lord mayor of London, an office which he executed to the ſatisfaction of his fellow-citizens. In 1783 all the declarations, orders, and reſolutions of the houſe of commons, reſpecting his election for the county of Middleſex, were ordered to be expunged from the journals of that houſe.

In the year 1772 the clergy petitioned the parliament for relief in matters of ſubſcription to the 39 articles, praying to be reſtored to their undoubted right of interpreting ſcripture for themſelves, without being bound by any human explanation of it, or being required to acknowledge by ſubſcription or declaration, the truth of any formulary of religious faith and doctrine whatever, excepting the Holy Scripture itſelf. The petition was preſented by ſir William Meredith, who, with other members favourable to the principle, enforced it by many arguments drawn from the principles of toleration. It was, however, rejected by a large majority. A bill was ſhortly after brought into the houſe to prevent the deſcendants of his late majeſty from marrying without the conſent of his majeſty, his heirs, and ſucceſſors, which was carried very rapidly through both houſes, and paſſed into a law. A petition was now preſented by the diſſenters, praying to be relieved from the hardſhip of ſubſcribing to the articles of a church to which they did not belong. This petition was received, and a bill brought into the houſe founded upon it, which was carried by a large majority in the commons, but which was rejected in the houſe of lords. From this period the whole intereſt of the country was turned to the conteſts with America, to which we have already referred. The enormous expences occaſioned by this war excited much and almoſt general diſcontent among the people, who began to call aloud for an economical reform in the various departments of the ſtate. Meetings were held in various counties of the kingdom, at which great numbers of freeholders were preſent, who agreed to petition the houſe of commons, "that before any new burdens were laid upon the country, effectual meaſures might be taken by that houſe to inquire into, and correct the abuſes in the expenditure of the public money; to reduce all exorbitant emoluments; to reſcind and aboliſh all ſinecure places, and unmerited penſions; and to appropriate the produce to the neceſſities of the ſtate." In the beginning of the year 1780 theſe petitions were taken into conſideration, and ſome trifling reforms took place. In ſome inſtances, the miniſter, lord North, was left in a minority, and in many others he was obliged to uſe every exertion to carry his meaſures. In a very full houſe, and by a ſmall majority, certain officers under the crown were excluded from having ſeats in the houſe of commons: this they hoped to follow by other arrangements favourable to the rights of the people; but, in a ſhort interval, the miniſter was enabled to apply arguments not generally underſtood, but ſtrongly ſuſpected, which gave him a preponderance in the houſe, and which enabled him to ſtop the progreſs of reform. The people were diſſatisfied, and a ſpirit of diſcontent prevailed in almoſt every part of the kingdom. About this period, the hardſhips which individuals, profeſſing the Roman Catholic religion, had laboured under, awakened the conſideration of the liberal part of the people: and ſome perſons of high conſideration in the ſtate undertook their cauſe, and fully expected they ſhould obtain for them that relief which the nature of their caſe required. The Catholics preſented a dutiful and loyal addreſs to the king, containing the ſtrongeſt aſſurances of affection and fidelity to his perſon and the civil government of the country. This addreſs, which was drawn up with great care, and which contained ſentiments of the moſt unexceptionable nature, was ſigned by ſeveral Roman Catholic peers, and 63 commoners of rank, fortune, and influence in the country. The advocates of the cauſe were aware that the prejudices of the lower claſſes were hoſtile to an extenſion of the privileges of the Catholics, whom they had been accuſtomed to regard as perſecutors from principle, and as deſirous of ſubverting the Proteſtant faith. But ſir George Saville made a motion for the repeal of certain penalties which were attached to the profeſſion of the Catholic religion. He was ſeconded in his exertions by Mr. Dunning, who laid before the houſe an account of the ſtatutes ſtill exiſting againſt the Catholics, by which, among other grievances, it was made high treaſon in any native of theſe realms to teach the doctrines or perform divine ſervice according to the rites of that church; the eſtates of perſons educated abroad in that perſuaſion were forfeited to the next proteſtant heir; a ſon, or any other, the neareſt relation being a Proteſtant, was empowered to take poſſeſſion of his own father's or neareſt of kin's eſtate, during their lives; a Roman Catholic was diſabled from acquiring any legal property by purchaſe. In conſequence of theſe and ſuch like repreſentations, the motion made in favour of the Roman Catholics was received without a diſſenting voice, and a bill in purſuance of its intent was brought in and paſſed both houſes. This act ſeemed to give little offence to perſons of any claſs in England, but in Scotland it excited much indignation, riots enſued, and ſome houſes and chapels were deſtroyed. The contagion at length reached England: a number of perſons aſſembled themſelves together with a view of promoting a petition to parliament for a repeal of the late act in favour of the Papiſts, and they aſſumed the title of "The Proteſtant Aſſociation." Of this aſſociation lord George Gordon was the preſident: who, at the head of 50,000 men, preſented a petition to the houſe of commons on the 2d day of June 1780 At firſt the petitioners behaved with order and decency, but they ſoon became violent againſt the members of the two houſes, who had been friendly to the cauſe of toleration, ſome of whom narrowly eſcaped with their lives. From this time till the 7th of June, London was the ſcene of the moſt atrocious crimes: houſes, chapels, and priſons, were broken open, plundered, and burnt. In one night, and at the ſame hour, it is ſaid, there were 36 buildings on fire. Attempts were made on the bank, but ſuch precautions had been taken as to render that place invulnerable. At length by the exertions of the military, who killed and wounded great numbers of the rioters, the tumult was ſuppreſſed, and the metropolis reſtored to order and tranquillity. Numbers were afterwards tried for aiding and abetting in theſe ſcenes; ſome were convicted and executed, and others acquitted; and the preſident lord George

Gordon was committed to the Tower on a charge of high treaſon, for which he was afterwards tried and found "Not Guilty."

War continued to rage, and from America it had ſpread to almoſt every part of the world, and the Engliſh found themſelves engaged in a conteſt with France, Spain, and Holland: but in the beginning of the year 1782 the oppoſition ſucceeded in forcing miniſters to a pacification. Peace was accordingly concluded, but not ſuch a peace as met the general wiſhes of the people, and thoſe who had made it were obliged to reſign their places to the famous coalition miniſtry under lord North and Mr. Fox. By the latter a bill was brought into parliament, for newly regulating the government of the Eaſt India Company, which occaſioned a great ferment in the country, and which finally drove the author of it, and his party from the helm, who were ſucceeded by the late Mr. Pitt and his friends. One of the firſt acts of this miniſter was a new Eaſt India bill, which was paſſed by a great majority: and ſhortly after, he became the advocate of parliamentary reform, a cauſe which he had eſpouſed before he came into place, and which he pledged himſelf to uſe his utmoſt endeavours to carry into effect. His plan was rejected, and from that time he never ſeriouſly attempted to realize the expectations which he had excited among the friends of liberty. The next important meaſure which he introduced to the notice of parliament was the propoſal of a ſinking fund to be applied towards diſcharging the national debt. (See Debt, *national.* *Sinking* Fund, &c.) We ſhall alſo refer our readers to the life of that miniſter for a more comprehenſive view of his public adminiſtration: to the article Revolution, *French*, for the various occurrences that took place in this country from the year 1788; to the article Slave *Trade* for an account of the proceedings on that ſubject to its final abolition: to the article Test *act* for the attempts made in this reign to obtain a repeal of thoſe obnoxious laws, &c. &c. Henry's Hiſt. Rapin. Act. Regia. Hume. Belſham. Biog. Brit. &c.

England, *Little, beyond Wales*, in *Geography*, is a portion of country lying along the ſouth-weſtern coaſt of South Wales, inhabited by the deſcendants of a colony of Flemings; who came over from Flanders, and ſettled here in the reign of king Henry I. Camden ſays, the occaſion of their emigration was an inundation of the ſea, by which a great part of the Low Countries was overflowed. But it has been ſtated, with more probability, that it was the policy of that wiſe monarch to place a people oppoſite in their language, manners, and opinions to the Welſh, to aſſiſt in his favourite project—the ſubjugation of the country. Another colony from the ſame country was incorporated with the firſt, in the time of Henry II., to which occaſionally were added numerous Anglo-Normans, and others from the Engliſh army. At firſt theſe people were confined to the commot of Rhos, which diſtrict ſtill more *particularly* retains the name of Little England beyond Wales. But their numbers increaſing in the courſe of time, they ſoon ſpread along the whole coaſt, from the lordſhip of Comes to the mouth of the river Tave. And this part of the principality is ſtill divided into two diſtricts, denominated Engliſhery, and Welſhery. The latter, occupied by the original inhabitants, contains the cantreves of Comes, Cilgerran, part of Arberth, and Dewiſland. The former compriſes the remainder of Arberth, and the cantreves of Rhos, Caſtel-Martins, and Dougleddy; and is inhabited by the deſcendants of the Flemings. Like their anceſtors, they are a hardy, induſtrious, and adventurous race. The diſpoſitions of the two people are equally ſtriking and adverſe. While the Welſh are hot, eaſily irritated, and obſtinately tenacious; theſe are not eaſily provoked, are averſe to contention, and avoid litigation. Both are diſtinguiſhable by their mode of dreſs, manner of living, the ſtyle of their buildings, particularly in their churches; and the names they reſpectively give to places. All theſe ſtrongly point out the line of demarcation between them. In the Welſhery, not a word of Engliſh is heard ſpoken, while in the next village within the Engliſhery, not a word of Welſh. The language of the latter diſtrict is not much different from the common dialect of England, except in ſome parts of Rhos and Caſtle-Martin. The two people avoid all commerce as much as poſſible, mutually conſidering each other in a degrading light; and even a pathway will divide them in the ſame pariſh. To ſuch an extent is this perſonal deteſtation carried among the lower claſſes, that a matrimonial connection between the oppoſite parties is conſidered by both an unfortunate event. The Flemings, however, eventually proved a bleſſing to Wales, as well as England; by their introduction of the woollen manufactures. And a work, which proves their induſtry and improving ſpirit, is yet viſible. It is a road of great extent made by them, and ſtill called Fleming's way. Evans's Tour in South Wales.

England, *New*, comprehending the *Northern* or *Eaſtern States* of North America, lies around the great bay which ſets up N.W. between cape Cod and cape Sable, between 41° and 48° N. lat., and between 1° 30′ and 10° 15′ E. long. from Philadelphia, and is bounded N. by Lower Canada; E. by the province of New Brunſwick and the Atlantic ocean; S. by the ſame ocean and Long-iſland Sound; and W. by the ſtate of New York. It lies in the form of a quarter of a circle; its W. line beginning at the mouth of Byram river, which diſcharges itſelf into Long-iſland Sound at the S.W. corner of Connecticut, lat. 41°, runs a little E. of N. until it ſtrikes the 45th degree of latitude, and then curves to the eaſtward, almoſt to the gulf of St. Lawrence. Its extreme length is about 626 miles; its breadth is very unequal, from 100 to 200 miles; containing about 72,000 ſquare miles. This grand diviſion of the United States comprehends the ſtates of Vermont, New Hampſhire, Maſſachuſetts (including the diſtrict of Maine), Rhode Iſland, and Providence Plantations, and Connecticut; which ſee reſpectively. The climate of New England is ſalubrious, as we may infer from the longevity of its inhabitants; one in ſeven living to the age of 70 years, and about one in thirteen or fourteen to 80 years and upwards. The moſt prevalent winds are the N.W., W., and S.W.; but the E. and N.E winds, which are inſalubrious, occur frequently at certain ſeaſons of the year, particularly in April and May, on the ſea-coaſts. The weather is leſs variable than in the middle, and eſpecially the ſouthern ſtates, and more ſo than in Canada. The extremes of heat and cold are, according to Fahrenheit's thermometer, from 20° below to 100° above 0; the medium being from 48° to 50°. The quantity of water which annually falls in New England is from 42 to 48, and yet they ſuffer here more from drought than in England, where the annual quantity of water is eſtimated at about 24 inches. Hence it is inferred that the atmoſphere is remarkably dry, and thus ſome have accounted for its ſingular ſalubrity. Winter commonly commences, in its ſeverity, about the middle of December; ſometimes earlier, and ſometimes not till Chriſtmas. The diſeaſes moſt prevalent in New England are alvine fluxes, St. Anthony's fire, aſthma, atrophy, catarrh, colic, inflammatory, ſlow, nervous, and mixed fevers, pulmonary conſumption, quinſy, and rheumatiſm. The general condition of the New Englanders, which precludes the luxury of the rich and the extreme diſtreſs of the poor, affords them an exemption from a variety of diſeaſes, to which a greater degree of inequality might expoſe them. This country preſents to the traveller a great variety of ſurface, conſiſting of extenſive plains, intermixed with vallies of different breadths from 2 to 20 miles, and with mountains of different elevations. Although it may be deemed, upon the whole, to be high and hilly, its mountains are comparatively ſmall, and run nearly N. and S., in ridges parallel to one another. The weſternmoſt range begins in the county of Fairfield, and, paſſing through the counties of Litchfield and Berkſhire, unites with the Green mountains at Williamſtown, in the N.W. corner of the Maſſachuſetts, being ſeparated only by the narrow valley of Hooſack river. The higheſt part of this range is Toghkonnuck mountain in Egremont, the ſouth-weſtern corner of the ſame ſtate. Over this mountain, elevated probably more than 3000 feet above the ocean, runs the boundary between Maſſachuſetts, Connecticut, and New York. The ſecond range is that of the GREEN *mountains;* which ſee. The third range has the ſame commencement with the ſecond at New Haven, in a delightful eminence called the Eaſt rock, and paſſing through the counties of New Haven, Hartford, and Hampſhire, extends into Canada. The Blue hills in Southington, mount Tom, which is the principal eminence, mount Holyoke, and mount Toby in Sunderland, are the principal ſummits of this range S. of New Hampſhire. This range, which is precipitous and romantic, croſſes Connecticut river juſt below Northampton and Hadley in Maſſachuſetts. The ſouth or eaſtern range begins at Lyme in Connecticut, and forms the eaſtern boundary of the Connecticut valley, until it unites with the laſt-mentioned range in the county of Hampſhire; but is leſs diſtinctly marked by eminences than the others. The chief ſingle mountains are Saddle-mountain in Maſſachuſetts, computed to be about 4000 feet above the ſea, Watchuſett in the county of Worceſter, Aſchutney in the ſtate of Vermont, Monadnock in New Hampſhire, and the White mountains in the ſame ſtate, of which the higheſt ſummit is Mount Waſhington, probably between 10,000 and 11,000 feet above the ocean, and the higheſt land in the United States. This mountain is covered during a great part of the year with ſnow, and is ſeen in fair weather at the diſtance of 90 miles from the ſea, and 160 from its baſe. New England abounds in cataracts and caſcades; thoſe of the White mountains being ſingularly romantic and beautiful. The principal rivers of New England are the Schodack, Penobſcot, Kennebeck, Amariſcoggin, Saco, Piſcataqua, Merrimack, Parkers, Charles, Taunton, Providence, Thames, Connecticut, Hooeſtonnuck or Stratford, Onion, La Moille, and Miſſiſconi. The largeſt of theſe are Penobſcot, Kennebeck, Merrimack, and Connecticut. The chief lakes are Champlain and Memphremagog, lying partly in Vermont and partly in New York; Winnipiſiogee and Umbagog in New Hampſhire; Sebago, Mooſehead, Willeguenguagun, and Chilmacook or Grand lake in Maine. The moſt important and uſeful harbours are thoſe of Machias, Frenchman's bay, Wiſcaſſet, Portland and Wells, in Maine; Piſcataqua in New Hampſhire; Newbury port, Salem, Marble head, Boſton, Provincetown, and New Bedford, in Maſſachuſetts Proper; Newport, Briſtol, and Providence, in Rhode iſland; and New London, New Haven, and Black rock, in Fairfield, in Connecticut. Burlington bay is the moſt conſiderable harbour in lake Champlain, on the Vermont ſhore.

The ſoil of New England is diverſified by every variety from a lean and barren ſand to the richeſt clays and loams. The hills are covered with a brown loam intermixed with gravel, which is favourable to the production of graſs, and in the weſtern parts of the country, of wheat, and all other kinds of grain and fruits ſuited to the climate. Clayey ſoils, when well manured, are very productive. A rich loam, varying towards clay, is prevalent in Connecticut, and is favourable to every kind of cultivation. Sand is generally found on the plains; and the yellow pine plains, which are commonly a mixture of ſand and gravel, are friendly to every production that does not require a richer ſoil. The white pine plains are uſually covered with loam, and theſe, as well as ſome of the laſt-mentioned in the ſame condition, are uncommonly fertile. The vallies are a rich mould; and the intervals, bordering the various ſtreams, are generally ſands formed by earth depoſited by the floods in the ſpring, and are of the richeſt quality.

New England, generally ſpeaking, is better adapted for grazing than for grain, though a ſufficient quantity of the latter is raiſed for home conſumption, if we except wheat which is largely imported, particularly into Maſſachuſetts, from the middle and ſouthern ſtates. Indian corn, rye, oats, barley, buck-wheat, flax and hemp, generally ſucceed very well. Fruits of every kind, which ſuit a temperate climate, may be obtained in abundance. The ſummer heat brings to perfection peaches, apricots, and nectarines. Orchards of apple-trees cover a conſiderable part of the whole country, and cyder is the common drink of the inhabitants. Pears, plums, cherries, currants, gooſeberries, whortleberries, blackberries, bilberries, &c. abound. Perry is made in ſome parts of the country, but not in great quantities. Various ſpecies of the hickery and hazle-nuts, and cheſnuts are plentifully furniſhed by the ſouthern half of New England. Gardening is much improved, and its productions are daily varying and increaſing. But the moſt important production of New England is graſs. The high and rocky ground is in many parts covered with clover, and affords excellent paſture to ſome of the fineſt cattle in the world. The quantity of butter and cheeſe made for exportation is very great. Conſiderable attention is now paid to the raiſing of ſheep; and the wool is in a ſtate of progreſſive improvement. The principal exports of New England are mackarel, ſalmon, cod, and other fiſh; whale-oil and whale-bone, timber, maſts, boards, ſtaves, hoops and ſhingles; horſes, mules, ſalted beef, and pork, pot-aſh, pearl-aſh, flax-ſeed, apples, cyder, corn, butter, and cheeſe. New England is the moſt populous part of the United States; it contained, in 1790, 1,009,522 perſons, and, in 1800, 1,233,011. The great body of the inhabitants conſiſts of landholders and cultivators of the ſoil. As they poſſeſs in fee-ſimple the farms which they cultivate, they are all naturally attached to their country; and the cultivation of the ſoil makes them robuſt and healthy. New England has been not unaptly denominated a nurſery of men; and hence are annually tranſplanted into other parts of the United States, thouſands of its natives. They are almoſt univerſally of Engliſh deſcent; and to this circumſtance, as well as to the general attention that has been paid to education, it is owing that the Engliſh language has been preſerved among them in ſo conſiderable a degree of purity. The New Englanders are generally tall, ſtout, and well-made. Their education, laws, and ſituation ſerve to inſpire them with high notions of liberty, of which they are jealous, in ſome caſes perhaps, to exceſs. A chief foundation of freedom in the New England ſtates is a law, by which inteſtate eſtates deſcend to all the children, or other heirs, in equal proportion; and hence it happens, that the people of New England enjoy an equality of condition, that is unknown in any other part of the world. Beſides, they are frugal and induſtrious, and inured to habits of ſobriety and temperance. Learning is more generally diffuſed among all ranks of people in New England than in any other part of the globe; which is owing to the excellent eſtabliſhment of ſchools in every town. In theſe ſchools, generally ſupported by a public tax, are taught the elements of reading, writing, and arithmetic; and in ſome of the principal and more wealthy towns they are purſuing education in a higher ſcale, and introducing the ſuperior branches of grammar, geography, and other ſciences. Literature is alſo encouraged and diffuſed by the circulation of newſpapers and periodical publications, and by the eſtabliſhment of reading ſocieties and parochial libraries. Curioſity, and a deſire of information, are very prevalent in New England; and the common people, it is ſaid, are diſtinguiſhed by attention and civility to ſtrangers. In former times the New Englanders were ſtrict, to a degree of punctiliouſneſs, in their obſervance of the ſabbath; and hence, as well as from ſome other traits of their character, they acquired the character of a ſuperſtitious and bigotted people. But ſince the war, a catholic, tolerant ſpirit, occaſioned by a more enlarged intercourſe with mankind, has much increaſed, and is becoming univerſal. "If," ſays Dr. Morſe, "they do not go beyond the proper bounds, and liberalize away all true religion, of which there is very great danger, they will counteract that ſtrong propenſity in human nature which leads men to vibrate from one extreme to its oppoſite." A cuſtom ſtill prevails, tranſmitted to the preſent race from their anceſtors, of annually celebrating faſts and thankſgivings. In ſpring, the governors of the ſeveral New England ſtates, Rhode iſland excepted, proclaim a day of faſting, humiliation, and prayer; and in autumn, after harveſt, they appoint a day of public thankſgiving. Many of the women in New England are handſome. Thoſe, who have enjoyed the advantages of a good education, and they are numerous, are genteel, eaſy, and agreeable in their manners, and are ſprightly and ſenſible in their converſation. And it is a laudable practice among the females to accuſtom themſelves at an early period to the management of domeſtic concerns with neatneſs and economy. Employment at the needle, in cookery, and at the ſpinning-wheel, is honourable. The women in country towns manufacture the greater part of the clothing of their families. Their linen and woollen cloths are ſtrong and decent. Among the amuſements of the people of New England is dancing, of which the young people of both ſexes are extremely fond. The athletic and healthy diverſions of cricket, foot-ball, quoits, wreſtling, jumping, hopping, foot-races, and priſon-bars, are univerſally practiſed in the country, and ſome of them in the moſt populous places, and by people of almoſt all ranks. Of the religion of the New Englanders, and of the proviſion that is made for the ſupport of it, we ſhall have occaſion to ſpeak under the article UNITED STATES. We ſhall here merely obſerve, that the conſtitution of theſe ſtates provides againſt the making of any law reſpecting an eſtabliſhment of religion, or prohibiting the free exerciſe of it. And in the conſtitution of the reſpective ſtates, religious liberty is a fundamental principle. Without the aid of civil power, religion is left to be ſupported by its own evidence, by the lives of its profeſſors, and the almighty care of its divine author. Its public teachers are maintained by an equal tax on property, by pew-rents, monies at intereſt, marriage and burial fees, ſmall glebes, land rents, and voluntary contributions. Chriſtians profeſs their religion under various forms, and with different ideas of its doctrines, ordinances, and precepts. Accordingly the ſects of Chriſtians are very numerous and various. Of theſe ſects, thoſe that are called Congregationaliſts are the moſt numerous. In New England there are about 1200 congregations of this denomination. Next to theſe in reſpect of number are Preſbyterians. In New England there are between 40 and 50 Proteſtant epiſcopal churches.

New England owes its firſt ſettlement to religious perſecution; and the inhabitants of this country are deſcended from thoſe that were called Puritans in the mother-country. The firſt attempt to form a regular ſettlement in this part of America was at Sagahadock in 1607; but in the following year, the whole number of thoſe who ſurvived the winter returned to England. The firſt company, that laid the foundation of the New England ſtates, planted themſelves at Plymouth, in November, 1620; though this appellation was given to North Virginia by Capt. Smith in Auguſt 1614. The founders of the colony conſiſted of 101 perſons. In 1640, the importation of ſettlers ceaſed, in conſequence of the abatement of perſecution by the change of affairs in England. At this time the number of emigrants, who had traverſed the ſeas in 298 veſſels, from the commencement of the colony, amounted to 21,200 men, women, and children, forming, perhaps, about 4000 families. In 1760, the number of inhabitants in Maſſachuſetts bay, New Hampſhire, Connecticut, and Rhode iſland, amounted, probably, to half a million. Morſe.

ENGLANTERIA, in *Botany.* See EGLANTERIA.

ENGLECHERIE, ENGLESCHERY, or *Engleſchyre*, a term of great import among our anceſtors, though now obſolete; properly ſignifying the quality of an Engliſhman.

If a man were privately ſlain or murdered, he was anciently accounted francigena (which comprehended every alien, eſpecially the Danes) till englecherie was proved, *i. e.* till it was made to appear that he was an Engliſhman. Bracton, lib. iii.

The origin of the cuſtom anciently ſubſiſting among the Goths in Sweden and Denmark, was thus: king Canutus, having conquered England, at the requeſt of his nobles, ſent back his army into Denmark, only reſerving a guard of Danes for his perſon; and made a law, that if any perſon was murdered, he ſhould be ſuppoſed to be a Dane, if he was not proved to be an Engliſhman by his parents or kindred, and, in default of ſuch proof, if the murderer was unknown, or had made his eſcape, the townſhip where the man was ſlain ſhould be charged to pay ſixty-ſix marks into the exchequer: or if by reaſon of the poverty of the townſhip, that ſum could not be raiſed from thence, it was to be paid by the hundred. After this law, which was continued by William the Conqueror, for the like ſecurity to his own Normans, whenever a murder was committed, it was neceſſary to prove the party ſlain an Engliſhman, that the penalty of ſixty-ſix marks might not be charged on the village. The manner of proving the perſon killed to be an Engliſhman was by two witneſſes, who knew the father and mother, before the coroner, &c. This practice was aboliſhed by ſtatute 14 Edw. III. cap. 4. See MURDER.

ENGLESQUEVILLE, in *Geography*, a ſmall town of France, in the department of the Lower Seine, 18 miles S.W. of Arques. There are ſeveral ſmall towns of the ſame name, in the department which compriſes the former province of Normandy.

ENGLISH, in a general ſenſe, ſomething that relates to the country or people of England. Thus we ſay, the Engliſh crown, Engliſh copperas, Engliſh names, Engliſh money, Engliſh meaſures, Engliſh weights, &c. The ſweating-ſickneſs is called by foreigners *ſudor Anglicanus*, the

Engliſh ſweat. (See Sudor-anglicus.) Dr. Cheyne calls the vapours the Engliſh malady.

English *Borough*. See Borough.

English *Cape*, in *Geography*, a cape on the ſouth coaſt of Newfoundland. N. lat. 46° 49′. W. long. 53° 29′.

English *Cove*, a harbour, or bay, on the coaſt of New Ireland, about 3 or 4 miles from cape St. George.

English *Drops*, *Guttæ Anglicanæ*. See Drop.

English *Harbour*, in *Geography*, one of the beſt harbours in the iſland of Antigua, ſituated on the S.W., a little to the E. of Falmouth harbour. It is well fortified, and has a royal navy-yard and arſenal, with conveniences for careening ſhips of war. N. lat. 17° 8′ 25″. W. long. 61° 27′ 30″.

English *Point*, a cape in the river St. Lawrence, on the coaſt of Canada. N. lat. 49° 40′. W. long. 61° 45′.

English *Reach*, a reach in the ſtraits of Magellan, about 3 leagues broad, between cape Gallant and cape Holland.

English *Road*, a road in the iſland of Eooa, or Middleburgh, in the South Pacific ocean, having 25 fathoms water. S. lat. 21° 20′. W. long. 174° 34′.

English *School of Engraving*. See Engraving.

English, or the English *Tongue*, the language ſpoken by the people of England; and with ſome variation, by thoſe of Scotland, as well as part of Ireland, and the reſt of the Britiſh dominions.

The Engliſh is of Gothic, or Teutonic extraction; this was the root or ſtock upon which ſeveral other dialects have been ſince grafted, particularly the Latin and French. See Teutonic, &c.

The language anciently ſpoken in our iſland was the Britiſh, or Welſh, which was common to the Britons and Gauls; and which ſtill ſubſiſts, in more or leſs purity, in the principality of Wales, the iſlands and Highlands of Scotland, part of Ireland, and ſome provinces of France, particularly Bretagne, and very lately ſubſiſted in the county of Cornwall. (See Cornish *Language*.) This language was the Celtic or Gaelic, which is ſaid to be very copious and expreſſive, and is, probably, one of the moſt ancient languages in the world. It once obtained in moſt of the weſtern regions of Europe: and now remains in the different dialects of the Iriſh, Welſh, and Erſe. See Celts.

As the Roman empire, extending itſelf towards the weſtern parts of Europe, under Julius Cæſar, Claudius, and Domitian, came to take in Gaul and Britain, the Roman tongue became propagated therewith; all the edicts, &c. relating to the public affairs, being deſignedly wrote in that language.

The Latin, however, it is certain, never got ſo much ground, or prevailed ſo far in England, as in Lombardy, Spain, and the Gauls; partly on account of its great diſtance from Rome, and the ſmall reſort of Romans hither; and partly, becauſe the entire reduction of the kingdom was not effected till ſo late as the reign of Claudius, when the empire was on the declining hand, and the new province was forced to be ſoon deſerted by its conquerors, called to defend their territories nearer home.

Britain, thus left naked, became an eaſy prey to the Angli, or Anglo-Saxons, a ſtrolling nation, from Jutland and Norway, who took an eaſy poſſeſſion thereof about the year 450, much about the time that the Franks, another German nation, entered Gaul. The Gauls and Franks, it ſeems, at length came to terms; found means to unite into one nation; and thus, the ancient Gauliſh, with its mixture of Latin, continued the prevailing tongue, only farther intermixed with the Francic or lingua Franca of the new inmates; but the Britons were more conſtant, and determined abſolutely to refuſe any ſuch coalition: they had embraced Chriſtianity, Auguſtine being ſent from Rome to convert them about the year 570, and their competitors were heathens; rather than admit of ſuch an union, they therefore choſe to be ſhut up, with their language, in the mountainous parts of Cambria or Wales.

The Engliſh Saxons, thus left abſolute lords, changed every thing; their own language, a dialect of the Gothic or Teutonic, and altogether diſtinct from the Celtic, was now fully eſtabliſhed, and laid the foundation of the preſent Engliſh tongue: and the very name of the country was henceforth to be Anglo-Saxon. (See Anglo-Saxon.) The new language remained, in good meaſure, pure and unmixed, till the Norman invaſion; the attempts of the Danes, and the neighbourhood of the Britons, indeed, wrought ſome leſſer innovations therein; but, in the main it preſerved itſelf; for, as to the Danes, their language was, probably, from the ſame root with the Saxon; and it did not long remain a diſtinct tongue in any part of England, but was blended with the Anglo-Saxon, and formed a particular dialect of that language.

This Dano-Saxonic dialect was principally ſpoken in the kingdom of Northumberland, where the Danes chiefly prevailed: that the Anglo-Saxon language was ſpoken in the S.E. parts of Scotland at this time is undeniable. When Edgar the Peaceable, king of England, yielded Lothian to Kenneth II. king of Scotland, A.D. 975, it was on theſe expreſs conditions; that the people of that country ſhould ſtill be called Engliſhmen, be governed by the Engliſh laws, and be allowed to ſpeak the Engliſh language.

Edward the Confeſſor, however, who had lived long in France, might poſſibly bring in a little mixture of the dialect of that country.

But William I. and his Normans, having got poſſeſſion of England, an alteration was ſoon attempted: the conqueſt was not complete, unleſs the Conqueror's language, the French and Franco-Gallic, were introduced; and accordingly all his acts, diplomas, edicts, pleadings, and other judicial matters, were written, &c. in that tongue.

But his attempts proved unſucceſsful; the number of Normans he brought over being very ſmall in compariſon of the Engliſh, with whom they were incorporated, they loſt or forgot their own language, ſooner than they could make any change in the Engliſh. This, however, did not hinder, but, by the endeavours of the Conqueror, abundance of French words, though many of them of Latin original, crept into the Engliſh; and many Engliſh words, by degrees, grew out of uſe. Hence it happened, that the Engliſh, which was ſpoken afterwards, and continues to be ſpoken now, is a mixture of the ancient Saxon and this Norman French, together with ſuch new and foreign words as commerce and learning have in the progreſs of time gradually introduced. See Anglo-Saxon.

Upon the whole it appears, that the Teutonic dialect is the baſis of our preſent ſpeech. It has been imported among us in three different forms, the Saxon, the Daniſh, and the Norman; all which have mingled together in our language, ſo that it may be ſuppoſed to exiſt in three different periods, *viz.* Anglo-Saxon, Daniſh-Saxon, and Norman-Saxon. The firſt begins with the Saxon invaſion, the ſecond with the Daniſh, and the third with the Norman. Some have made the properly Engliſh period to commence with Edward I., towards the cloſe of the 13th century; others have referred it to the 14th century; and others again have thought that it ought rather to commence with Henry VIII.; as the controverſies of the Reformation were in fact the cauſe which then aboliſhed the Norman dialect of the court, and introduced the preſent common Engliſh to our worſhip and to our literature. Many of our words are alſo plainly derived from the Latin. But theſe were not introduced directly from the Latin; whereas moſt of them, probably, entered into our tongue through the channel of that Norman French, which William the Conqueror introduced. For, as the Romans had long been in full poſſeſſion of Gaul, the language ſpoken in that country, when it was invaded by the Franks and Normans, was a ſort of corrupted Latin, mingled with Celtic, to which was given the name of Romanſh; and as the Franks and Normans did not, like the Saxons in England, expel the inhabitants, but, after their victories, mingled with them; the language of the country became a compound of the Teutonic dialect imported by theſe conquerors, and of the former corrupted Latin. Hence, the French language has always continued to have a very conſiderable affinity with the Latin; and hence, a great number of words of Latin origin, which were in uſe among the Normans in France, were introduced into our tongue at the conqueſt: to which, indeed, many have been ſince added, directly from the Latin, in conſequence of the great diffuſion of Roman literature throughout all Europe. From the influx of ſo many ſtreams, or the junction of ſo many diſſimilar parts, it naturally follows that the Engliſh, like every compounded language, muſt neceſſarily be ſomewhat irregular. We cannot expect from it, ſays Dr. Blair (Lectures, &c. vol. i.) that correſpondence of parts, that complete analogy in ſtructure, which may be found in thoſe ſimpler languages, which have been formed in a manner within themſelves, and built on one foundation. Hence, it has but ſmall remains of conjugation or declenſion; and its ſyntax is narrow, as there are few marks in the words themſelves that can ſhew their relation to each other, or, in the grammatical ſtyle, point out either their concordance, or their government, in the ſentence. Our words having been brought to us from ſeveral different regions, ſtraggle, if we may ſo ſpeak, aſunder from each other; and do not coaleſce ſo naturally in the ſtructure of a ſentence, as the words in the Greek and Roman tongues. But theſe diſadvantages, if they be ſuch, of a compound language, are balanced by other advantages that attend it; particularly by the number and variety of words with which ſuch a language is likely to be enriched.

As to the origin and etymology of many of our words, Dr. Wallis lays it down, that ſuch words of German original as we have, in common with the French, are to be reckoned as our own, rather than as words borrowed from them; and that the old Gauliſh words, common to the French and the Welſh, which are found in our language, have been likewiſe taken from the Welſh, rather than from the French. Hence, alſo, the ſame author accounts why the names of the divers ſorts of cattle are Saxon; as ox, cow, calf, ſheep, hog, boar, deer, &c. and yet that their fleſh, when prepared for food, is French; as beef, veal, mutton, pork, brawn, veniſon, &c. the Norman ſoldiers not concerning themſelves with paſtures, parks, and the like places, where ſuch creatures are fed and kept, ſo much as with markets, kitchens, feaſts, and entertainments, where the food was either prepared, ſold, or eaten.

Under Henry II., Dr. Swift obſerves, the French made a ſtill greater progreſs; becauſe of the large territories he poſſeſſed on that continent, both from his father and his wife, which occaſioned frequent journies thither, with numerous retinues, &c. And for ſome centuries after, there was a conſtant intercourſe between France and England, by the dominions we poſſeſſed there, and the conqueſts we made; ſo that the language, two or three hundred years ago, ſeems to have had much more French than at preſent.

Beſides this alteration from the conquerors, the language in proceſs of time underwent ſeveral others; and at length came to have numerous words and phraſes of foreign dialects ingrafted into it, in lieu of the ancient Saxon; particularly, by means of negociations and commerce with other nations; by the marriages of royal families; by the affectation of many writers, in moſt ages, who are fond of coining new words, and altering the uſual forms of ſpeech, for the greater delicacy; and, by the neceſſity of framing or borrowing new words, according as new things and inventions turn up: and by ſuch means was the old Anglo-Saxon converted into the preſent Engliſh tongue. See ANGLO-SAXON.

Having traced the riſe and progreſs of our language hiſtorically, we think it may be no incurious amuſement to repreſent by actual examples the ſeveral ſucceſſive changes and ſtages it has paſſed through, to arrive at its preſent perfection: in order to which, we ſhall make uſe of the collections of the ingenious Mr. Greenwood.

From the Saxon invaſion, we have no memorial extant of the language for 250 years: the oldeſt Saxon writing in being is a gloſs on the evangeliſts, written in the year 700, by Eadfride, biſhop of Holy Iſland; in which the three firſt articles of the Lord's Prayer run thus:

"Uren Fader thic arth in heofnas, ſic gehalgud thin noma, to cymeth thin ryc. Sic thin willa ſue is in heofnas, and in eortho," &c. See ANGLO-SAXON.

Two hundred years after, in the year 900, the ſame was rendered thus:

"Thu ure Fader the eart on heofinum, ſi thin nama gehalgod; cum thin ric. Si thin willa on eorthan ſwa, ſwa on heofinum."

In the following age it was turned thus in the Saxon Homilies, ſaid to be tranſlated by king Alfred:

"Fæder ure thu the earth on heofenum, ſi thin nama gehalgod, to be cume thin rice, gewurthe thin willa on eoarthan ſwa, ſwa on heofnum," &c.

About the year 1160, under Henry II., near which period the Saxon began to aſſume a form in which the beginning of the preſent Engliſh may be diſcovered; it was thus rendered by pope Adrian, an Engliſhman, in rhyme:

"Ure Fader in heaven rich,
Thy name be hayled ever lich,
Thou bring us thy michell bliſſe:
Als hit in heaven y-doe
Evar in yearth beene it alſo," &c.

About 100 years after, in the time of Henry III., it was tranſlated thus:

"Fadir that art in heaven bliſſe,
Thin helge nam it wurth the bliſs,
Cumen & mot thy kingdom,
Thin holy will be it all don,
In heaven and in erdh alſo," &c.

Two hundred years after, under Henry VI., it was rendered thus:

"Our Fadir that art in hevenes, halewid be the name, thi kingdom come to thee, be thi will don in eerthe, as in hevene."

Dr. Hickes furniſhes an extraordinary ſpecimen of the Engliſh, as ſpoken in the year 1385, in his Theſaur. Liter. Septent. which we ſhall the rather amuſe the reader with, as it is on this very ſubject, the Engliſh tongue; and contains not only the hiſtory, but the reaſon of the changes and differences therein:

"As it is knowe how meny maner peple beeth in this lond; there beeth alſo ſo many dyvers longages and tonges. Notheleſs Walſche men and Scots that beeth nought medled with other nations, holdeth wel nyh hir firſt longage and ſpeche: but yif the Scottes that were ſometime confederat and woned with the Pictes drawe ſomewhat after hir ſpeche; but the Flemynges that woneth in the weſte ſide of Wales, haveth left her ſtrange ſpech, and ſpeketh Sexonliche now. Alſo Engliſhe men, they had from the bygynnynge thre maner ſpeche; northerne, ſowtherne, and middel ſpeche in the middel of the londe, as they come of three maner of peple of Germania: notheleſs by commyxtion and mellynge firſt with Danes, and afterwards with Normans, in meny the contrary longage is apayred [corrupted.] This appayrynge of the burthe of the tunge is bycauſe of tweie thynges, oon is for children in ſcole agenſt the uſage and maner of all other nations, beeth compelled for to leve hire own longage, and for to conſtrue hir leſſons and here thynges in French, and ſo they haveth ſethe Normans come firſt into Engelond. Alſo gentlemen children beeth taught to ſpeke Frenſche from the tyme that they beeth rokked in here cradel, and kunneth ſpeke and play with a childes broche; and uplondiſſche men will linke hymſelf to gentilmen, and fondeth with great beſyneſſe for to ſpeake Frenſche to be told of. Hit ſeemeth a greet wonder how Engliſche men and her own longage and tonge, is ſo dyverſe of ſown in this oon ilond; and the longage of Normandie is comlynge of another lond, and hath oon manner ſoun amonge alle men that ſpeketh hit arigt in Engelond. Alſo of the foreſaid Saxon tonge that is deled [divided] a three, and is abide ſcarceliche with few uplondiſſche men, is greet wonder. For men of the eſt, with men of the weſt, is, as it were, under the ſame partie of hevene acordeth more in ſownygne of ſpeech, than men of the north, with men of the ſouth. Therefore it is that Mercii, that beeth men of myddel Engelond, as it were parteners of the endes, underſtondeth bettre the ſide longages northerne and ſoutherne, than northerne and ſoutherne underſtondeth either other. All the longage of the Northumbers, and ſpecialliche at York, is ſo ſcharp, ſlitting and frotynge, and unſchape, that we ſoutherne men may that longage unnethe underſtonde. I trow that that is by cauſe that they beeth nyh to ſtrange men and nations, that ſpeketh ſtrongliche, and alſo bycauſe that the kinges of Engelond wonneth alwey fer from that cuntry," &c.

The firſt of our authors, who can properly be ſaid to have written Engliſh, was ſir John Gower, who, in his Confeſſion of a Lover, calls Chaucer his diſciple.

How the Engliſh ſtood about the year 1400, may be ſeen in Chaucer, who refined and improved it very conſiderably; though he is charged with the affectation of mixing too many French and Latin words with his Engliſh, and by that means, with too much altering and corrupting the primitive language.

In the year 1537, the Lord's Prayer was printed according to the following verſion:

"O oure Father which arte in heven, halowed be thy name: let thy kingdome come, thy will be fulfiled as well in erth as it is in heven," &c.

Where the reader will obſerve the diction almoſt brought to the preſent ſtandard; the variations being principally in the orthography. See an hiſtorical view of the progreſs of the Engliſh language, with ſpecimens at different periods, from the age of Alfred to that of Elizabeth, in the Introduction to Dr. Johnſon's Engliſh Dictionary, vol. i. fol.

Spencer, who lived in the ſame age, contributed not a little to the improvement and refining of the tongue: he threw aſide abundance of the outlandiſh ornaments, and wrote a purer Engliſh, yet with more elegance and variety than had been known before. He was ſucceeded by Shakeſpeare, Ben. Johnſon, lord Bacon, Milton, Cowley, Waller, Tillotſon, Dryden, Addiſon, and Pope, &c. whoſe works are in every body's hands; and by whom the language has been tranſmitted to us under all its preſent advantages.

The perfections aſcribed to the Engliſh, and alſo in a degree ſuperior to any of the modern tongues, are, 1. That it is very ſtrong and ſignificant; to which our finely compounded words, formed on the model of the Greeks, do not a little contribute.

This may alſo be partly aſcribed to the national character of the people who ſpeak it, from which language is apt to receive its predominant tincture. Thus, the gravity and thoughtfulneſs, as well as the ſtrength and energy, of the Engliſh, and alſo the gaiety and vivacity of the French, are ſufficiently impreſſed on their native tongues. However, though the Engliſh language poſſeſſes diſtinguiſhing ſtrength and energy, it is naturally prolix, on account of the great number of particles and auxiliary verbs, which in the uſe of it we are obliged conſtantly to employ; and this prolixity muſt, in ſome degree, enfeeble it. We ſeldom can expreſs ſo much by one word as was done by the verbs, and by the nouns, in the Greek and Roman languages. Our ſtyle is leſs compact; our conceptions being ſpread out among more words, and ſplit, as it were, into more parts, make a fainter impreſſion when we utter them. Notwithſtanding this defect, as our language abounds in terms for expreſſing all the ſtrong emotions of the mind, and we have the liberty, in a greater degree than moſt nations, of compounding words, it may be eſteemed to poſſeſs conſiderable force of expreſſion; more eſpecially when we compare it with the other modern tongues, though much below the ancient. The ſtyle of Milton alone, both in poetry and proſe, affords ſufficient evidence, that the Engliſh tongue is far from being deſtitute of nerves and energy.

2. The Engliſh language is copious; of which Mr. Greenwood gives us inſtances in the word ſtriking; which we have above thirty different ſynonymous expreſſions for; as *to ſmite*, *bang*, *beat*, *baſt*, *buffet*, *cuff*, *hit*, *thump*, *thwack*, *ſlap*, *rap*, *tap*, *kick*, *ſpurn*, *box*, *yerke*, *pummel*, *punch*, &c. and the word *anger*, for which he enumerates above forty. So we ſay *to ſeeth* or *boil* fleſh, *ſtew* prunes, *poche* eggs, *coddle* apples, *bake* bread; for which expreſſions, *to ſeeth*, *ſtew*, *poche*, *coddle*, and *bake*, the Latins, with all the boaſted copia of the tongue, have only one word, *coquere*; and the French, as much as they abound with terms of cookery, not many more; the word *cuire* ſerving indifferently for *ſeething*, *boiling*, *baking*, *ſtewing*, and *codling*.

Indeed, few languages are more copious than the Engliſh. In all grave ſubjects eſpecially, hiſtorical, critical, political, and moral, no writer can juſtly complain of the barrenneſs of our tongue. We are alſo rich in the language of poetry. Our poetical ſtyle differs widely from proſe, not in point of numbers only, but in the very words themſelves; which ſhews what a ſtock and compaſs of words we may ſelect and employ, ſuited to different occaſions. In this reſpect we are infinitely ſuperior to the French, whoſe poetical language, if it were not diſtinguiſhed by rhyme, would not be known to differ from their ordinary proſe. It is chiefly, however, on grave ſubjects, and with reſpect to the ſtronger emotions of the mind, that our language diſplays its power of expreſſion. But, in deſcribing the more delicate ſentiments and emotions, our tongue is not ſo fertile; and we muſt acknowledge its inferiority to the French. This is, perhaps, the happieſt language for converſation in the known world; but, on the higher ſubjects of compoſition, it is much excelled by the Engliſh.

3. The Engliſh language is not deſtitute of flexibility, This power of accommodation to different ſtyles and manners, ſo as to be either grave and ſtrong, or eaſy and flowing, or tender and gentle, or pompous and magnificent, as an author's genius prompts or occaſions require, is a quality of great importance both in ſpeaking and writing. This property of a language ſeems to depend upon three things: its copiouſneſs; the different arrangements of which its words are ſuſceptible; and the variety and beauty of the ſound of thoſe words, ſo as to correſpond to many different ſubjects. The Greek poſſeſſed this property in a ſupereminent degree; the Latin was, in this reſpect, inferior to it; and among the modern tongues, the Italian poſſeſſes flexibility in a greater degree than the French; and though our language has leſs of it than the Italian, it poſſeſſes a conſiderable degree of this quality. If any one will conſider the diverſity of ſtyle which appears in ſome of our claſſics; that great difference of manner, for inſtance, which is marked by the ſtyle of lord Shafteſbury, and that of dean Swift; he will perceive, in our tongue, ſuch a circle of expreſſion, ſuch a power of accommodation to the different taſte of writers, as redounds not a little to its honour.

4. Some have challenged to the Engliſh language the praiſe of being muſical and harmonious; and in this reſpect Mr. Dennis makes no ſcruple to aſſert it ſuperior even to the French. This, which ſome may think ſtrange, he proves hence, that we have blank verſe which is harmonious by mere force of numbers and quantity; whereas the French have long ago deſiſted from all pretenſions to poetical numbers, without the aſſiſtance of rhyme.

It may be added on this laſt head, from Mr. Welſtead, that the Engliſh has many meaſures, the iambic and trochee, for inſtance, in common with the Greek and Latin; an advantage ariſing from the variation of the accent; and that rhyme is peculiarly natural to it, varying itſelf to the ear with exceſſive ſweetneſs; not to mention the cæſuras, pauſes, tranſpoſitions, and numberleſs other graces, which the Engliſh verſification is capable of, probably beyond every other living language.

The Engliſh has, indeed, been reproached on account of its deficiency in harmony of ſound; but the charge has been extended too far. The melody of our verſification, and the power which our language poſſeſſes of ſupporting poetical numbers, without any aſſiſtance from rhyme, afford ſufficient proof that our language is far from being unmuſical. Next to the Italian, our verſe is the moſt diverſified and harmonious of any of the modern dialects; and far exceeds the French in variety, ſweetneſs, and melody. Mr. Sheridan has ſhewn, in his Lectures, that we abound more in vowel and diphthong ſounds than moſt languages; and theſe, too, ſo divided into long and ſhort, as to afford a proper diverſity in the quantity of our ſyllables. Our conſonants, he obſerves, though they appear crowded to the eye on paper, often form combinations not diſagreeable to the ear in pronouncing; and, in particular, the objection which has been made to the frequent recurrence of the hiſſing conſonant *s* in our language is unjuſt and ill-founded: for this letter frequently loſes the hiſſing ſound, eſpecially in the final ſyllables, and is transformed into a *z*, affording a ſound on which the ear can reſt with pleaſure. After all, it muſt be allowed, that ſtrength and expreſſiveneſs, more than grace and melody, are the diſtinguiſhing properties of the Engliſh tongue. It is a remarkable peculiarity of Engliſh pronunciation, that the accent is thrown farther back, or nearer the beginning of a word, than is done by any other nation; and the general effect of this practice of haſtening the accent is to give a briſk and a ſpirited, but at the ſame time a rapid and hurried, and not very muſical, tone to the whole pronunciation of a people.

5. The Engliſh tongue is, without doubt, the moſt ſimple in its form and conſtruction of all the European dialects. It is free from all intricacy of caſes, declenſions, moods, and tenſes. The words are ſubject to fewer variations from their original form than thoſe of any other language. Its ſubſtantives have no diſtinction of gender, except what nature has made, and but one variation in caſe. Its adjectives admit of no change at all, except what expreſſes the degree of compariſon. Its verbs, inſtead of running through all the varieties of ancient conjugation, ſuffer no more than four or five changes in termination. By the help of a few prepoſitions and auxiliary verbs, all the purpoſes of ſignificancy in meaning are accompliſhed; while the words commonly preſerve their form unchanged; which ſtructure, though it has its diſadvantages in point of elegance, brevity, and force, contributes to facility. However, biſhop Lowth has obſerved in the Preface to his Grammar, that the ſimplicity and facility of our language occaſion its being frequently written and ſpoken with leſs accuracy. See GRAMMAR, LANGUAGE, STYLE, SYNTAX, &c.

Some object to the Engliſh, that it conſiſts too much of monoſyllables; which others repreſent as an excellence, becauſe it argues a greater antiquity, if what Salmaſius ſays be true: Certum quippe eſt, linguas omnes, quæ monoſyllabis conſtant, cæteris eſſe antiquiores;" he adds, that the "ancient Greek abounded herein, as appears from the ancient poets, and ſuch as affected antiquity." De Re Helleniſt.

But we have a farther advantage from our monoſyllables, *viz.* "conciſeneſs;" as we are hereby enabled to expreſs more matter in the ſame compaſs of letters than any other modern tongue. The only thing we ſuffer by it, is, ſomething in point of ſoftneſs and numbers; and yet we have verſes compoſed wholly of monoſyllables, that do not want harmony; as that of Creech,

> "Nor could the world have borne ſo fierce a flame."

Others object to our language, that it does not equal the ſoftneſs, the delicacy, of the more ſouthern languages, of France, Spain, and Italy. It ſeems to retain ſomewhat of the Gothic roughneſs of the people who framed and introduced it; the ſoil and climate it was planted in, not tending much to mellow and refine it.

To this purpoſe does Dr. Swift ſpeak, who accounts for the effect hence, that the Latin tongue was never in its purity in our iſland; and beſides, it was removed, in its imperfect ſtate, before it could have time to incorporate with the language of the country, and ſubdue and ſoften it, as it did in the other provinces of France and Spain, &c. But it is to be obſerved, that, upon the whole, this, ſuppoſing it true, does not lie as an objection againſt the language, but the people: our manners are alſo leſs poliſhed than ſome of our neighbours; we are not yet arrived at that pitch of moleſſe, of delicateſſe, of ſoupleſſe, which we cenſure in them; and it is but juſt our language correſpond with the reſt of our character.

Mr. Welſtead is of opinion, that the Engliſh language is not capable of a much greater perfection than it has already attained. We have trafficked, he obſerves, with every country for the enriching of it; the ancients and moderns have both contributed to give it ſplendour and magnificence; the faireſt cyons that could be had from the gardens of France and Italy, have been grafted on our old ſtocks, to refine the ſavageneſs of the breed; we have laid aſide moſt of our harſh, antique words, and retained few but thoſe of good and ſound energy: the moſt beautiful poliſh is at length given to our tongue that it will bear, without deſtroying and altering the very baſis and ground work of it; its Teutonic ruſt is worn away, and little or nothing is wanting either of copiouſneſs or harmony. He goes on to argue the maturity and perfection of the Engliſh, from another very extrinſic principle, *viz.* by comparing the time and circumſtances of the improvements made ſince the firſt refiners of it; with thoſe of the Greek, Latin, French, and other tongues that confeſſedly have riſen to their height.

Every civilized nation, that author thinks, has its claſſical age; and he ſuggeſts, that the Engliſh are not far from it. So that what remains to be done for the Engliſh tongue, ſhould not be to advance, but to fix it where it is, and prevent its declining. There is, in effect, a point of perfection, which when a language has once arrived at, it cannot exceed, though it may degenerate from it; and thus it happened to the two fineſt languages that the world has known.

It may ſeem odd to talk of fixing ſo unſtable a thing as language: the Greek liturgies of St. Baſil, and St. Chryſoſtom, ſtill uſed in that church, the one for ſolemn, the other for common days, have been a long time unintelligible to the people; ſo much has the vulgar Greek degenerated from its original purity! Polybius teſtifies, that the articles of truce between the Romans and Carthaginians could ſcarcely be underſtood by the moſt learned Roman antiquaries, three hundred and fifty years after the time in which they were made. In effect, from the days of Romulus to thoſe of Julius Cæſar, the Latin was perpetually changing; and what was written three hundred years before Tully, was as unintelligible in his time as the Engliſh and French of the ſame period are now; and theſe two have changed as much ſince William the Conqueror, in about eight hundred years, as the Latin appears to have done in a like term.

Whether our language will decline as faſt as the Roman did, may admit of ſome doubt; there being many circumſtances in the affairs of the nation, which contributed to that ſpeedy corruption, that may not, in all probability, find place among us. The French for about two centuries paſt, has been poliſhing as much as it will bear; and it appears to be now declining, by the natural inconſtancy of that people, and the affectation of ſome late authors, to introduce cant words, which is the moſt ruinous corruption in any language. But without ſome ſuch conſideration there does not ſeem any abſolute neceſſity, why a language ſhould be perpetually changing.

We find examples to the contrary: from Homer to Plutarch, are above a thouſand years; and ſo long, at leaſt, Dr. Swift thinks, we may allow the purity of the Greek; the Grecians ſpread their colonies round all the coaſts and iſlands of Aſia Minor, and the Ægean ſea, where the language was preſerved entire for many ages after they themſelves became provinces to Rome, and were over-run by the barbarous nations. The Chineſe have books in their language above two thouſand years old; neither have the frequent conqueſts of the Tartars been able to alter it. And the German, Spaniſh, and Italian, have admitted few or no changes for ſome ages paſt.

On ſuch conſiderations, that author moved the then prime miniſter, the earl of Oxford, to eſtabliſh a ſociety, or academy, for the ſettling, and aſcertaining, the purity of our tongue; to ſet a mark on the improprieties which cuſtom has made familiar, to throw out vicious phraſes and words, to correct others, and perhaps retrieve ſome others now grown obſolete, and to adjuſt the orthography, pointing, &c.

Without ſome ſuch means, he complains that the fame any writer can expect will be ſo ſhort and ſcanty, as by no means to be a ſufficient motive to call forth, and engage a man to exert his genius. Our language is chiefly confined to theſe two iſlands; and it is hard our authors' fame ſhould be limited in time as well as place. Were it not for the Bible and Common-Prayer, we ſhould hardly have been able to underſtand any thing written about two centuries ago.

It is a melancholy reflection, that Petrarch ſtill ſpeaks good Italian; whereas Chaucer, who lived an hundred years later, is not to be underſtood by an Engliſh reader without a Saxon and French gloſſary. And what ſecurity has Dryden himſelf, while things continue on their preſent footing, that he ſhall not, in a like ſpace of time, become as obſolete as Chaucer is?

Grammars and dictionaries, with whatever care and judgment they are compoſed, will prove but a feeble ſtay to a fleeting language, unleſs they have ſome extraordinary ſanction and authority. And, what is to be lamented, ſuch writings have contributed to the corruption almoſt as much as the perfection of our tongue.

Dr. Gill, Ben Johnſon, and Hexham, it is certain, by forcing the Engliſh tongue to the Latin method, have clogged and perplexed it with abundance of uſeleſs precepts concerning caſes, genders, and declenſion of nouns, tenſes, moods, and conjugations of verbs, and other things which our language has nothing to do with. Nor have even Dr. Wallis, Greenwood, &c. though ſenſible of the fault in thoſe others, been able wholly to keep clear of it themſelves. See STYLE.

ENGLISH *Town*, in *Geography*, a ſmall village in the north-weſtern part of Monmouth county, in New Jerſey, on the road from Princeton to Shrewſbury; 21 miles from the former, and ſix W. of Monmouth court-houſe.

ENGLISH *Turn.* See DETOUR *Des Anglois.*

ENGLSTAIN, a town of Germany, in the archduchy of Auſtria; ſix miles N.W. of Zwetl.

ENGONASIS,, Εγγονασις, in *Aſtronomy*, Hercules; one of the northern conſtellations. See HERCULES.

ENGOUTED, in *Falconry*, is ſaid of a hawk's feathers, when they have black ſpots in them.

ENGRAFTING. See GRAFTING.

ENGRAILED, or INGRAILED, in *Heraldry*, (from the French *grêle*, hail) is when a thing is repreſented with its edges ragged, or notched, ſemi-circularly, as if broken by ſomething falling on it. See INDENTED and INVECTED.

Spelman expreſſes it in Latin by *imbricatus;* others by *ingrediatus;* and others by *ſtriatus.*

ENGRAPPLE. This is a device in uſe principally in *Naval Warfare*, where it is intended to retain an enemy's veſſel in ſome particular poſition, eſpecially for the purpoſe of boarding. When an opportunity may offer of grappling acroſs a ſhip's bows, or ſtern, ſo as to allow raking her fore and aft, the battle is uſually but of ſhort duration; it being almoſt impoſſible for a crew to ſtand to their guns while ſubject to ſo deſtructive a fire. Generally we find, that when a commander is intent on boarding his opponent, he has his yard-arms ſupplied with ſmall grapnails, which being lowered down at pleaſure, among the enemy's rigging, hook therein, and thus prevent her from retiring to avoid the boarders. Sometimes poles, having long barbs at their ends, are uſed for the ſame purpoſe; theſe are chiefly managed by the forecaſtle-men, and have their butts laſhed to the *davit*, or to the *cat-head*. Whatever contrivance may be in uſe for engrappling, it is expedient that the implement be every where ſufficiently ſolid or firm to retain its hold, and to reſiſt the hatchet, otherwiſe the enemy would ſpeedily cut them away: thus, all grap-nails ſhould be ſuſpended by means of chains, paſſed through blocks at the yard-arms; nor ſhould the tackle, by which they are acted upon, be hauled tight until the points of the grap-nails may be firmly hooked among the ſhrowd-hawſers, or ſome ſuch ſubſtantial part of the enemy's rigging, which he could not, with ſafety to his maſts or yards, cut away. Where it is practicable, a very ſtrong chain ſhould be paſſed round the whole of the ſhrowd-hawſers of that maſt, reſpectively, oppoſite which the veſſel is engrappled; or, if that be too hazardous, the chain-plates may be ſecured in a ſimilar manner. It is evident, that were the former to be all included, the enemy muſt cut away every ſupport on that ſide his maſt, before he could extricate himſelf; in the latter inſtance, as the chain-plates are of iron, and very ſubſtantial, nothing but the chain, whereby they are embraced, giving way, could afford the means of ſeparation.

Sometimes ſhips become fortuitouſly engrappled, by the flukes of their anchors hooking among the rigging of the veſſels oppoſed to them: this, however, is ſeldom permanent; for as the engrappling ariſes from accident, ſo does a lift, or heave of the ſea, ordinarily ſet the parties at liberty, either by tearing away whatever hitches upon the fluke, or by cauſing the latter to unhook itſelf. Where the ſea runs high, this is often the caſe; expoſing both veſſels to the moſt imminent danger, and always cauſing conſiderable damage. Hence, it ſhould ever be conſidered by a commander, how far the ſafety of his ſhip may become queſtionable in the attempt to approach his opponent, when there is much ſwell. The practice of engrappling is, indeed, but rarely reſorted to in ſhips of the line, or even by frigates; but is extremely common among privateers abounding in men, and intent upon bringing an engagement to a very ſpeedy iſſue, ſo as to ſave their hulls and rigging from ſuch damages as might compel them to ſeek a port wherein to re-fit.

ENGRAVER, one who practiſes the art of engraving. See Engraving.

Engraver's *Act*, the act for ſecuring the copy-right of engraved prints. That engravers might enjoy the fair advantages ariſing from the exerciſe of their own talents, and that the public at large might in due time ſucceed to ſuch advantages, an act of parliament was paſſed in the 8th year of Geo. II., "for the encouragement of the arts of deſigning, engraving, and etching hiſtorical and other prints, by veſting the properties thereof in the inventors and engravers, during a time therein mentioned."

After thus veſting the property for the term of *fourteen* years, to commence from *the day* of publication, it enacts that the name of the proprietor ſhall be engraved on each plate; "and any printſeller, or other perſon, who ſhall engrave, etch, or in any other manner copy, and ſell, or cauſe to be engraved, etched, or copied and ſold, in the whole or in part by varying, adding to or diminiſhing from the main deſign, or ſhall print, reprint, or import for ſale any ſuch print or prints, "without the conſent of the proprietor firſt had and obtained in writing," ſigned by him in the preſence of two credible witneſſes, or knowing the ſame to be ſo printed, &c. without conſent of the proprietor, ſhall publiſh, ſell, or expoſe to ſale, then ſuch offender "ſhall forfeit the plate or plates" on which ſuch print or prints are or ſhall be copied, and all and every ſheet or ſheets (being part of or whereon ſuch print or prints are or ſhall be ſo copied or printed) "to the proprietor or proprietors of ſuch original print or prints," who ſhall forthwith deſtroy the ſame. And further, that every ſuch offender ſhall forfeit five ſhillings for every print which ſhall be found in his cuſtody, either printed and publiſhed, or expoſed to ſale; one moiety to the king and the other to the informer.—*Note*, Theſe penalties do not extend to purchaſers of plates from the original proprietors (ſ. 2.): and actions for offending againſt this act muſt be brought within three months (ſ. 3.)

The act of 7 Geo. III. c. 38. after reciting that the preceding act had been found ineffectual, enacts, that the original inventors, deſigners, or engravers of any print, "map, chart, or plan, or any other print whatſoever," taken from any picture, drawing, or ſculpture, are entitled to the benefit and protection of the recited and preſent acts; and by (ſect. 7,) *extends* the rights intended to be ſecured by this and the former act to the term of *twenty-eight* years.

A ſubſequent act (paſſed in the 17th of Geo. III.) ſtates, that the former acts have not anſwered the purpoſes for which they were intended, and that it is neceſſary for the encouragement of artiſts, that further proviſions ſhall be made. It therefore enacts, that if any engraver, etcher, printſeller, or other perſon, ſhall, within the time limited by the aforeſaid acts, engrave or etch, or cauſe, or procure to be engraved or etched, or worked, in "mezzotinto, or chiaro-ſcuro, or otherwiſe," copy; or who ſhall print, re-print, or import for ſale, any copy of any hiſtorical print, or any portrait, converſation, landſcape, or architecture, map, chart, or plan, or any other print whatſoever, which hath, or have been, or ſhall be engraved, etched, drawn, or deſigned "in any part of Great Britain," without the expreſs conſent of the proprietors firſt had and obtained in writing, then every ſuch proprietor ſhall and may in a ſpecial action on the caſe to be brought againſt the offending party, recover *ſuch* damages *as a jury* on the trial of ſuch action, upon the execution of a writ of enquiry thereon, "ſhall give or aſſeſs," together with "double coſts of ſuit."

The following are the moſt important caſes which have ſubſequently occurred, and which are introduced to ſhew the legal conſtruction which has been put upon the aforeſaid act of parliament, by magiſtrates of high authority.

In the ſittings after Hilary term, 25 Geo. III. before lord chief juſtice Manſfield, Sayer brought an action againſt Moore for pirating ſea charts. The charts which had been copied were four in number, which Moore had made into one large map. It appeared in evidence that the defendant had taken the body of his publication from that of the plaintiff; and that the plaintiff had originally been at great expence in procuring materials for theſe maps; but it was alſo proved that the defendant had made many material alterations and improvements thereupon. Lord Manſfield's addreſs to the jury upon this occaſion is remarkable and important. "The rule of deciſion in this caſe, he obſerved, is a matter of great conſequence to the country: in deciding it we muſt take care to guard againſt two extremes equally prejudicial; the one, that men of ability who have employed their time for the ſervice of the community, may not be deprived of their juſt merits, and the reward of their ingenuity and labour: the other, that the world may not be deprived of improvement, nor the progreſs of the arts be retarded: the act that ſecures copy-right to authors, guards againſt the piracy of the words and ſentiments; but it does not prohibit writing upon the ſame ſubject, as in the caſes of hiſtories and dictionaries: in the firſt a man may give a relation of the ſame fact, and in the ſame order of time; in the latter an interpretation is given of the identical words: in all theſe caſes, the queſtion of fact to come before a jury, is whether the alteration be colourable or not; there muſt be ſuch a ſimilitude as to make it probable and reaſonable to ſuppoſe that one is a tranſcript of the other; ſo in the caſe of prints, no doubt different men may take different engravings from the ſame picture. The ſame principle holds with regard to charts: whoever has it in his intention to publiſh a chart, may take advantage of all prior publications; there is no monopoly of the ſubject here, any more than in the other inſtances, but upon any queſtion of this nature the jury will decide whether it be a ſervile imitation or not. If an erroneous chart be made, God forbid it ſhould not be corrected, ſince it thereby becomes more ſerviceable and uſeful for the purpoſes to which it is applied: but here you are told that there are various and very material alterations: the defendant therefore has been correcting errors, and not ſervilely copying. If you think ſo, you will find for the defendant; if you think it a mere ſervile imitation, and pirated from the other, you will find for the plaintiff." [Verdict for defendant.] No action therefore lies in future for publiſhing ſea charts on an improved and more uſeful principle, even though many of the lines ſhould be copied from older charts.

In Eaſter term, 10 Geo. III. Wil. 60. Sayer loſt his action againſt Dicey for copying and ſelling a print, becauſe though the *year* of our Lord, wherein the original plate was publiſhed was engraved thereon, the *day of the month* was not.

In Michaelmas term, 33 Geo. III. 5 T. R. 41. an action was brought againſt Symonds and others, for pirating a portrait of the counteſs of Huntingdon. Bowyer was the original proprietor, and had aſſigned his right through Fittler to Thompſon, by whom the action was maintained. On becoming poſſeſſed of the plate, Thompſon had inſerted his own name in the inſcription inſtead of Bowyer's, "preſerving the original date" of 26th day of Auguſt, 1790; but the objection ſtarted on this ground was over-ruled by the court, and the plaintiff obtained a verdict and 10*l.* damages.

ENGRAVING, English, *Origin and Progreſs of.* In England, the *art* of engraving has gradually ariſen from its rude mechanical practice by our Britiſh anceſtors. It may be ſaid to be indigenous to our ſoil. Roman and Saxon improvements have from time to time been engrafted; and more recently, ſhoots from the engraving of Germany, Italy, and France, have alſo been engrafted by the enterprize of individuals, not by the wiſdom or authority of the ſtate, on the original ſtock. It will probably excite the ſurpriſe of poſterity, that *this* art has hitherto been cultivated, (if ſuch might be called cultivation,) in Great Britain in no other way, though Great Britain be the choſen ſeat of modern commerce; and engraving, being in its nature the moſt commercial of thoſe arts which adminiſter to calm and elegant enjoyment, affords the moſt efficient means of diffuſing through the world a juſt and general taſte in the fine arts, and, conſequently, in thoſe numerous branches of manufacture which are derived from, and ſuſtained by, thoſe arts.

That it was rudely practiſed in this iſland from a very early period, may be ſeen by the remains of inſtruments of war, and other antiquities which have been found in the Celtic and Saxon tumuli; theſe, as is obſerved by that intelligent artiſt and antiquary, the late Mr. Strutt, frequently bear marks of the graver, or of ſome tool which cannot have been very diſſimilar; and the numerous coins of Cunobelin muſt ſatisfy every inquirer of the early Britiſh exiſtence of this ſpecies of engraving, an art which was probably introduced from Rome during the reign of that prince.

The art of die-engraving could not have exiſted alone; it implies the exiſtence of other modes of ingenuity; and, with the uſe of money, muſt have ſpread the ameliorating influence of art. But all riſing ingenuity, and even this mode of engraving, appears to have ſunk under the Roman and Daniſh ravages, which ſoon ſucceeded. Excepting theſe coins, thoſe of Carauſius, and a few others of leſs certain date, and the war implements mentioned above, faint indeed are the traces of Britiſh engraving, until the time of Alfred the Great.

"Under the protection of that excellent monarch," ſays Strutt, "the arts begun to manifeſt themſelves in a ſuperior degree. He not only encouraged ſuch artiſts as were in England at the time, but invited others from abroad; and the works of the Anglo-Saxon goldſmiths, who were the principal engravers of that day, were held in the higheſt eſteem upon the continent as well as in their native country. The caſkets which they made for the preſervation of the relics of ſaints, and other pious purpoſes, were ornamented with precious ſtones and engravings in ſo excellent a ſtyle, as to excite the admiration of *all who ſaw* them." Wonder is the concomitant of ignorance. There is, however, yet preſerved in the Muſeum at Oxford a very valuable jewel of gold, adorned with enamelling, and a kind of fillagree work, in the midſt of which is ſeen the half figure of a man, which is ſuppoſed by Hickes and Wooton to repreſent Jeſus Chriſt, and conjectured by Strutt to be rather intended for St. Cuthbert. The back of this curious remnant of antiquity is ornamented with engraved foliage and flowers. From the unqueſtionable teſtimony of its own legend, this jewel is known to have been made at the command of Alfred the Great, and was one of the very few articles he could have carried with him when he retreated to the iſle of Athelney; where it has ſince been found.

Archbiſhop Dunſtan is ſaid to have worked in the precious metals, frequently adorning his works with images and letters which he engraved thereon. Oſbern (his biographer) calls him the firſt of engravers; but it has been emphatically obſerved, that he who could add the title of *Saint* to the name of Dunſtan, would not heſitate to call him a Raphael in painting, or an Audran in engraving; and the ſpecimen of his drawing, which is ſtill preſerved in the Bodleian library, leaves us little to regret in the entire loſs of his engravings.

The engraving of Dunſtan and his contemporary *workmen*, was doubtleſs the degenerate iſſue of the art which the patronage of Alfred had called forth. In the tempeſt of war, and the night of ignorance and ſuperſtition that ſucceeded, ſcarcely a glimmering of its light was ſeen. The mingled work of the engraver, chaſer, enameller, and goldſmith, which is ſeen in Alfred's jewel, entirely diſappeared, but die-engraving, as it afforded the means of iſſuing money, became to the Anglo-Saxon princes an art of neceſſity, becauſe inſeparable from the exiſting ſyſtem of government and polity; and hence, while other arts pined and periſhed, it was enabled to ſurvive the inclemency of thoſe barbarous ages, and to preſerve and tranſmit to better times the art of the engraver.

Laws of Athelſtan and Canute, appointing the number of minters who ſhall reſide in their principal towns, and for the puniſhment of thoſe who ſhall dare to adulterate the coinage of the realm, are ſtill extant, and may be read in Thwaite's obſervations on Anglo-Saxon and Anglo-Daniſh Coins.

It may be preſumed, that the art of die-engraving, and the weak tenures by which landed property was previouſly held, gave riſe to the engraving and the uſe of ſeals. Before their introduction, Ingulphus expreſly ſays, that lands were ſometimes diſpoſed of by word of mouth; ſometimes by laying a turf of the land granted with religious ſolemnity on the holy altar; and in other inſtances the lord gave to the tenant a ſword, bow, helmet, arrow, or drinking-horn to certify the tranſfer; a drinking-horn is mentioned by Lewis as being in the poſſeſſion of a Mr. Pyſſey of Berkſhire, on which was engraven, "I king Knoute (Canute) have given thee this horn to hold thy land by."

In corroboration of the idea that the numiſmatic proceſs ſuggeſted both the manner of engraving and of *uſing* ſeals, we may mention that the matrices of ancient Engliſh ſeals, of which ſome few are yet remaining, are formed with the ſame kind of cutting and punching implements which were uſed by the die-engraver; they were of braſs, as were probably the dies of that period, and from that time to the preſent, metal ſeals have continued to be executed with the ſame implements uſed in the ſame manner, or with no other variations than have been produced by the gradual improvement of ſociety operating on the peculiarities of individual talent: alſo (ſee Seal-engraving,) that they were at firſt impreſſed as money is coined, namely, by a forcible blow, and that *lead* received the impreſſion; and from the teſtimony of Ingulphus it further appears, that ſeals were by no means common in England before his time; he ſays that, "the Normans, diſliking the Engliſh manner of ratifying their chirographs (or charters), ordered them to be confirmed by impreſſions on *wax* from the ſpecial ſeals of the parties concerned. The only ſeal in England that is known to have been impreſſed on wax before this period, is that of Edward the Confeſſor; but as this prince is known to have received his education in Normandy, the ſingularity is accounted for.

From this time the uſe and ſacredneſs of ſeals went on increaſing in the public eſtimation, ſo that before the lapſe of a century, their devices, forms, and ſizes, appropriated to the different ranks in ſociety, were gradually ſettled. Even the etiquette of ſealing on different coloured waxes, was aſcertained with ſufficient ſcrupuloſity.

An impreſſion from the ſeal of Anſelm, the primate, has been copied, and is introduced (ſee *Pl. of Britiſh Engravings*, *fig.* 2.) from which ſome idea may be formed of the Anglo-Norman ſtyle of deſign and engraving, as compared with what had preceded it. The archbiſhop has loſt his head, and has probably been decapitated in effigy, on account of his cropped hair, and by ſome of thoſe reſentful partizans of the long and curled locks, which were faſhionable at the court of William Rufus. Againſt long hair, Anſelm had preached with ſome apparent ſucceſs, and with a vehemence which is highly extolled by Eadmer, his companion and ſecretary; but it has been obſerved, that though the clergy at that time could overturn thrones, and had authority ſufficient to ſend above a million of men on *their* errand, to the deſarts of Aſia, they could not prevail againſt certain faſhions.

It appears that ſome argillaceous ſubſtance, apparently pipe clay, has in this inſtance been mixed with the wax of the ſeal; which has afterwards been painted either with a view to its better preſervation, or to give the true tint of the rank of a Norman archbiſhop. The ſmall folded parchment to which it is appendant, or rather which depends from it (ſee the engraving) is a grant of church land. The prolixity of modern legal forms might bluſh before its brevity.

About, or ſoon after, the time now under our obſervation, a new ſpecies of engraving, more ſimple in its nature than thoſe which had preceded it, was either introduced into or invented in England; of which there is ſcarcely an old country church of any conſequence, but affords ſome curious ſpecimens, and England more than any other nation in Europe. The braſs plates on our old ſepulchral monuments are executed entirely with the graver; the ſhadows, where ſhadowing is attempted, being expreſſed by lines (or ſtrokes,) ſtrengthened in proportion to the required depth of ſhade, and occaſionally croſſed with other lines a ſecond, and in ſome inſtances a third time, preciſely in the ſame manner as a copper plate is engraven that is intended for printing. On other occaſions a mere outline only has been cut.

Theſe engraved effigies are often found cemented on thoſe horizontal tomb-ſtones, which form part of the pavement within the churches, where the feet of the congregation, which kept the lights bright by friction, filled the inciſions with duſt, and thus darkened the ſhades; very neat or exquiſite workmanſhip was not therefore aimed at, and is not to be expected; yet ſome of theſe engravings bear no ſmall evidence of the abilities of thoſe by whom they were performed, and conſidering the dark period during which they were executed, are entitled to more praiſe than many engravings which have been ſubſequently produced. The engraver's ſtyle of drawing the human figure differs little from that of the contemporary illuminators of miſſals, and though the hands, feet, and other nudities are rarely tolerable, the ſtiffneſs of the draperies does in many inſtances bear conſiderable reſemblance to the tiſſued and embroidered veſtments of the entombed abbots, and other dignitaries of the early Catholic church; while the faces occaſionally diſplay attempts not altogether ſucceſsleſs, as it ſhould ſeem, at individual portraiture.

That which has been ſelected as a ſpecimen of this mode of engraving, is from the tomb of William de Fulbourn, in Fulbourn church, Cambridgeſhire, and is copied, with the permiſſion of the Meſſrs. Lyſons, from their Magna Britannia. William de Fulbourn was appointed a baron of the exchequer in the year 1328, and is here repreſented (ſee the *Plate* of *Engliſh Engravings*, *fig.* 3.) "with the effigies of an eccleſiaſtic in a richly ornamented cope, under an elegant canopy, engraved on braſs," &c. &c. See Lyſons's Cambridgeſhire, p. 64. Part of the canopy and finale have been omitted on account of the ſmaller dimenſions of our plate. The pattern of the embroidery, as may be ſeen, is far from being inelegant, and the recurring initials, (W. F.) roſes, and other ornaments, are engraved with no inconſiderable care and neatneſs.

Philoſophers have remarked how frequently man has ſtumbled or ſtopt ſhort at the very threſhold of improvement. From the time of the Cruſades, Great Britain has been in poſſeſſion of an art of engraving from which ink might have been delivered, and conſequently impreſſions multiplied, either on the ſame vellum on which books were formerly written, or, ſince the middle of the 12th century, on paper itſelf: yet until about the year 1460, no man appears to have thought of delivering ink from the inciſions of the graver.

Whether accident or deſign, and whether Italy or Germany had the honour of giving birth to an invention, of which three centuries and a half have not ſerved fully to develope the important conſequences to ſociety, has been much diſputed among the curious. Mr. Strutt is among the number of thoſe who have purſued theſe inquiries with conſiderable diligence. After diſcuſſing the German and Italian pretenſions, he at length brings forward an impreſſion from an engraved braſs plate in his own poſſeſſion, which he conceives to be Engliſh, and which he thinks *may* claim the palm of early date. Its ſtyle of art is truly that of the early German ſchool, and alſo that of the engravers of the Engliſh ſepulchral braſſes of the fifteenth century; yet from another circumſtance, which ſhall be mentioned anon, the writer of this article is led to think that Mr.

Strutt's plate, and the tenor of his reaſoning thereupon, are more curious, than his concluſion is well founded.

Mr. Strutt ſays, "no one ſeems to have ſuppoſed that we could lay even the moſt diſtant claim to a rivalſhip (much leſs to a priority) with reſpect to the early practice of engraving, with any of the continental nations famous for the arts. But when we conſider how many engravers we had in England, about the time in which the diſcovery of taking impreſſions from copper-plates was made, as the many monumental engravings remaining in our churches to this day ſufficiently teſtify, (and a little examination of theſe early ſpecimens of the art will prove how well they were adapted to the purpoſe of printing,) we ſhall readily conceive that if they did not themſelves diſcover this mode of multiplying their works, they would at leaſt have inſtantly adopted it, as ſoon as the knowledge of ſuch an invention had reached them."

"There can be little doubt of the antiquity of the engraving here produced; and that it was made for the purpoſe of printing, the letters being reverſed upon the plate ſufficiently prove. So that if it ſhould be urged, though we ſee no kind of reaſon for ſuch a ſuppoſition, (this is ſurely more than ſtrict criticiſm will concede to Mr. Strutt,) that the plate itſelf was executed abroad, at the command of ſome Engliſh devotee, it muſt at leaſt be granted that the mode of taking impreſſions from it was underſtood in England, or the plate could not have been of any uſe to the owner of it; and that the engraving was the work of ſome Engliſh artiſt, *or* executed at the deſign of ſome Engliſh perſonage; no one, I conceive, will doubt on examining the contents of the inſcriptions. They conſiſt of particular invocations to ſaints, comprehended in ſeven compartments, the initial letters of each invocation or prayer being ornamented with the repreſentation of the perſonages to whom it is addreſſed." Here follows a particular deſcription of the ſeveral compartments.

"The addreſs to the Engliſh ſaints in the fifth petition, plainly, we think, determines the country to which it belonged. The ſtyle of the drawing, and the manner in which the little figures are compoſed, being placed in the initial letters, bear an exact reſemblance to the illuminated delineations which we meet with in manuſcripts of the fifteenth century, eſpecially towards the commencement of it; and the writing alſo has every appearance of equal antiquity."

If we ſhould proceed thus far with Mr. Strutt, and admit his reaſoning, it will ſcarcely be practicable to travel with him further, though he be in general, as to matters of fact, an excellent guide. The invocations, which cover the far greater part of the plate, are not in the Engliſh, but the Latin language, and Mr. Strutt informs his readers, that they are "evidently ſtamped upon the plate with ſmall punches, and re-touched afterwards with the graver." Now, no man would cut an alphabet of punches, (or puncheons, as they are ſometimes technically termed,) for the ſake of engraving, or ſtamping, ſuch a plate as Mr. Strutt has brought forward, nor would probably any cauſe of leſs magnitude than the formation of matrices for an alphabet of moveable types, induce an artificer to beſtow the time and pains, neceſſary to the production of ſuch an alphabet of puncheons. From this ſingle circumſtance, the preſent writer is inclined to refer the engraving in queſtion, in whatever country it may have been executed, to a period ſubſequent to the invention of moveable types; conſequently if it was executed in England, it muſt have been after the year 1471, when, according to Dr. Middleton, Caxton had returned from abroad, and began to print books in Weſtminſter Abbey.

Another reaſon, which does not ſeem to have preſented itſelf to Mr. Strutt, why the invention of printing with the rolling preſs from plates of metal cannot, in fairneſs, be aſſigned to England, is that to ſuppoſe this art to have been known here before the experiments of Finiguerra, we muſt alſo ſuppoſe that almoſt a century elapſed between the firſt and ſecond examples of Engliſh copper-plate printing, which is a thing not to be ſuppoſed for a moment.

Of the engravings that accompanied an edition of Veſalius's anatomy, which was printed in England in the year 1545, Mr. Ames ſays, "theſe plates are ſome of the firſt rolling preſs printing in England." Of theſe plates, Thomas Geminus, or Gemini, was the engraver: they were not the very firſt that were *publiſhed* here. "The birth of Mankind, otherwyſe called the Woman's book," made its appearance in 1540, and contains ſome ſmall anonymous copper-plate cuts, yet Geminus might poſſibly have begun his engravings more than four years before the date of their publication: at leaſt he is the firſt engraver in England of whoſe name we are in poſſeſſion, and whoſe works were printed on paper.

The firſt edition of Geminus's Veſalius was dedicated to king Henry VIII. He publiſhed a tranſlation by Nicholas Udal, of the ſame work, in 1552, and dedicated it to Edward VI. The tranſlator in his preface ſays, "Accepte therefore jentell reader, this treatiſe of anatomie, thankfully interpreting the labours of Thomas Gemini, the workman. He that with his great charge, watch and travayle, hath ſet out theſe figures in pourtrature, will moſt willingly be amended, or better perfected of his own workmanſhip, if admoniſhed."

Thoſe who have ſeen the maſterly wood engravings to the original Veſalius, publiſhed at Padua, in 1542, engravings that were done under the eye, and, as ſome have ſaid, touched by the hand, of Titian, will perceive that Gemini has left abundant room for admonition: yet the conſideration that his work was a firſt attempt, at once to tranſplant a new art to England, and to extend the knowledge of anatomy, will probably be received as no unſatisfactory apology for the defects of theſe engravings.

Gemini lived in Black-Friars: he printed and publiſhed other books, among which are a ſmall tract on midwifery, with copper-plate engravings, (which is, perhaps, the ſame that is mentioned above, under the title of "the Birth of Mankind, &c.") a prognoſtication relating to the weather, the phenomena of the heavens, &c. decorated with a number of cuts, and another edition of his Veſalius, printed in 1559, and dedicated to queen Elizabeth

Lord Orford has obſerved that, "ſo congenial an art as engraving, when once diſcovered, could not fail to ſpread in an age of literature. That accompliſhed prelate, archbiſhop Parker, who thought that whatever tended to enlighten and cultivate the human mind, was within his province, ſeems to have been the moſt conſpicuous patron of the art, in the reign of Elizabeth. He employed, in his palace at Lambeth, a painter and two or three engravers. Of theſe engravers, the chief was Remigius Hogenbergh, who twice engraved the archbiſhop's head, which, if Vertue be right, was the firſt portrait printed in England, from an engraving on copper; Remigius had a brother whoſe name was Francis, by whoſe hand is extant a print of queen Mary I. dated in the year 1555. Under it is written "Veritas Temporis Filia." In the ſet of Saxton's maps, thoſe of Gaul and Belgium are by this artiſt, and he has alſo engraved *views* both in Bruin's Civitates Orbis Terrarum, printed in 1572 at Cologn, and in Abraham Ortelius's Theatrum Orbis Terrarum, printed in 1570 at Antwerp. On the foreground of one of the views contained in the latter work, are two figures dreſſed in the coſtume of the times, one of which is the portrait of Ortelius himſelf, (as the inſcription beneath informs us); and the other that of Hoefnagle the engraver, who, though a native of Antwerp, was among the firſt of thoſe who practiſed the art in England. The map of England in this work was by Humphrey Lhuyd of Denbighſhire, and that of Spain by Thomas Geminus, whom we have already mentioned. Lord Orford thinks it creditable to England, that we had at this time, "profeſſors worthy of being employed to adorn Flemiſh editions; Flanders being at that time a capital theatre of arts and learning;" and Ortelius himſelf commends the Engliſh engravers, ſpecifying beſides thoſe whom we named, Antony Jenkenſon, and Robert Leeth.

Chriſtopher Saxton deſerves mention here, for at once extending the knowledge of our national geography, enlarging the field of engraving, and raiſing himſelf to eminence from the condition of a ſervant. He was a native of Yorkſhire, and lived at Tingley, near Leeds, in the ſervice of Thomas Sekeford, eſq. maſter of the Requeſts, and of the court of Wards. Encouraged by this gentleman, who kindly aſſiſted him with money, Saxton undertook to make a complete ſet of maps of the counties of England and Wales. Many of the plates he engraved himſelf, and in others was aſſiſted by Francis Hogenbergh, Nicholas Reynold, and Auguſtin Ryther. Six years were employed in the work, which commenced in the year 1573. Theſe were *the firſt* county maps that ever appeared in England, and Thoreſby ſays of that of Yorkſhire, which is three feet wide, that it is "the beſt that ever was made of that county." Ryther had the chief hand in engraving it, and at the corners are views of the city of York, and the port of Hull. Theſe maps are alſo adorned with the royal arms, and thoſe of the patron "Maſter Sekeford," and are dedicated to the queen.

In lord Orford's catalogue is a worthleſs portrait of George Hoefnagle, who engraved about this time a map of Briſtol, and a view of the palace of Nonſuch, which, though once ſo magnificent, is now only known from deſcription and the print of Hoefnagle. He worked entirely with the graver, and, as has already been mentioned, was one of thoſe employed by Ortelius, in his great work, which may truly be called ſo, when we conſider the time when, and the circumſtances under which, it was produced.

We have paſſed over Cole, Bettes, the de Brees, and others: and even the names of many of thoſe who ſerved to mark no era in the art of which we are here tracing the progreſs in England; who neither invented nor introduced a new ſtyle, nor diſtinguiſhed themſelves in thoſe which were previouſly known and practiſed; we ſhall paſs over them with a general reference to Strutt, Grainger, and lord Orford's catalogue, where their names and the dates of their works may be found, with ſuch liſts of their performances as thoſe authors, with the aſſiſtance of George Vertue, were able to form or collect.

Notwithſtanding the praiſe of Ortelius, Engliſh copperplate engraving retained, for more than an hundred years, much of its original coarſeneſs and vulgarity. The ſtyle of Reginald Elſtracke, who lived at the cloſe of the ſixteenth and beginning of the ſeventeeth centuries, is occaſionally ſomewhat neater than that of his predeceſſors, but ſtill deſtitute of taſte. His inſtrument was the graver, but faint indeed are the mental rays that attended its progreſs.

Elſtracke worked chiefly for the bookſellers; and his beſt works are portraits, which are for the moſt part, if not entirely, after his own drawings. They are in number at leaſt thirty; and among the beſt of them are thoſe of ſir Philip Sydney, engraved ſoon after his death, and "ΒΑΖΙΛΙΩLOGIA, or the true and lively Effigies of all our Engliſh Kings from the Conqueſt to the preſent time" (1618.) His portrait of queen Mary of Scotland is probably, on the whole, his beſt performance.

Francis Delaram was contemporary with Elſtracke. His workmanſhip, for it can ſcarcely yet be called art, and certainly not fine art, was ſomewhat neater than that of Elſtracke, but equally taſteleſs. The ſquareneſs or rectangularity of his croſſings gives a peculiar dryneſs to his ſtyle of engraving; he drew but indifferently, his outlines are hard, and his draperies heavy. Unleſs we may except the following plates, which are after his own deſigns, his portraits are the beſt of his works. The frontiſpiece for "Wyther's Preparation to the Pſalter," ornamented with emblematical figures, and dated 1619. The frontiſpiece to "The Seven golden Candleſticks," 1624. "Nero Cæſar, or Monarchie Depraved," 1627; this alſo is a frontiſpiece. And the beſt of his portraits are thoſe of "James the Firſt," an upright whole ſheet print, as large as life. "Queen Mary and Queen Elizabeth," ſmall uprights. "Henry Percy, Earl of Northumberland," dated 1619. "Frances, Ducheſs of Richmond and Lenox," and "Sir Thomas Greſham."

But the family of the Paſſes, or *de* Paſſes, of whom the elder came hither from Utrecht, early in the ſeventeenth century, introduced a better taſte, and a neater and more elaborate ſtyle of engraving than had hitherto been practiſed in England.

Criſpin de Paſſe was a man of letters, ſtudious, and of a liberal mind. Holland's Heroologia was embelliſhed and publiſhed at his expence; and in the preface to a drawing-book, publiſhed by him at Amſterdam, in the year 1643, (after his departure from England,) he diſcovers ſome knowledge in geometry and perſpective; gives directions for the proportions of the human body; for drawing in the academy by lamp light, and for the uſe of the lay-figure in ſtudying draperies; and details the proportions of horſes, lions, and other quadrupeds, and of birds and fiſhes. In the ſame preface he ſays of himſelf that he applied early to the ſtudy of the arts, and mentions Rubens, Bloemart, and other diſtinguiſhed contemporary artiſts, as his friends and encouragers: but he appears alſo to have looked with advantage at the neater productions of the German ſchool of engraving. The following is a tolerably juſt eſtimate of his powers as an artiſt, and is from the pen of the late Mr. Strutt.

"Paſſe worked entirely with the graver, in a neat, clear ſtyle, which has much originality; and, excepting ſome little ſtiffneſs which frequently appears, and the want of harmony with reſpect to the diſtribution of the light and ſhadow, (a fault which prevailed at the time in which he lived,) his beſt works poſſeſs a very conſiderable ſhare of merit, eſpecially his portraits, many of which he drew from the life; and the far greater part of his hiſtorical and emblematical ſubjects are engraved from his own compoſitions. He drew the human figure very correctly," (but the proportions and ſtyle of his figures are thoſe of the ſchool of Rubens,) "and marked the extremities with a degree of exactneſs, not uſually found in the works of thoſe maſters who employed themſelves upon ſmall ſubjects."

Mr. Strutt ſhould have recollected here, that exquiſite examples of delicate marking and elaborate workmanſhip might then have been ſeen, and, probably, were ſeen by Criſpin Paſſe, in the works of the Behams, Penz, and thoſe other German artiſts who are emphatically termed the *little* maſters; particularly in the engravings of Bartholomew Beham, who had ſtudied under Marc Antonio.

The ſons of this artiſt, who were Criſpin junior, William, and Simon, and his daughter Magdalen de Paſſe, followed the inſtructions and the ſtyle, and in ſome inſtances ſurpaſſed the merits, of their father; though the works of Magdalen, the firſt female engraver we read of who practiſed the art in England, are not equal to the beſt of thoſe of her brethren. In three plates from Ovid's Metamorphoſes, which ſhe has engraved after pictures by Elſheimer, ſhe has judiciouſly imitated the ſtyle of count Goudt, but has not produced the ſame forcible effect, nor attained the ſame exquiſite degree of finiſh. Liſts of the numerous portraits and other engravings by this family, may be ſeen in lord Orford's Catalogue, and Mr. Strutt's Dictionary of Engravers; and in the Royal library at Paris, before the revolution, was a collection of their works in large volumes, of which there were either two or three.

From Simon Paſſe the art deſcended to his pupil John Payne. Other engravers were practiſing in England at the time, but of inferior merit. Payne had caught the mantle of the Paſſes. Strutt ſays of him that "he was a man of genius, and though his works are not very numerous, they nevertheleſs manifeſt his ſuperior abilities. He was recommended to Charles I., and had a fair proſpect of making his fortune; but careleſs of that as he was of his fame, he neglected his buſineſs and died in indigence, A.D. 1647 or 48, before he had reached his 40th year. His chief engravings conſiſt of frontiſpieces and other book-plates, and portraits. But he alſo engraved a variety of other ſubjects, ſuch as landſcapes, flowers, &c. His portraits, however, are, in my opinion, by far his beſt works. Thoſe he executed entirely with the graver in a free open ſtyle, ſo managed as to produce a very pleaſing effect. Mr. Evelyn, ſpeaking of this artiſt, commends him alſo for a ſhip which he engraved. This ſhip, as Vertue informs us, was the Royal Sovereign, built by Phineas Pett. The print was of a prodigious ſize, and engraved on two plates, being, when joined, three feet long, by two feet two inches high." His beſt portraits are from Cornelius Janſen.

Having proceeded thus far with the progreſs in England of the art of engraving on *copper*, it behoves us to attend to the introduction and early progreſs of that of engraving on *wood*.

The art of engraving, and printing from, blocks of wood, was introduced into England about the ſame time with the mode of printing with the rolling preſs from engravings on copper: if, indeed, *wood* were really the material uſed for thoſe engravings which are called, and generally ſuppoſed to be, wood engravings, and which are common from the time of the firſt promulgation of the art through the fifteenth and the two following centuries, and where the printing ink is evidently delivered from "lines croſſing each other," and with the letter-preſs.

The earlieſt Engliſh engravings of this kind which the preſent writer has examined, unleſs thoſe which are publiſhed with the mark of Holbein are really by his hand, and were any of them performed after his arrival in this country, are thoſe of Chriſtopher Switzer, who lived at the cloſe of the ſixteenth and beginning of the ſeventeenth centuries. He was probably a German by birth, though he reſided in England. Vertue ſays, he cut a ſet of the broad ſeals of England, which may be ſeen in the Harleian library, but impreſſions from the blocks of coins and ſeals which he cut for Speed's hiſtory are not uncommon; and here the remarkable dark croſſings occur, and may be particularly obſerved in the four blocks which are entitled "portraitures of the ancient and of the more civil Britons." Speed calls this artiſt "the moſt exquiſite and curious hand of that age," and he probably was ſo, if we confine the remark to wood-engraving, and to England. Evelyn ſays of Switzer's ſon, who ſucceeded him in his profeſſion, and was alſo named Chriſtopher, "we have likewiſe a Switzer for cutting in wood, the ſon of a father, who diſcovered his dexterity in the herbals ſet forth by Mr. Parkinſon, Lobel, and divers other works with due commendation;" which ſhews that the elder Switzer engraved the blocks of botanical ſubjects for Lobel's obſervations, and Parkinſon's "Paradiſus Terreſtris," which was publiſhed in 1629.

It may have been perceived that of the fact of dark lines croſſing each other, being printed from the ſurfaces of engraved blocks and with the letter-preſs, the preſent writer entertains conſiderable doubt. His doubt is founded on the extreme difficulty, amounting to impracticability, though not to abſolute impoſſibility, of cutting away the minute lozenges of wood, or interſtices between the croſſed lines, ſo as to leave ſuch a ſurface of dark croſſings as muſt have preſented itſelf to the letter preſs printers of this period.

To print dark croſſings from the inciſions of the graver, and with the rolling-preſs, may be conceived to be comparatively eaſy: but as printing from the *ſurface*, and with the letter preſs, was preferred on account of its ſuperior facility, we are reduced in reaſoning upon theſe engravings, if we ſuppoſe them to have been performed on *wood*, to the monſtrous abſurdity of ſuppoſing, that a difficult and tedious, was preferred to a ſimple and eaſy proceſs, and that on account of its ſuperior facility!

Theſe conſiderations have led to the ſuppoſition that the prints in queſtion were not taken immediately from the engravings, but from caſts of ſome kind, for which the engravings, on whatever ſubſtances they were performed, did but ſerve as matrices or moulds. Yet wood cannot be caſt in moulds: and in the library of Mr. Anthony Carliſle, profeſſor of anatomy to the Royal Academy (whoſe name is, undeſignedly on the part of the author, omitted in a note to the volume of lectures on engraving delivered at the Royal Inſtitution, p. 205.) are two books illuſtrated with letter preſs engravings, which appear to contradict the above hypotheſis. It may not be impertinent here to tranſcribe a paſſage from the *manuſcript* of the lecturer.

"I have to regret that this part of the lecture is ſo little better than a ſtatement of doubts. Since this volume has been in the preſs, I have ſeen, in the library of Mr. Carliſle the anatomiſt, a copy of Johnſon's tranſlation of Ambroſe Parey's anatomy, printed in 1691, which is illuſtrated with letter preſs engravings where dark croſſings frequently occur, and in the preface to which the author ſays, 'the figures in this work are not the ſame uſed by my author; but according to thoſe of Bauhine, which were uſed in the work of Dr. Crook.' Upon referring to the latter work, which I found in the ſame library, and which was printed in 1631, it was evident that the prints were not copies, but impreſſed from the very ſame engravings: but there was this remarkable difference which *ordinary* incredulity could ſcarcely ſtand againſt, that in Johnſon's work the prints were obviouſly impreſſed from ſome ſubſtance which had been *worm-eaten* in the courſe of the ſixty years it had lain by, and which could not therefore have been *metal*." The remainder of this note would be ſuperfluous: the inference is obvious. But, the public muſt not be led aſtray, nor muſt the author of that note let paſs this opportunity of controverting himſelf.

It has ſince come to his knowledge, and is an undoubted fact, that old lead is not unfrequently found perforated by worms, or by ſome ſmall animalculæ, which leave behind circular holes of exactly the ſame kind and ſize, which we ſo frequently ſee in old wooden furniture, books, &c. He reſumes therefore his opinion, and indeed a further and more particular inſpection of the productions of this kind, of the German ſchool, has confirmed his belief, that the numerous prints produced at this early period in Germany and the Low Countries, which are ſuppoſed to be impreſſed from engravings on wood, are really printed from metal caſts.

As Dr. Crook's anatomical work was publiſhed but two years after Parkinſon's Paradiſus Terreſtris, it is probable that one of the Switzers engraved the anonymous anatomical figures which are the ſubjects of the above comments. The art of engraving, on whatever ſubſtance was then employed to enable the printer to produce dark croſſings from the ſurface of the work, was an exotic tranſplanted from Germany or the Low Countries, and appears never to have taken root in our ſoil. It died away with or ſoon after the Switzers, and has never revived ſince: for the art of engraving on wood, as practiſed by the Bewicks of Newcaſtle and their diſciples, and imitators, is to be conſidered as quite a diſtinct art. But, for further information on this ſubject, ſee Letter Press Engraving, and Wood Engraving.

Contemporary with the younger Switzer and with Hollar, of whom we ſhall preſently treat, were Robert VanderVoerſt and Lucas Vorſterman, who were rival competitors for public fame, and rivals alſo in the favour of king Charles I. Charles was the firſt Engliſh monarch who was ſufficiently ſenſible of the beauty of engraving, and of the popular and important purpoſes to which it might be applied, to appoint an engraver royal. The king took care to ſee that the title was not worthleſsly thrown away, in mere kindneſs to a courtier, and Voerſt was the firſt artiſt on whom that honour was conferred. He was a native of Holland, and in what year he came hither is uncertain. He was an able draftſman, and hatched his drawings with pen and ink, as was the general cuſtom of the artiſts, particularly the engravers, of that period. A drawing of this kind performed on vellum, and of which the ſubject was the Madonna with the infant Jeſus and St. John, he had the honour of preſenting to the king, for whom he afterwards engraved a portrait of his majeſty's ſiſter, and a plate from a picture which Vandyke painted to ſupply the place of that one of Titian's Cæſars which by ſome accident had been loſt or deſtroyed: ſo that Voerſt's title was not merely nominal. He engraved alſo from Vandyke, the portraits of Charles I. and his queen; (from the ſame celebrated picture which has been ſubſequently engraved by Vertue) that of the queen alone; ſir Kenelm Digby, Inigo Jones, and ſeveral others, of which a liſt may be ſeen in lord Orford's catalogue. He handled his graver in a bold, free, and commanding ſtyle.

The ſtyle of Vorſterman exhibits more careful finiſhing and painter-like feeling, and muſt on the whole be allowed to be ſuperior to that of his rival. He was to Rubens and Vandyke in England, and the Low Countries, what Marc Antonio was to Raphael in Italy. He may be ſaid at once to have ſucceſsfully tranſlated and ſtereotyped the great originals of thoſe very diſtinguiſhed painters.

Mr. Strutt ſays of him with great truth that no one ever engraved more ſucceſsfully from the pictures of Rubens: than whom, no painter that ever lived had the pleaſure of ſeeing ſo great a number of his pictures finely engraved. Vorſterman drew the human figure with correctneſs and taſte. He was maſter of the graver, and could handle it with the utmoſt facility; but he paid much greater attention to the general effect of his prints, than to the regularity of the ſtrokes; and like Gerard Audran, wiſhed to enter into the thoughts of the maſter, and tranſcribe on copper the very life and ſpirit of his pictures, rather than ſhew his own dexterity in the mere mechanical part of the workmanſhip. The heads of his figures are finely drawn, and the extremities marked in a very maſterly manner. Vertue mentions with approbation two drawings by Vorſterman, namely, a portrait of prince Henry, and a woman's head, after Leonardo da Vinci.

This celebrated engraver was a native of Antwerp, but from whom, or whether from any maſter, he learned the principles of painting and engraving, does not appear. He came over into England about the year 1623, and was occaſionally employed both by king Charles I. and the earl of Arundel. His engravings are numerous, and chiefly from Rubens, Vandyke, and Holbein. Among thoſe which may be mentioned with diſtinction are; from the former maſter, "The fall of the Damned," (a large upright); "The battle of the Amazons," a large and grand plate, printed on ſix ſheets; "Lot leaving Sodom;" "The temptation of Job;" "Suſanna and the Elders," and ſeveral others, particularly the "Return from Egypt," which he has treated in a manner differing from his uſual ſtyle, and more bold and open. From Vandyke he has engraved a dead Chriſt, ſupported on the lap of the Virgin, and a conſiderable number of admirable portraits, among which are thoſe of Charles I. and Vandyke himſelf; and from Holbein, he has engraved "Thomas duke of Norfolk," with the ſtaves of lord treaſurer, and earl Marſhal, "Eraſmus, ſir Thomas More," and the painter himſelf. Sir Thomas has here a flatter face and ſmaller bonnet than in other pictures of him; and from the circumſtance of Holbein's pencil being placed in his left hand, may be inferred, not that this print was a copy from another without being reverſed on the copper (as lord Orford has ſurmiſed) but that Holbein painted with his left hand: a truth which the painter here meant to ſay of himſelf, and which the engraver has faithfully reported.

Nor muſt the illuſtrious name of ſir Anthony Vandyke be omitted, in enumerating thoſe of the artiſts who contributed to accelerate the progreſs of Britiſh engraving. The portraits which he etched of Snyders, Vorſterman, Paul Pontius, and other diſtinguiſhed artiſts who were his contemporaries and friends, excited the juſt ſurpriſe and emulation of the painters and engravers of that age, and the beſt of them have continued to the preſent to be examples of excellence. Among the beſt may be reckoned that head of himſelf, looking over his ſhoulder, where he has introduced the golden chain which he had the honour of receiving, together with his majeſty's picture in miniature, at the hands of Charles I. a circumſtance which ſerves to ſhew that he etched this plate at leaſt, and preſumptively others, after his arrival in England. In ſome of thoſe which he had previouſly executed, we ſee him contending, as it were, againſt the difficulties of his own imperfect knowledge of the newly acquired art, and that his plates are accordingly blurred with accidental ſcratches, and blotted and ſtained with foul biting, which all the ſkill of Bolſwert, Neeffs, and Vorſterman, who ſeverally employed the graver in finiſhing moſt of his draperies and ſome of his faces, has not been ſufficient to obliterate or conceal. His ſtyle of etching is original, vigorous, free, and expreſſive, and in ſome inſtances he has finiſhed his heads with conſiderable care. The tranſcendental taſte and judgment which he has ſo amply diſplayed in his pictures, guided and determined his hand in etching, and though nearly two centuries, which have boaſted of their refinements, have elapſed ſince the period of their production, his "Ecce Homo" and his portraits, ſtill preſerve their ſtations in the collections of the taſteful, and are ſtill eſteemed among the moſt highly valued ſtudies both of the portrait painter and engraver. By liberating Britiſh portrait engraving from the ſtiff regularity of the graving tool, which had before been too much regarded as a teſt of merit, Vandyke extended the views of the taſteful, while he taught the true value of outline, and light and ſhade.

It would not now be eaſy to aſcertain the preciſe time when that important branch of engraving, which is technically termed *etching*, (for an explanation of its proceſs, ſee the article ETCHING,) was introduced into England. Ortelius's and Bruin's publications contain ſome prints where etching appears to be mingled with the work of the graver, but if they are by Engliſh artiſts, thoſe artiſts probably acquired their knowledge of etching in Flanders, where they practiſed it; and on the whole it ſeems highly probable, that no etching was performed in England till the period of Vandyke's and Hollar's reſidence in London, and that the honour of having introduced it belongs to one or the other of theſe diſtinguiſhed characters. Vandyke was here and in high favour at the court of Charles I. when Hollar arrived, but whether he had then performed any of his admirable etchings is no where recorded; and as they are without dates, cannot now be eaſily aſcertained. As neither of theſe diſtinguiſhed men was the diſcoverer of an art, though each was the inventor of a ſtyle, it may be enough to believe it highly probable, that Vandyke was the firſt perſon who etched portraits in England, and Hollar the firſt who etched landſcape and natural hiſtory.

It is not certain, that William James Delft, or *Van* Delft, (for he was ſo named from the place of his nativity,) was ever in England. Yet from his ſtyling himſelf the king of England's engraver, and engraving portraits of Charles I., his queen Henriette Maria, and the duke of Buckingham, it ſhould ſeem to be not improbable that he ſucceeded Voerſt. Strutt ſays of him, that "he drew and painted portraits with great taſte, and in a ſtyle that acquired him conſiderable reputation; but as an engraver of portraits he is more generally known, and in that light only I ſhall conſider him. He worked entirely with the graver, and handled that inſtrument with the greateſt facility. He drew correctly, and his beſt prints are very finely finiſhed. Conſidering the great number of plates which were completed by the graver of this artiſt, it is not reaſonable to ſuppoſe they ſhould be all alike or equal in merit. Accordingly I ſhall diſtinguiſh two manners in which he engraved, and produced many excellent plates in both: firſt, a bold, powerful open ſtyle, productive of a fine effect; and as a ſpecimen of it I would refer the reader to the portrait of Hugo Grotius, dated 1632: ſecondly, a neat and much more finiſhed manner, as we find in the admirable portrait of Michael Miravelt (a near relation to the engraver,) from a picture of Vandyke." From the pictures of Michael and John Miravelt, he engraved a conſiderable number of portraits.

Wenceſlaus Hollar, who has been already named, if not the firſt perſon who practiſed the art of etching in England, was the firſt who particularly diſtinguiſhed himſelf in etching landſcape, ſhipping, antiquities, and natural hiſtory.

This diſtinguiſhed artiſt, a gentleman by birth, was a native of Prague in Bohemia, and intended by his parents to have been educated to the ſtudy of the law; but the civil commotions which happened in his youth, and which led to the memorable battle of Prague, obliging them to abandon this intention, and his genius for art diſcovering itſelf about the ſame time, he was placed under Marian, an able deſigner and engraver of views, and by the time he had attained the age of nineteen, Hollar produced two plates, of which the ſubjects were an Ecce Homo and a Madonna, and child, (the latter from Albert Durer,) which drew forth the notice of the public, and confirmed the hopes of his friends. In the courſe of the next year (1636,) he engraved another of Albert Durer's Madonnas, and a plate which the ſuperſtitious might regard as ominous of his future fate, of "Fortune ſurmounting a Globe," which was alſo from Albert Durer.

He ſoon afterwards excelled in drawing geometrical and perſpective views and plans of buildings; ancient and modern churches and abbies, cities and towns; landſcapes; and various kinds of natural and artificial curioſities, ſome of which he executed with a pen in a very maſterly and peculiar ſtyle. To this art of drawing with a pen, he ſubſequently added the uſe of water-colours, which he occaſionally, in the treatment of ſuch ſubjects, as butterflies, beetles, &c. heightened and enriched with gilding in a very beautiful manner, as the volume of his drawings now in the poſſeſſion of John Townley, eſq. F. R. S. and F. A. S. of Park ſtreet, Weſtminſter, abundantly teſtifies.

After paſſing ſome years in travelling through Germany, during which he drew and engraved views of Frankfort, Wurtſburg, Cologn, and other of its principal cities; but where he met with little encouragement: the earl of Arundel, then on an embaſſy to the Imperial court, met with him at Cologn, and being ſtruck with his uncommon abilities, and particularly delighted with a large drawing of Prague, which Vertue ſays, "was curiouſly and exactly done with the pen and pencil," took him under his protection, and Hollar travelled in the ambaſſador's ſuite, from Cologn to Mentz, Prague, Nuremberg, Augſburg, Wurtſburg, Frankfort, Regenſburg, Vienna, and finally to England, where it is ſaid the noble earl recommended him to the favour of king Charles I.

There is ſome reaſon to fear that lord Arundel's patronage of Hollar was more nominal than real; and that the vanity of the patron was more gratified, than the fortune of the artiſt was promoted, by their connection. That Hollar was left deſtitute by the death of this nobleman, notwithſtanding that political, were then added to his profeſſional, merits, (for he was a zealous adherent to the cauſe of royalty and lord Arundel,) is freely excuſed on the ground of his lordſhip's own reverſe of fortune, but it appears to imply more neglect than the liberal would elſe be diſpoſed to impute to this nobleman, that during the firſt year of Hollar's arrival in England he was under the neceſſity of drawing and etching his view of Greenwich, which is more than two feet in length, for the paltry ſum of thirty ſhillings! Yet the reader muſt wiſh in vain for a more honourable contraſt between the parſimony of Stent, who purchaſed a *commodity* of Greenwich, with no other view than to enrich himſelf by the profits it might produce; and the liberality of the exalted peer, who deſerved his exaltation as the patron and protector of talent, alive to the charms of art, and kindling with the flame of contemporary genius.

But it muſt be candidly allowed that the art of Hollar had little affinity with that of Vandyke, and, ſo dependent is the judgment in fine art of ſome men, upon the opinions of others, that the merit which lord Arundel thought he had diſcovered at Cologne or at Prague, might have faded in his own eſtimation when he approached the light of the court of London. Notwithſtanding his own partiality and native feeling for the merits of Hollar, Vertue is obliged to confeſs of him that "it is certain he could not ſo well enter into that maſter's (Vandyke's) true manner of drawing in his grace and touches, as other engravers, ſome in England and others abroad, who had ſtudied his way or manner of drawing and painting; for which reaſon "he could not obtain Vandyke's recommendation, nor that of his admirers." Portrait painting was then the reigning faſhion in England, and as the national taſte for art was baſking in the meridian ſplendour of the powers of Vandyke, it is not ſurpriſing that the leſs fortunate and more humble claims of Hollar were little ſeen, and met with ſmall comparative encouragement.

Though the warmth of lord Arundel's patronage might perhaps be damped by theſe cauſes, he continued in ſome degree to befriend our artiſt. On his arrival in London, Hollar ſat down with his habitual induſtry to engraving, and after producing his large plate of Greenwich, which ſhewed what he could do in this department of engraving, put aſide for a time his talents for landſcape and natural hiſtory, in order to accommodate himſelf to the public occaſions and the prevailing taſte, and ſoon completed an equeſtrian portrait of his patron, with two plates of king Richard II. kneeling before his patron ſaints, from an ancient altar folding table, and ſome other works from the Arundelian collection, including the curious cup which was deſigned by Andrea Mantegna.

In the year 1641, which was the year of Vandyke's deceaſe, he engraved ſome portraits, including thoſe of the king and queen, from the pictures of that celebrated painter. He had now been introduced to teach drawing to ſome branch of the royal family. Vertue thinks it was to teach prince Charles, having "ſeen a book mounting the arms or badge of the prince of Wales, (the crown and feathers,) wherein were drawings of parts of faces, &c. to begin to learn from, with ſome of Hollar's hand-writing:" but in an inſcription under his portrait, publiſhed at Antwerp in 1648, and which inſcription is ſuppoſed to have been ſupplied by himſelf, he ſays, he "had been domeſtic ſervant to the duke of York."

However this may have been, the civil wars which broke out ſoon after this maſterſhip or ſervitude, toſſed Hollar about with the royal party, ruined his better hopes, and obliged lord Arundel to return into Flanders. The engraver being left behind, reſolved to try the fortune of war, and entering the army under the command of the marquis of Wincheſter, was made priſoner at Baſing-houſe, in Hampſhire, from which having, with ſome difficulty, effected his eſcape, he went over to Antwerp, in the year 1645, and once more ſought the patronage or conſolation of the earl of Arundel. He remained in that city for ſome years, endeavouring, through means of his art, to retrieve his ſhattered circumſtances; but his patron going to Italy for the benefit of his health, and dying at Padua in 1646, Hollar was left to the accidents of precarious encouragement and the avarice of trade. He fell again into diſtreſs, and was obliged to work for the book and printſellers at very low prices.

Under ſuch circumſtances were produced his book of heads, after da Vinci; his thirty-eight plates of ſhells, with many other ſubjects from the Arundelian collection; a conſiderable number of landſcapes after Breughel, Elſheimer, Teniers, and other maſters, and a ſtill greater number of portraits, among which were thoſe of Charles I., Charles II. when a youth, after Vandyke, the duke of York, after Teniers, which is now become very ſcarce, and his own portrait, after Meyſens. At the period of the reſtoration Hollar returned to England, where, though he found ſufficient employment to occupy his time, the prices he received for his engravings were ſo very inadequate to the labour which they neceſſarily required, that he could but barely ſubſiſt; and the plague putting for ſome time an effectual ſtop to buſineſs, and being ſoon after ſucceeded by the fire of London, the pecuniary embarraſſments of our artiſt were greater than ever, of which Leake, Jennings, Mark, and thoſe other dealers, for whom, in the courſe of the years 1666 and 67, he engraved various views and plans of London, before and after the great fire, did not fail to take advantage.

"Born to misfortune as the ſparks fly upwards," it was ſoon the fate of Hollar to turn his hopes once more toward the court, for that protection and encouragement which commerce blindly refuſed him; and in the years 1668 and 69 he was employed by government under the orders of lord Howard, to make drawings of the town and forts of Tangiers, which he afterwards engraved. In this perilous ſervice, he narrowly eſcaped being killed or made priſoner by the Turks. The ſhip, on board which he had embarked for England, the Mary Roſe, Capt. Kempthorn, fought ſeven Algerine Corſairs off Cadiz, and had eleven men killed and ſeventeen wounded; but Hollar eſcaped unhurt, and had afterwards the honour of engraving a plate of the battle.

On his return to England, he received no more for the difficulties and dangers which he had encountered, the drawings he had made, and the year he had ſpent in this arduous ſervice, than one hundred pounds; and this, according to Vertue, was not obtained till after long attendance at the public offices, and experiencing many of thoſe rebuffs "which patient merit from the unworthy takes."

From this time till the year 1677, when death put a final period to his exertions, he ſpent much of his time in travelling through the northern counties of England, and delineating and engraving their topography, and produced thoſe plates which are now objects of ſo great curioſity, and will be yet more highly valued by poſterity, as ſhewing what England was (and what Hollar was) during the reign of Charles II. The plates for Thoroton's Nottinghamſhire and Sandford's Genealogical Hiſtory, were engraved in the courſe of the three laſt years of his life.

He uſed to work for the mercenary book and printſellers at the rate of fourpence an hour, always having an hour-glaſs before him; and was ſo ſcrupulouſly exact, that when obliged to attend the calls of nature, or whilſt talking, (though with the perſons for whom he was working, and about their own buſineſs,) he conſtantly laid the glaſs on its ſide, to prevent the ſand from running. Yet notwithſtanding his exemplary induſtry, and this rigid adherence to principle; notwithſtanding his extraordinary merit as an artiſt; notwithſtanding his loyalty and the paſt favour of lord Arundel and Charles I., Hollar died poor and miſerable, after a life of viciſſitude, and for the moſt part of ſuffering.

During the diſſolute reign of the ſecond Charles, who was to liſten to the claims of modeſt and retired merit? The delighted purchaſers of his "Seleucus," after Julio Romano; his "Fountain of Pleaſures;" or his "Queen Sheba viſiting Solomon," (as will be the caſe under any reign where *patrons* are content to be acquainted with contemporary art only through the medium of paraſites and dealers,) were either heedleſs of what befel their author, or were deceived into the belief that he was at leaſt comfortably provided for; and while Stent, Overton, Green, and the reſt of the dealers of that day, enjoyed their fire-ſides in comfort, or rioted in the lap of luxury, on the profits of his works, the engraver of more than two thouſand plates, which are ſince ſought for through Europe, and moſt of which are after his own deſigns, expired in the very act of intreating the bailiffs, who had entered his wretched apartment, for a little forbearance.

Hollar's plates are for the moſt part etchings, touched here and there, where ſuperior clearneſs was wanted, or the aqua-fortis had not accompliſhed its purpoſe, with the graver. His ſmall plates are ſuperior to his larger; his ſtyle of handling his etching-needle is pleaſing, and was original; and, in the accuracy, freedom, lightneſs, ſpirit, and finiſh of his cities, abbies, cathedrals, and ſome other of his landſcapes, and his plates of natural hiſtory and ſtill life, he much excelled his contemporaries; even thoſe on the continent: but in drawing the human figure he was not equally well informed, and his hands and feet are therefore often defective.

In conformity with the falſe preference which faſhion had conferred on works performed ſolely with the graving-tool, he attempted to execute ſome plates with the graver only, but has here failed of the ſucceſs that attended him in etching.

Hollar appears to have been a meek-tempered man, and to have wanted the neceſſary confidence in his own powers or the public taſte, to venture on publiſhing any of his own engravings; though Vertue aſcribes this effect to a different cauſe, which, no doubt, was at leaſt a concomitant, he ſays, "I don't find that at any time he worked for himſelf, to ſell or publiſh, as has been cuſtomary with profeſſors of that art (engraving) when they had ſubſtance of their own, or friends and intereſt ſufficient." Alas! what is ſociety if it befriend not the ingenious.

The innate love of engraving muſt be ſtrong in ſome minds, or the neceſſity of practiſing that art muſt be imperious, for Hollar to have left ſucceſſors. The truth, however, is, that in the department of his art, in which Hollar's merit chiefly reſided, he had no ſucceſſor, for Barlow, of whom we ſhall preſently ſpeak, was an Engliſh painter, who merely learned of him the proceſs of laying etching-grounds and uſing aqua-fortis; and William Carter, Daniel King, and Thomas Dudley, who were all natives of England, and pupils of Hollar, rather followed him to the grave, than ſucceeded him in art. The former was uſed occaſionally to aſſiſt his maſter; imitated feebly his ſtyle of etching; and is the engraver of the vignette head-pieces to Ogilby's Homer, and probably of many other of thoſe anonymous book-plates that ſome collectors aſcribe to Hollar. King is ſomewhat more conſpicuous. He publiſhed "The Vale Royal of Cheſhire" from his own drawings; and engraved for Dugdale's Monaſticon, and ſome other plates of topographical ſubjects. Dudley has occaſionally ſubſcribed himſelf "quondam condiſcipulus W. Hollar," and Mr. Strutt's account of him is as follows. "He was a native of England, and one of the pupils of the famous Hollar, whoſe manner of engraving he imitated. But though he never equalled his maſter in the lightneſs of his point or freedom of execution, his etchings are not without merit. His moſt conſiderable work was a ſet of cuts for the life of Æſop, prefixed to the laſt edition of his Fables, publiſhed by Barlow. He alſo etched the portrait of biſhop Ruſſel, which is ſubſcribed Thomas Dudley Anglus fecit 1679."

R. Gaywood has alſo been mentioned as a diſciple of Hollar, but he etched no views, or other landſcapes, and in engraving portraits employed leſs of etching; and, in ſhort, did not confine himſelf to the ſtyle of that maſter, but blended with it what he acquired from ſtudying Vorſt, Vorſterman, and the other engravers of the Vandyke ſchool.

Gaywood engraved a conſiderable number of portraits, among which are thoſe of queen Mary of Scotland, with a croſs; the counteſs of Portland, Holbein, Vandyke, and Dr. Fauſtus. The only hiſtorical engraving of any conſequence from his hand is the couchant Venus of Titian, which was once in king Charles's collection, and ſince in that of the earl of Cholmondeley.

Of Francis Barlow much more may with the greateſt truth be aſſerted. This artiſt was a native of Lincolnſhire, but in what year he was born was not known. He received his firſt inſtructions in art from a portrait painter of ſmall note of the name of Shepherd, and if he learned the uſe of the engraver's inſtruments from Hollar, he formed a ſtyle for himſelf.

The inventive powers of Barlow were extremely fertile. His great merit lay in deſigning and etching quadrupeds, birds, fiſhes, inſects; in ſhort, the whole volume of animated nature appears to have been open to his view, and in this reſpect, he is the fitteſt of all men to be the companion of that great moral philoſopher Æſop, whoſe fables he has ſo admirably embelliſhed. His human figures, which with conſiderable judgment he occaſionally introduced, exhibit the dreſſes and manners of his age; he had obſerved the natural inſtincts and cuſtoms of animals, and has delineated them with a fidelity which is ſurpriſing; and his landſcape back grounds often aſſume a grandeur which could only reſult from elevated ideas of art.

His compoſitions ſhew that he had ſtudied the animal and landſcape painters who preceded him, as well as nature herſelf, with advantage. In forming his ſtyle of etching, he has evidently looked at the animals of Hollar, yet is original, vigorous, free, and ſo happily varied, as to expreſs the feathery and hairy ſurfaces of birds and quadrupeds with a degree of ſucceſs which none of his predeceſſors, and only Hollar among his contemporaries, will bear to be compared with.

The frontiſpiece to his Æſop's fables, where Æſop himſelf appears ſurrounded by animals; the angler and entreating fiſh, with its landſcape accompaniments; the proſtrate camel; the battle of the frogs and mice; and the oak, and reed bending before the ſtorm, may be mentioned with diſtinguiſhed praiſe. His foxes, camels, aſſes, and wolves, are in general moſt excellent, and all his birds are ſo, without exception: but his lions, wherever they occur, are either ideal lions, and not well conceived, or ſhew that he had once ſeen and drawn from a bad model, and repeated it wherever he had occaſion for a lion.

Part of "Monk's funeral" is Barlow's engraving: and ſeveral of the plates for Edward Benlowe's "Theophila," publiſhed in folio, A. D. 1652; and ſome of thoſe for Ogilby's Virgil, are alſo deſigned and etched by Barlow.

That at ſome period of his life he had travelled northward, may be ſeen in the print which F. Place has engraved after his drawing of "the Baſs Iſland," wherein he has introduced ſoland geeſe, curlews, gulls, and all the varieties of Northern ſea fowl; and if he ſailed thither from any port of Scotland, it was probably during this journey that he ſaw in the latter country an eagle ſoaring with a cat in its talons, of which he afterward engraved a ſpirited plate. This anecdote is recorded both by lord Orford and Mr. Strutt, who agree in ſtating that Barlow witneſſed this contention in the air whilſt he was drawing a view in Scotland, and that the cat's reſiſtance had the effect of bringing both animals to the ground.

At one period of his life, probably towards its cloſe, he reſided near the ſign of the Drum in Drury-lane. That he was induſtrious is atteſted in the great number of his productions: yet notwithſtanding this circumſtance, and the praiſe of ſuperior excellence to which he is ſo juſtly entitled: and notwithſtanding the aſſiſtance of (Mr. Strutt ſays) "a conſiderable ſum of money," (he does not ſay how much) which was left him by a friend, he died in indigent circumſtances in the year 1702.

Francis Place has ſometimes been ſpoken of as if he had learned etching of Hollar, but in a letter to Mr. Vertue he denies this; and indeed the ſtyle which he adopted and the number of plates which he has engraved after the drawings and pictures of Barlow, teaches us rather to think he muſt have ſtudied under that maſter, if under any maſter at all. Lord Orford ſays "his prints are very ſcarce," but in a book which contains "ſixty-ſeven excellent and uſeful prints of birds and beaſts" after Barlow, to which modern ſtudents and even academicians are not a little indebted, and worn impreſſions of which book may now be purchaſed of Carington Bowles for half a guinea the ſet, are twenty plates of a moderate ſize, which bear the name of Place, beſide others which on a critical inſpection may be ſeen to be from the ſame hand. The birds in theſe prints are etched with ſo much of the ſpirit and feeling of Barlow himſelf, that they might well be ſuſpected to be his own performance, but for the name of Francis Place, which is annexed; nor are his graſſy foregrounds, and the foliage and ramifications of his trees leſs excellent.

"This ingenious artiſt was the ſon of Mr. Rowland Place, of Dinſdale, in the county of Durham." When young he was articled as clerk to an attorney in London, where he continued till the year 1665, when certain officers coming to ſhut up the houſe where he reſided, on account of the plague, he took the opportunity of quitting a profeſſion that did not accord with his inclination, "and of following (ſays lord Orford) the roving life he loved, and the arts for which he had talents."

In the courſe of his various rambles, he drew, painted, and engraved, as inclination prompted or opportunity occurred, beſides diſcovering ſome occaſional diſpoſition to mineralogical reſearch, and ſkill in the manufacture of pottery.

He drew and engraved views of Tinmouth caſtle and light houſe, the cathedral of York; Scarborough caſtle, ſeveral plates for Thoreſby's Topography of Leeds, beſide various other views in England, Wales, Scotland, and Ireland, and the figures for Godartius's book of inſects.

His former biographers agree in affirming that during the reign of Charles II. he was offered a penſion of 500*l. per annum*, to draw the royal navy, but declined accepting it, having a competence without, and from his natural love of independence and diſlike of confinement. He died in the manor houſe of York in the year 1728.

Beſide the etchings which are here enumerated, and ſeveral others, Place engraved the portaits of biſhop Crewe, general Lambert, and Richard Thompſon, in mezzotinto: to treat of the diſcovery and introduction of which art, we muſt return back a few years.

Mr. Evelyn has been juſtly ridiculed by lord Orford, for the myſterious and paradoxical manner in which he announces prince Rupert's diſcovery of mezzotinto. It is, perhaps, one of the moſt honeſt, moſt candid, and moſt happily expreſſed, of the numerous pages which his lordſhip has written on the ſubject of fine art. "Ancient ſages, ſays he, uſed to wrap up their doctrines, diſcoveries or nonſenſe, in ſuch unintelligible jargon: (as Mr. Evelyn's) and the baby world, who preferred being impoſed upon to being taught, thought themſelves extremely obliged for being told any ſecret which they could not comprehend. They would be reckoned mountebanks in this age, who ſhould pretend to inſtruct without informing; and one cannot help wondering that ſo beneficent a nature as Mr. Evelyn's ſhould juggle with mankind, when the inventor himſelf had conſented that the new art ſhould be made public.

"It is a trite obſervation that gunpowder was diſcovered by a monk, and printing by a ſoldier. It is an additional honour to the latter profeſſion to have invented mezzotinto. Few royal names appear at the head of diſcoveries; nor is it ſurpriſing. One cannot expect that many of the leaſt common rank ſhould be bleſſed with uncommon abilities. Quickneſs to ſeize and ſagacity to apply are requiſite to fortuitous diſcoveries. Gunpowder, or printing, might have fallen in many a prince's way, and the world have been ſtill happy or unhappy enough not to poſſeſs thoſe arts. Born with the taſte of an uncle whom his ſword was not fortunate in defending, prince Rupert was fond of thoſe ſciences which ſoften and adorn a hero's private hours, and knew how to mix them with his minutes of amuſement without dedicating his life to theſe purſuits; (like us, who, wanting capacity for momentous views, make ſerious ſtudy of what is only the tranſitory occupation of a genius.) Had the court of the firſt Charles been peaceful, how agreeably had the prince's congenial propenſity flattered and confirmed the inclination of his uncle! How the muſe of art would have repaid the patronage of the monarch, when for his firſt artiſt ſhe would have preſented him with his nephew! How different a figure did the ſame prince make in a reign of diſſimilar complexion! The philoſophic warrior, who could relax himſelf into the ornament of a refined court, was thought a ſavage mechanic, when courtiers were only voluptuous wits. Yet if the prince was defective in the tranſient varniſh of a court, he at leaſt was adorned by the arts with that poliſh which alone can make a court attract the attention of ſubſequent ages.

"Going out early one morning during his retirement at Bruſſells, he obſerved the centinel at ſome diſtance from his poſt, very buſy doing ſomething to his piece. The prince aſked the ſoldier what he was about? he replied, the dew had fallen in the night, had made his fuſil ruſty, and that he was ſcraping and cleaning it. The prince looking at it, was ſtruck with ſomething like a figure eaten into the barrel, with innumerable little holes cloſed together like friezed work on gold or ſilver, part of which the fellow had ſcraped away.

"The *genie ſecond en experiences*, from ſo trifling an accident conceived mezzotinto. The prince concluded that ſome contrivance might be found to cover a braſs plate with ſuch a grained ground of fine preſſed holes, which would undoubtedly give an impreſſion all black; and that by ſcraping away proper parts, the ſmooth ſuperficies would leave the reſt of the paper white."

Communicating his idea to Wallerant Vaillant, a reputable painter then in the neighbourhood of Bruſſells, they made ſeveral experiments, and at laſt invented a ſteel roller with projecting points or teeth like a file, which effectually produced the black ground, and which being ſcraped away, or diminiſhed at pleaſure, left the gradations of light.

Such was the invention of mezzotinto according to lord Orford, Mr. Evelyn, and Mr. Vertue; but the baron Heinnekin affirms that "it was not prince Rupert who invented the art of engraving in mezzotinto, as Vertue and ſeveral other authors pretend to ſay; but it was the lieutenant colonel de Siegen, an officer in the ſervice of the landgrave of Heſſe, who firſt engraved in this manner; and the print which he produced was a portrait of the princeſs Amelia Elizabeth of Heſſe, engraved as early as the year 1643. Prince Rupert, he adds, learned the ſecret from this gentleman, and brought it into England when he came over the ſecond time with Charles II."

The preſent writer has not ſeen the print thus ſpoken of by the baron: and the preciſe date of prince Rupert's diſcovery is no where mentioned. But if a mezzotinto engraving dated ſeventeen years before the reſtoration can be produced, and the date be genuine, it certainly goes far toward proving Heinnekin's aſſertion. Vertue acknowledges to have ſeen an oval head of Leopold William, archduke of Auſtria, in mezzotinto, that was dated in 1656, which he eſteems the earlieſt. It is inſcribed "Theodorus Caſparus á Furſtenburgh canonicus ad vivum pinxit et fecit;" but this argues little againſt prince Rupert's diſcovery, ſince it is quite within probability that Caſparus might have learned the art from the prince or Vaillant during their reſidence in the Low Countries.

The earlieſt of Rupert's engravings in mezzotinto, that is now extant, is dated in 1658. It is an half length figure from Spagnoletto: the ſubject, an executioner holding a ſword in one hand and in the other a head, which is probably intended for that of John the Baptiſt, and upon the ſword are the initials R. P. F. ſurmounted with a coronet. It is further diſtinguiſhed by the following inſcription on a tablet beneath "SP in RVP. P. fecit. Francofurti. anno 1658 M. A. P. M."

Return we now to the hiſtorical progreſs of Engliſh *engraving*, properly ſo called; referring to the word MEZZOTINTO, for the improved modern proceſs of that branch of the art.

Lord Orford ſpeaks of William Faithorne the elder with diſtinguiſhed praiſe, and has given a tolerably correct liſt of his engravings, which he has ſeparated into five claſſes, and to which the reader, who may wiſh to arrange the works of Faithorne, is referred. He lived at the ſame period with Hollar, and about the year 1654 in the very ſame houſe; but the year of his birth has not been aſcertained. He was the diſciple of Peak, the painter and print-ſeller, who was afterwards knighted, for whom he worked three or four years. With Peak he eſpouſed the royal cauſe, when the civil wars broke out between king Charles and his parliament; and with him, and probably with Hollar alſo, was taken priſoner at Baſing-houſe; from whence he was ſent to London, and confined for ſome time in the priſon of Alderſgate. In this uncomfortable ſituation he exerciſed his ſkill as an engraver; and here he produced a ſmall head of the firſt Villiers duke of Buckingham, which is in the circular ſtyle of Mellan.

At the ſolicitation of his friends, he was releaſed from confinement, and permitted to retire to France: though Graham ſays, he was baniſhed for refuſing to take the oaths of allegiance to Cromwell, and that he ſtudied ſeveral years under Champagne.

Vertue, who received his accounts of Faithorne from Mr. W. Hill Clark, and Mr. Bagford, lord Orford's librarian, ſeems to diſcredit theſe facts; but all agree that he found protection and encouragement in France from the abbe de Marolles, and obtained improvement under the juſtly celebrated Nanteuil.

The latter indeed is ſufficiently obvious in his engravings. At his return to England, which lord Orford thinks was before the time of the protectorate, he married a ſiſter of captain Cround, by whom he had two ſons, and opened a print-ſhop oppoſite the Palſgrave-head tavern, without Temple-bar, aſſuming the ſign of the Ship. Here he not only followed his art, but ſold Italian, French, and Dutch prints, and alſo the engravings of other Engliſh artiſts; ſome of which are ſtill to be ſeen with the ſubſcription "ſold by William Faithorne." And here he appears to have remained about 30 years.

"Some time after the year 1680," ſays lord Orford, "Faithorne quitted his ſhop, and retired to a more private life in Printing-houſe yard, Blackfriars; ſtill engraving, but chiefly painting from the life in crayons, in which art he had formerly received inſtructions at Paris from Nanteuil." He alſo painted miniatures, and drew portraits in black and white. Faithorne was a robuſt and vigorous man; but the miſconduct and conſequent misfortunes of his ſon William, broke down his frame and ſpirits, and he died in the year 1691, and was interred in the church of St. Anne, Blackfriars.

The principal part of his engravings appears to have been executed during his reſidence near Temple-bar, where he alſo wrote and publiſhed a "Treatiſe on Engraving," A.D. 1662, which he dedicated to his former maſter, ſir Robert Peake. The contents of this book, as diſplayed in the title page, are as follows: "The Art of Graving and Etching, wherein is expreſſed the true way of graving on Copper; alſo, the Manner and Method of that famous Callot and Mr. Boſs, in their ſeveral ways of Etching."

Portraits conſtitute by far the moſt numerous part of this artiſt's works. He worked almoſt entirely with the graver, in a free and clear ſtyle, paying more attention to the beauty of his lines than moſt of his Britiſh predeceſſors. In the early part of his life, he ſeems to have followed the Dutch and Flemiſh manner of engraving; but on his return from France, his improvement was evidently conſiderable. His portraits are his beſt works; and the beſt of his portraits are juſtly admired for their delicacy, freedom, and force of chiaro-ſcuro.

Mr. Strutt has diſtinguiſhed the following among the more valuable of Faithorne's hiſtorical engravings: "a holy Family," from S. Vouet, a middling ſized plate, in the ſtyle of Couvy; "a dead Chriſt," from Vandyke; "the laſt Supper," without any painter's name, in folio; "Chriſt praying in the Garden," the ſame; "the Marriage of Cana in Galilee," an etching, the ſame; "the Scourging of Chriſt," from Deepenbeck. Under this latter print is written "Faithorne Sculp. Antwerp, 1657," which date ſeems to have eſcaped the notice of Vertue, and to falſify the opinion that lord Orford, on his authority, had formed, that "Faithorne returned to England before the protectorate."

His portraits, as has been already intimated, are too numerous to be detailed in this place.

William Faithorne the younger was far inferior to his father as an artiſt. His principal works are portraits, ſcraped in mezzotinto, of which Vertue has particularized about thirty, with three prints of fancy ſubjects, and a head of St. Mary Magdalen.

John Fillian was alſo a diſciple of the elder Faithorne, whoſe ſtyle and ſome of whoſe portraits he copied. He was living in 1656, but died at an early age. His principal works are, "a Head of his Maſter," looking over his ſhoulder, which is copied from a print by Faithorne himſelf; the portraits of "Thomas Cromwell," and "Paracelſus," and the "Frontiſpiece" to Heylin's Coſmography, in folio.

Of Peter Lombart, Vertue has been able to trace little, but that he came from Paris, and returned thither after remaining for ſome years in England; to which Strutt adds, that he was a native of France, and came into England before the revolution.

He worked in a neat, laboured ſtyle, and diſcovers but little taſte. His drawing is frequently incorrect; his outlines hard; his ſhadows deficient in force and boldneſs; his lights of too low a tone, and even his engravings after Vandyke are deficient in *force*, though he has diſcovered a tolerable eye for the *harmony*, of chiaro-ſcuro. Yet he worked after the pictures of the greateſt maſters: after Raphael, Guido, Pouſſin, Annibal Carracci, and Vandyke. Among the beſt of his engravings are, "the laſt Supper," a large upright, from Nicholas Pouſſin; "the Angel appearing to Joſeph," after Ph. Champagne; "the Cruciſixion," from the ſame maſter; the "Frontiſpiece," and ſeveral other plates for Ogilby's Virgil. Among his portraits from Vandyke is that of "Charles I." on horſeback, a large half-ſheet print. From this plate he afterwards eraſed the face, and ſubſtituted that of "Cromwell;" and at a ſubſequent period, "with the vicar of Bray's graver," as lord Orford wittily ſays, reſtored the king's.

Vertue has enumerated twenty other of his portraits, which are chiefly after the ſame maſter; and to them may be added a ſet of twelve half-lengths of rather a large ſize, of which ten are portraits of celebrated ladies of the court of king Charles.

Notwithſtanding his reſerve in communicating prince Rupert's diſcovery of mezzotinto, John Evelyn, eſq. of Wooton, in Surrey, is entitled to honourable mention in this place. He was the firſt Engliſh gentleman who wrote upon the ſubject of engraving; and though his "Sculptura" be deficient in artiſtical knowledge and feeling, it is a work of conſiderable erudition, and has contributed not a little to the advancement of the art; while it clearly evinces his love for engraving, the excellence of the example which he wiſhed to ſet, and the general goodneſs of his heart. Lord Orford handſomely ſays of him: "If Mr. Evelyn had not been an artiſt himſelf, as I think I can prove [that he was], I ſhould yet have found it difficult to deny myſelf the pleaſure of allotting him a place among the arts he loved, promoted, patronized; and it will be but juſtice to inſcribe his name with due panegyric in theſe records, as I have once or twice taken upon me to criticiſe him: but they are trifling blemiſhes, when compared with his amiable virtues and beneficence; and it may be remarked, that the worſt I have ſaid of him is, that he knew more than he always communicated."

The duration of the life of this great contributor to learning and the arts was protracted to 86 years, and he died in 1705.

It appears now to be agreed among the connoiſſeurs, that the five ſmall prints of Mr. Evelyn's "Journey from Naples to Rome," which his biographer thought were etched by Mr. Hoare, are Evelyn's own performances; and to theſe Mr. Strutt has added a "Portrait of Dobſon" the painter, from a picture by himſelf.

David Loggan was a native of Dantzick; he was born about the year 1635, and died in 1693. From Simon Paſs, in Denmark, he is ſaid to have received his earlieſt inſtructions in engraving; he afterwards reſided in Holland, where he ſtudied under Hondius; and a ſhort time before the reſtoration he came to England.

His drawings of All-Soul's college being taken great notice of at Oxford, he was requeſted to undertake plates of the public buildings in that univerſity. By theſe engravings he firſt diſtinguiſhed himſelf; and at Oxford he remained a conſiderable time, and married Mrs. Jordan of a good family, near Witney. In the latter part of his life he reſided in Leiceſter fields, London; where he died.

In ſatiriſing the vanity of a certain dramatic poet, Dryden ſays,

> "And in the front of all his ſenſeleſs plays,
> Makes David Loggan crown his head with bays."

Yet as Loggan's merits as an engraver were not ſuch as to crown his own with laſting reputation: his *name* will probably live much longer than his works will be cared for. He etched very little, and his ſtyle of engraving, though it has a certain degree of neatneſs, is ſtiff and taſteleſs. His portraits, of which he executed a conſiderable number, are chiefly after his own drawings in black lead, which he handled with more ability, at leaſt with a better taſte, than his graver.

Vertue has enumerated 76 portraits from the hand of Loggan, of which the principal are, three plates of "Charles II.;" "Mother Louſe of Louſe-hall," which it ſeems added much to his contemporary reputation; and "George duke of Albemarle," a half-ſheet print, and probably his beſt portrait from the life. He alſo engraved two views of "Cambridge;" a whole ſheet view of "King's "College Chapel" in that univerſity; ſeveral views of public Buildings at Oxford; and eleven plates of the "Habits of the Academics" at that univerſity, which are entitled, "Habitus Academicorum Oxoniæ à Doctore ad Servientem;" and had (what ſeems an odd thing) a licence for fifteen years for vending his "Oxonia Illuſtrata."

With David Loggan came over from Holland Abraham Blooteling and Gerard Valck, men of ſuperior talents, though probably of inferior addreſs. Vertue informs us, that whilſt in England, Blooteling received thirty guineas (a large price in thoſe days) for an etching of the duke of Norfolk. His powers were various: he etched, engraved, and ſcraped in mezzotinto. His etchings are ſpirited and free; and his mezzotintos of a clear grain, and tolerably well drawn. About eighteen of his portraits are enumerated by Vertue, of which the principal are, "Anthony earl of Shafteſbury," one of the ſcarceſt of Blooteling's works; and "Prince Rupert," after ſir P. Lely. The portrait of "Admiral Kortenaer," a large upright, from Bartholomew Vander Helſt, is not among thoſe mentioned by Vertue.

After remaining ſome few years in England, Blooteling returned to Amſterdam; and in the year 1685, publiſhed there the "Gems of Leonardo Auguſtino," from plates etched by himſelf.

Gerard Valck was originally Blooteling's ſervant, (perhaps apprentice,) but afterwards married his ſiſter. Some of the beſt engravings, or beſt parts of thoſe engravings, which were publiſhed in the name of Loggan, are probably the performances of Valck, who alſo aſſiſted Peter Schenck in his large Dutch Atlas, publiſhed in 1683. Lord Orford ſays, that he "engraved one of the fineſt prints we have: it is the famous "Ducheſs of Mazarine," ſitting in very looſe attire, with one hand on an urn;" but this praiſe is more than the engraving deſerves. His other works are, a "Bathſheba bathing," from B. Graat; and the portraits of "Robert Lord Brooke," and "John Duke of Lauderdale." Vertue knew of no other plates that were entirely engraved by Valck.

Notwithſtanding the "Sculptura" of Evelyn, and the merits of Hollar, Barlow, Faithorne, and the engravers of the Vandyke ſchool, the taſteleſſneſs and diſſolute manners of the court of Charles II. had now reduced the art of engraving to a very low ebb. Its records are ſcarcely more than thoſe of the commoneſt trade.

Edward le Davis was of Welſh extraction, and, having ſome inclination for the arts, was articled as an apprentice to David Loggan. Being maltreated by his miſtreſs, who obliged him to wear a livery, and follow her as a ſervant, he abſented himſelf, went over to France, and became a dealer in pictures. On his return he drew and engraved ſeveral portraits, and ſome other ſubjects; but their merits are inconſiderable. Vertue mentions the names of nine of theſe portraits, of which the moſt remarkable are, "King Charles II." ſeated, whoſe face was afterwards eraſed from the copper, and that of William III. ſubſtituted in its ſtead; "Queen Catherine of England," a large whole length; and "James Duke of York," a large head in an oval, ſurrounded by flowers. Le Davis alſo engraved an "Ecce Homo," after Caracci, which is become ſcarce; and "a Merry Andrew," after Frank Hals.

About the ſame time with Blooteling, Michael Burghers was alſo driven hither by the troubles in the United Netherlands, and ſettled at Oxford. His works are executed entirely with the graver, in a ſtiff, laboured ſtyle: and his drawing of the human figure very defective. The moſt valuable of his engravings are the antiquities, conſiſting of ancient pavements, ruined monaſteries, &c. which he executed for that indefatigable antiquary, Thomas Hearne. Mr. Strutt, ſpeaking of them, ſays, "though we cannot admire the taſte with which they are executed, yet they become eſtimable, becauſe they ſtill continue to us an idea of thoſe monuments of antiquity, which time had otherwiſe obliterated for ever."

Excepting theſe, his beſt prints are probably a few which he copied from Mellan, wherein he imitated the ſpiral ſtyle of that ſingular maſter, and among which are, a large "Face of our Saviour," executed in a ſingle ſpiral line; and "a Frontiſpiece" to Creech's tranſlation of the Satires of Horace, a much ſmaller plate. He alſo engraved ſome few of the "Oxford Almanacks," beginning (though the plate appears without his name) in the year 1676, and did ſeveral other plates, among which are the old chapel of Queen's college, before it was pulled down, for that learned univerſity; ſometimes adding to his name, when he inſcribed it beneath his engravings, "Academiæ Oxon. Calcographus."

Peter Vanderbank was an engraver of more merit. He was born at Paris, though probably of Dutch anceſtors. and ſtudied under De Poilly. He arrived in England about the year 1674, and here he married the ſiſter of Mr. Foreſter of Bradfield, in Hertfordſhire. Lord Orford ſays, he "was ſoon admired for the ſoftneſs of his prints, and ſtill more for the ſize of them; ſome of his heads being the largeſt that had yet appeared in England." But ſoftneſs and admiration are comparative terms; and the reader muſt not ſuppoſe that his portraits are in that reſpect comparable with thoſe of Nanteuil or Houbraken. Yet the merit of paying more attention than had hitherto been paid in England to the manual part of engraving is certainly his; and this circumſtance, added to the large dimenſions of many of his plates, occaſioned them to occupy ſo much time, that he was by no means adequately compenſated for his labour. After ſtruggling for a time with poverty, print-dealers, and the low taſte of the times, he retired without compromiſing his merits, and found an aſylum under the friendly roof of his brother-in-law at Bradfield, where he died in the year 1697.

"After his death, his widow diſpoſed of his plates to Brown, the print-ſeller, who made great advantage of them, and left an eaſy fortune."

Vanderbank engraved ſome plates after Verrio's pictures at Windſor, but by far the greater part of his works are portraits, of which Vertue has enumerated no fewer than fifty! which, conſidering the large ſize of ſome of them, is no trifling evidence of his profeſſional diligence. Thoſe of moſt importance are, "King Charles II." in his greater robes, after Gaſcar, (done the year after Vanderbank's arrival;) another portrait of Charles, two feet four inches high, by two feet wide! "King James II." after ſir Godfrey Kneller, large; "Mary his Queen," ditto; ſeparate plates of "King William" and "Queen Mary;" "Thomas Lamplugh, archbiſhop of York," which is one of the fineſt of his works; and two heads of Waller the poet, at the ages of twenty-three and ſeventy-ſix.

Arthur Soly, William Elder, John Drapentier, Robert Jackſon, Francis Bragge, Paul Vanſomer, Nicholas Yates, John Collins, Simon Gribelin, William and John Clarke, and R. Tompſon, who all lived and engraved about the time now under our obſervation, are unworthy of particular notice. "The art of engraving," ſays Vertue, "had ſunk ſo low about the cloſe of the century, that Verrio, Cooke, and Laguerre, could find no better artiſts to engrave their deſigns than Gribelin and Vanſomer." "He might in juſtice have added," obſerves lord Orford, "that the engravers were good enough for the painters."

Of Robert White, who was born in London in the year 1645, and died in 1704, little more can be ſaid, except on the ſcore of his drawings in black-lead, and his profeſſional induſtry, which, judging from the number of his engravings, may well excite our ſurpriſe. Vertue praiſes his portraits more than they will be found to deſerve as engravings. Yet all his biographers agree that the merit of producing a ſtrong likeneſs was certainly his, and in portrait engraving this is the firſt of merits.

The preſident of the Royal Academy (Mr. Weſt) is in poſſeſſion of ſome of his pencil drawings on vellum, which are ſuperior to his prints; and ſir Godfrey Kneller thought ſo well of them, that he painted White's portrait in return for drawings of his own and his brother's, from the hand of the engraver. The reader will find White's portrait of ſir Godfrey in Sandrart's lives of the painters.

From David Loggan he learned the rudiments of engraving, and in the year 1674, which is two years before Burghers was employed on the "Oxford Almanack," White produced the firſt of that ſeries.

For the generality of his portraits for books, which are diſfigured by the broad borders that were then the faſhion, he received at the rate of four pounds each, with the occaſional addition of ten ſhillings; thirty pounds, which was paid him by Mr. Sowters of Exeter for a portrait of the king of Sweden, (which the preſent writer has not ſeen, but which was probably of much larger dimenſions,) has been ſpoken of as an extraordinary price. So great, however, is the number of his engravings, that in the courſe of forty years he ſaved from four to five thouſand pounds; and yet, ſay his biographers, (with little reflection copying each other,) by ſome miſfortune or ſudden extravagance, he died in indigent circumſtances at his houſe in Bloomſbury. The reader, probably, will not readily believe, that the habits acquired by the patient profeſſional induſtry of forty years, could plunge into ſudden extravagance.

Of his own works he made no regular collection, but when he had done a plate, rolled up two or three proofs, and flung them into a cloſet, where they were found in heaps. Many of theſe proofs may now be found in the collections of thoſe curious perſons who take Grainger for their guide.

The plates which he had by him were, after his deceaſe, ſold to a printſeller in the Poultry, who in a few years, according to lord Orford and Mr. Strutt, enriched himſelf by the purchaſe. Vertue expreſſes his honeſt diſpleaſure that ſo large a portion of the produce of our engraver's induſtry ſhould devolve to the dealer; but ſo it has ever been: and if he complains for White, how loudly ſhould he complain for Milton!

The number of his portraits of which Vertue has collected the names, are two hundred and ſeventy-five, of which, two are ſcraped in mezzotinto, and all the reſt engraved in lines. Some few of Robert White's plates are finiſhed by his ſon George, who chiefly practiſed in mezzotinto, but engraved a few plates in lines, of which the principal one is a large portrait of "James Gardiner," biſhop of Lincoln.

John Sturt, the pupil of White, who was born in London in the year 1658, and lived to the age of ſeventy-two, was a man of ignorant ingenuity. His principal work is the "Book of Common Prayer," which he engraved on ſilver plates. The top of every page is ornamented with a ſmall hiſtorical vignette. Prefixed is the buſt of George I. in a circle, and facing it the prince and princeſs of Wales. The peculiarity of this work is, that the lines of the king's face are expreſſed by writing, ſo ſmall that few perſons can read it without a magnifying glaſs, and that this writing conſiſts of the Lord's prayer, the Ten Commandments, prayers for the royal family, and the 21ſt Pſalm. So that here are prayers which cannot be read, and a head which might have been better produced with a hundredth part of the labour. This *uncommon* Common Prayer Book was publiſhed by ſubſcription in London in the year 1717. It was in large octavo, and was followed by a "Companion to the Altar" of the ſame ſize, and executed in the ſame manner. Sturt was alſo the firſt man who poſed the wondering multitude of "microſcopic wights," by engraving the Lord's Prayer within the area of a circle of the dimenſions of a ſilver penny.

To this wonder-niggling ſtate was engraving reduced, when, at the commencement of the new century, ſir Nicholas Dorigny ſhone forth on the darkened arts of England. He was born in France, and was a younger ſon of Michael Dorigny, by a daughter of Vouet the painter. His father dying whilſt he was young, he was brought up to the ſtudy of the law, which he purſued till he was about thirty years of age: being then examined, in order to his admiſſion into the corps of advocates, the judge found him very difficult of hearing, and accordingly adviſed him to relinquiſh a profeſſion for which he was in this reſpect ſo ill qualified by nature. He took the advice, and immediately applied himſelf to drawing with great aſſiduity. After a year's experience in this art he repaired to Rome, where his brother at that time reſided, and here he followed painting for ſome years; when, having acquired great freedom of hand, and being uncommonly docile and flexible in his diſpoſition, he followed the recommendation of certain friends, who adviſed him to ſtudy etching. In this art he produced ſeveral works of merit, but the engravings of Audran, which were now the topic of general and juſt encomium, convinced him that the ſtyle he had adopted was ſuſceptible of great improvement; and he employed *ten years* in emulating the vigour and grandeur of that diſtinguiſhed artiſt. He had now etched many plates, and among them the ſeries from the fable of "Cupid and Pſyche," after Raffaelle, when, feeling that he had not acquired that command of the graver which was neceſſary to the harmonious perfection which he contemplated, he abandoned engraving for a ſhort time and returned to his pencils. "A word from a friend," ſays lord Orford, "would have thrown him back to the law:" this, however, it is not eaſy to believe.

After two months re-application to painting, he reſolved to acquire that power over the graver, of which he had ſo ſtrongly felt or fancied the neceſſity. All theſe feelings and reſolutions are thoſe of an artiſt of genius. With a little inſtruction, he rapidly acquired the knowledge and power of which he was in queſt, and begun to engrave the ſet of "Seven Planets," after Raffaelle; in which he ſucceeded ſo well, that he was now emboldened to undertake Raffaelle's "Transfiguration," the accompliſhment of which raiſed his reputation to an extraordinary height.

Being known to ſeveral Engliſh noblemen and gentlemen of rank, who at that time reſided in Italy, he was perſuaded to come to England, and undertake to engrave the Cartoons. He arrived in June 1711, but experienced ſome diſappointment, and was not enabled to begin his drawings till the year following, the intervening time being ſpent in raiſing a fund to enable him to proſecute his intended work.

At firſt it was propoſed that the plates ſhould be engraved at queen Anne's expence, and that the impreſſions ſhould be given as preſents to the nobility, foreign princes, miniſters, &c.; but this was too liberal even for what has been emphatically called the Auguſtan age of England, which had now commenced. Dorigny eſtimated the expences at four or five thouſand pounds, but though the lord treaſurer Orford exerted himſelf greatly in the cauſe of the artiſt, he could not obtain the ſum, and this plan was conſequently rendered abortive.

The engraver had, however, an apartment aſſigned him in Hampton Court palace, and the work was at laſt undertaken by a public ſubſcription, at four guineas the ſet.

The labour of ſeven plates of the large dimenſions that were reſolved on, appearing too great for the hand of a ſingle individual, who was not young, Dorigny was induced to ſend to Paris for aſſiſtance; and for the firſt two or three years obtained that of Dupuis and Duboſc, who both quitted him before the engravings from the Cartoons were half completed.

In ſomewhat leſs than ſeven years, however, from the date of his arrival, (namely, on the 1ſt day of April, 1719,) Dorigny had the honour of preſenting two complete ſets of theſe celebrated engravings (with an engraved dedication) to king George I., one ſet to the prince, and another to the princeſs, when he received from his majeſty a purſe of a hundred guineas, and a medal from the prince; and the duke of Devonſhire, of whom he had borrowed four hundred pounds, freely remitted the intereſt for four years. His reputation from this time continued to increaſe through Europe, and in the year following, he received the further honour of knighthood from the hand of his majeſty.

In a few years after the completion of the Cartoons, the eyes of our engraver began to grow dim, and either this circumſtance, or the natural inclination of man to return to the place of his nativity, occaſioned his return to Paris, where, in the year 1725, he was made a member of the Royal Academy of Arts, and where he died at the advanced age of eighty-nine.

His drawings from the old maſters, chiefly after Raffaelle, Dominichino, Guercino, and Daniel de Volterra, have been much admired, and have ſold for conſiderable ſums; and beſides the plates mentioned above, he engraved "St. Peter curing the lame Man," a large upright from Civoli, which is one of his early works, and in the dark manner of his father; "The Deſcent from the Croſs," after Daniel de Volterra, a very fine engraving; the "Martyrdom of St. Sebaſtian," after Dominichino, an upright, and equally meritorious; "The Holy Trinity," from Guido; and a few other plates from A. Carracci, Lanfranc, and Louis Dorigny, his brother.

When the late period of life at which Dorigny began to uſe the graver is conſidered, the power which he acquired over that inſtrument muſt be regarded as extraordinary: the art with which he mingled the lines of the graver with thoſe of the etching-needle is alſo much to be admired; and though it muſt be allowed that in copying Raffaelle's forms he has often loſt much of their exquiſite grace and chaſteneſs, and has rendered the characters of his heads but coarſely, yet on the whole he rides his graphic Pegaſus with maſculine grace. There is a manly energy and freedom in his ſtyle, bridled by ſimplicity; his ſhadows are full-toned, clear, and rich; and though his fleſh be deficient in characteriſtic texture, the lines are often conducted over his draperies with unprecedented freedom and elegance, of which the figure of "St. Paul preaching at Athens," and that of the ſame apoſtle in the Cartoon of "Elymas the ſorcerer, ſtruck blind," may be ſufficient examples. Indeed, a critical eye may trace in the arrangement of Dorigny's lines, the rudimental principle of that ſimple ſyſtem of drapery-engraving, which Mr. Heath and his ſchool have ſince poliſhed and rendered more perfect.

Charles Dupuis, who has been mentioned as the aſſiſtant of Dorigny, engraved ſome plates from the hiſtory of the misfortunes of Charles I., but the climate of England not agreeing with his conſtitution, he returned to Paris, and died there in the year 1743. A younger brother of his alſo came over, but returned in diſappointment, finding Britiſh encouragement leſs than he had expected.

Claude Duboſc quitted Dorigny's ſervice at the ſame time with Dupuis, but ſettled here, and, with more boldneſs than ability, undertook to engrave the Cartoons on a ſmaller ſcale than Dorigny's for the printſellers, who preſumptively, were *cunning* enough to think, not of tranſcending, but of *underſelling* the engravings of that diſtinguiſhed artiſt. He next engaged himſelf to engrave a ſet of the duke of Marlborough's battles, for which he received at the rate of four-ſcore pounds *per* plate. At firſt he had no aſſiſtance but what he received from du Guernier, but afterwards ſent to Paris for Beauvais and Baron, who aſſiſted him in the completion of theſe engravings. He now commenced printſeller, and publiſhed in numbers a tranſlation of Picart's "Religious Ceremonies," in engraving which, he was aſſiſted by Gravelot and Scotin, who came over to England for that purpoſe.

Duboſc's ſtyle of engraving is heavy, and his drawing of the naked very indifferent, which renders it not improbable that the worſt parts of Dorigny's Cartoons are by his hand. Among his works, which are not very numerous, the "Continence of Scipio," from that picture of Nicholas Pouſſin, which was in the Houghton Collection, is probably the beſt.

Of the Winſtanleys, as engravers, little can be ſaid. Henry (the elder) etched ſeveral views of "The Palace at Audley-end;" and Hamlet (ſon of the former) etched twenty plates from the earl of Derby's Collection, and a ſet of prints from ſir James Thornhill's "Cupola of St. Paul's Cathedral."

The father was projector and builder of the Eddyſtone light-houſe, and when it was thrown down by a dreadful tempeſt, was buried in its ruins. To his etchings of Audley-end, which were dedicated to king James II., he added an inſcription in honour of ſir Chriſtopher Wren, and the plates being "reſerved by the deſcendants of the earl of Suffolk," (according to lord Orford,) the impreſſions are now become ſcarce.

The ſon ſtudied under the Knellers, and afterwards in Italy, yet he made no great figure as an artiſt. The nobleman quoted above, ſpeaks of his houſe at Littlebury, where "were ſeveral mechanic tricks to ſurpriſe the populace, which were known by the name of "Winſtanley's Wonders." Theſe childiſh contrivances, I ſuppoſe, he learned in Italy, where they do not let their religion monopolize *all* kinds of legerdemain. In the noble palace of the villa Borgheſe," adds his lordſhip, "was the noble ſtatue of Seneca dying in the bath, and a devil that ſtarted out of a clock-caſe as you entered the room." Hamlet painted a few portraits with moderate ability.

The aſſiſtance which du Guernier rendered to Duboſc in his "Battles of the Duke of Marlborough," has been already mentioned. He ſtudied under Chatillon, at Paris, and came to England in 1708. The London Academy, as it was called, was then eſtabliſhing under the auſpices of ſir Godfrey Kneller, and du Guernier was choſen director of it, and continued to to the time of his death, which was occaſioned by the ſmall-pox, and happened Sept. 19, 1716, when he was but thirty-nine years of age. Beſides his ſhare of the Marlborough's battles, he engraved a few frontiſpieces, chiefly for plays, and, at the inſtance of lord Halifax, a large print of "Lot and his Daughter," from Caravaggio, and the portraits (large) of the "Duke and Ducheſs of Queenſbury."

Bickham, Coignard, Johnſon, George King, Nichols, and Simpſon, who were all contemporary, are paſſed over for reaſons which have formerly been given. John Kip engraved a conſiderable number of the palaces and ſeats of the nobility and gentry from Knyff, but they were indifferent, and were far from advancing the art.

It has been already mentioned, that Girard Scotin, the younger, came over from Paris to aſſiſt Duboſc. He ſtudied under his father, who was an engraver and a diſciple of De Poilly, but was a man of more induſtry than talent. His principal works are, "Beliſarius," a large plate, after Vandyke, or Murillo, for it does not appear to be aſcertained to which of theſe maſters this celebrated picture ſhould be aſcribed; and "Alfred receiving the Account of the defeat of the Danes," from Blakeney He alſo aſſiſted Hogarth in ſome of his ſeries, and engraved a few portraits.

Henry Gravelot, who came hither at the ſame time, was an artiſt of much more taſte. His opportunities of obſerving nature had been more various and extenſive than fell to the lot of many of his contemporary profeſſors of the fine arts. He was a native of France, but had been in America as ſecretary to the governor of Canada: the climate diſagreeing with him, he returned to Paris, whence he was invited to England by Duboſc.

He was for ſome time employed in Glouceſterſhire, drawing churches and antiquities, and, according to lord Orford, he drew the monuments of kings for Vertue. For the bookſellers he made a very great number of deſigns, both hiſtorical and ornamental, wherein his taſte and the fertility of his inventive powers are eminently conſpicuous. From many of theſe he made etchings, as alſo many after the deſigns of Hayman, and the ſame taſte and facility attended his etching-needle, which is conſpicuous in the productions of his pencil.

In ſir Thomas Hanmer's and Theobald's editions of Shakeſpeare, a great number of his engravings, and ſeveral of his deſigns, may be found. His principal work on copper is a large print of "Kirkſtall Abbey," which Strutt ſpeaks of as a fine ſpecimen of his abilities, but which the preſent writer has not ſeen. He lived to the age of ſeventy-four, and died at Paris in the year 1773.

Bernard Baron was alſo tranſplanted hither from the continent by Duboſc, who appears to have been a great ſpeculator in this ſpecies of culture. They differed, and went to law, on the ſubject of a ſet of engravings after Dr. Mead's pictures from the hiſtory of Ulyſſes, by Rubens, but were afterwards reconciled, and went to Paris together in the year 1729. After engraving ſome plates for Monſ.

Crozat, from the royal collection, he returned to England, and here he executed a conſiderable number, and had the ſatisfaction of working after ſome of the fineſt pictures in the kingdom.

His ſtyle is chiefly ſtudied from that of ſir Nicholas Dorigny, generally coarſe, but occaſionally ſomewhat ſoftened and incorporated with the prevailing taſte of the French ſchool. His principal engravings are as follow, and are all large plates. "Vandyke's equeſtrian figure of Charles I." from the royal gallery at Kenſington; the "Cornaro family," from the celebrated Titian at Northumberland houſe; the "Pembroke family," from the ſame maſter, at Wilton houſe; the "Naſſau family," from the ſame, in the collection of earl Cowper; the "Jupiter and Antiope," alſo after Titian, executed in Paris; "Henry VIII. granting the charter of incorporation to the company of Surgeons" from Holbein. Baron died in Panton ſquare, Piccadilly, in the year 1762.

Chereau, the younger, was alſo imported from Paris by Duboſc, and engraved a profile likeneſs of George I. which poſſeſſes ſome merit, but finding or fancying, that his talents were undervalued in England, he ſoon returned.

Michael Vandergucht, originally of Antwerp, ſtudied under Boutats, but was the maſter of Vertue. The year of his arrival in England is not known: here, however, he met with ſome encouragement, and reſided in London. His chief employment was to engrave anatomical figures, but he ſometimes undertook ſubjects of a different kind. His maſter-piece, according to Vertue, was a portrait of Mr. Savage. He alſo engraved a very large plate of the royal navy from Baſton.

John Vandergucht, ſon of the preceding, was born in 1697, and acquired from his father the manual practice of engraving, but ſtudied drawing under Lewis Cheron, and afterwards at the London Academy. He was employed by Cheſelden to draw and engrave the ſubjects for his Oſteology, a work by which he obtained much credit; and he had a conſiderable ſum for engraving "Sir James Thornhill's cupola of St. Paul's cathedral." The ſix academy figures which he engraved from the drawings of his maſter Cheron, ſhew that he underſtood drawing better than he could manage the graver. He alſo engraved Pouſſin's "Tancred and Erminia."

He produced a great number of book-plates, of which the merits were not great, and ſome were alſo engraved by his brother Gerard Vandergucht, who was a great dealer in pictures, lived to the age of eighty years, and died in 1778 at his houſe in Brook-ſtreet, the ſame that is now inhabited by Treſham the academician.

George Vertue was born in the year 1684, in the pariſh of St. Martin in the Fields, London, and was put apprentice at the age of thirteen to a maſter who engraved heraldry on plate. This perſon being obliged to leave the kingdom by the time Vertue had been three or four years under him, our artiſt returned to his parents. He then gave himſelf entirely to the ſtudy of drawing for two years, when he became the pupil of Michael Vandergucht; with whom he engaged to remain three years, but protracted his ſtay to ſeven, when he quitted his maſter on handſome terms, and begun to engrave book-plates for himſelf.

"The art was then, ſays lord Orford, at the loweſt ebb in England. The beſt performers were worn out; the war with France ſhut the door againſt recruits; and the animoſity of faction diverted public attention from the common arts of amuſement." At this period our young engraver was recommended to the notice of ſir Godfrey Kneller, whoſe reputation ſuſtained the remaining dignity of art: Kneller befriended him, and he was ſoon after employed by lord Somers, who, according to Strutt, "rewarded him generouſly," and by his talents and induſtry he was now enabled to ſupport his widowed mother, with her family of ſeveral children.

In the year 1711 he begun to ſtudy at the academy which ſir Godfrey had recently inſtituted; where he continued to draw for ſome years with great aſſiduity. He had now produced his famous head of archbiſhop Tillotſon, which lord Orford emphatically calls "the ground-work of his reputation," and ſoon after the acceſſion of the preſent royal family, he publiſhed a large portrait of king George I. from a picture by Kneller. "As it was the firſt portrait of that monarch, many thouſands were ſold, though by no means a laborious or valuable performance. However it was ſhewn at court, and was followed by his undertaking to engrave portraits of the prince and princeſs."

Vertue had now commenced thoſe biographical and antiquarian reſearches, in which he has been ſo eminently ſucceſsful. In theſe purſuits he made many journeys to different parts of our iſland, and his time was induſtriouſly employed in making drawings, catalogues, and various memoranda.

"His thirſt after Britiſh antiquities ſoon led him to a congenial Mæcenas. That munificent collector, Robert Harley, ſecond earl of Oxford, diſtinguiſhed the merit and application of Vertue;" and the invariable gratitude of the latter, expreſſed on all occaſions, atteſts at once the bounty of his patron and his own humility.

Another of his patrons was Heneage Finch, earl of Winchelſea, whoſe portrait he painted and engraved, and who, being preſident of the Society of Antiquaries on its revival, in 1717, appointed Vertue, who was a member, engraver to that learned body.

Henry Hare, the laſt lord Coleraine, was alſo one of his antiquarian benefactors, and the univerſity of Oxford employed him for many years to engrave the head pieces for their almanacks.

With lord Orford, lord Coleraine, and Mr. Stephens the hiſtoriographer, he made ſeveral tours to various parts of England. For the former he engraved portraits of "Matthew Prior," "ſir Hugh Middleton," and other diſtinguiſhed men: for the duke of Montague he engraved, "ſir Ralph Windwood;" for ſir Paul Methuen, the portraits of "Cortez," and "Archbiſhop Warham" from Holbein's original at Lambeth; and for lord Burlington, Zucchero's "Queen Mary of Scotland," a plate which evinces more felicity, and a better taſte of execution, than moſt other of his works.

In the year 1727 he travelled with lord Orford to Burleigh, Lincoln, Welbeck, Chatſworth, and York, at which latter place he obtained from Francis Place, whom we have mentioned, many of thoſe anecdotes of Hollar which are inſerted in his biography.

In the next year, the duke of Dorſet invited him to Knowle. From the gallery there, he copied the portraits of ſeveral of the poets. Here he was on fairy ground, and Arcadia was on the confines; but he was diſappointed on an excurſion to Penſhurſt, at not finding there any portrait of ſir Philip Sydney.

In 1730 appeared his twelve heads of diſtinguiſhed poets, one of his capital works, which he meant to have followed with the portraits of other eminent men, arranged in claſſes, but this ſcheme was taken out of his hands by the Meſſrs. Knapton; and there is reaſon to think that Vertue's rigid regard for veracity, which made him juſtly ſcrupulous of authenticating the likeneſſes of deceaſed characters without the cleareſt proofs, and not the ſuperior taſte or diſcernment of the Knapton's, made them engage the ſuperior talents of Houbraken and Gravelot, to finiſh a work which our artiſt had begun, and had himſelf projected.

His next conſiderable production was, the portraits of king Charles I. and the loyal ſufferers in his cauſe, with their characters ſubjoined from Clarendon. But this was ſcarcely finiſhed, before Rapin's hiſtory of England appeared, “a work, (ſays he,) which had a prodigious run, inſomuch that it became all the converſation of the town and country, and the noiſe being heightened by oppoſition and party, it was propoſed to publiſh it in folio by numbers, of which thouſands were ſold every week.” The Meſſrs. Knapton engaged Vertue to accompany it with effigies of the kings and other ſuitable embelliſhments, an undertaking which occupied three years of his life. He preſented a copy of this work, when finiſhed, richly bound, to the prince of Wales, at Kenſington.

He now renewed his topographical journies, accompanied ſometimes by the earl of Leiceſter, ſometimes by lord Oxford, and ſometimes by Roger Gale the antiquary; and between the years 1734-38, viſited St. Albans, Northampton, Oxford, Penſhurſt, Warwick, Coventry, Stratford, and travelled through the counties of Kent, Suſſex, and Hampſhire, where he made various ſketches, drawings, and notes, always preſenting a duplicate of his obſervations to his patron lord Oxford.

In 1739, he travelled eaſtward with lord Coleraine, through the counties of Eſſex, Suffolk, and Norfolk, ſtopping as uſual to make drawings and obſervations at every memorable church, ſeat, or other ſpot congenial to his purſuits. In 1741 he loſt his noble friend and patron the earl of Oxford, who died on the 16th of June. But his merit and modeſty ſtill raiſed him benefactors. The counteſs dowager of Oxford, even, alleviated his loſs, and the ducheſs of Portland (their daughter), the duke of Richmond, and lord Burlington, did not forget him among the artiſts whom they patronized.

In the year 1749, he found a yet more exalted protector in the prince of Wales, whom he often had the honour of attending, and to whom he ſold many prints, miniature pictures, &c.

“He had now reaſon to flatter himſelf with permanent fortune. He ſaw his fate linked with the revival of the arts he loved; he was uſeful to a prince who trod in the ſteps of the accompliſhed Charles, and no Hugh Peters (adds lord Orford) ſeemed to threaten havoc to the growing collection.” But the death of this prince ſuddenly blaſted the hopes of Vertue, and affected him with conſiderable dejection of ſpirits, from which, according to his lordſhip, he never perfectly recovered. He died in the year 1756, and was buried in the cloiſters of Weſtminſter abbey.

By the majority of connoiſſeurs, Vertue's talents as an engraver have been over-rated. He rarely riſes above mediocrity, and ſometimes ſinks below it, yet the preſent writer muſt freely declare his ſurpriſe when he firſt ſaw a good impreſſion of Vertue's print of “Mary Queen of Scotland,” after Zucchero, at the ſuperior merits which it diſplayed.

A much more copious biography of this artiſt will be found in the printed works of lord Orford, and alſo a catalogue of his engravings (amounting to near five hundred!) claſſed under the heads of “Royal Portraits,” “Noblemen,” “Biſhops,” “Poets,” “Antiquaries,” “Tombs,” “Hiſtoric Prints,” “Coins,” “Medals,” “Frontiſpieces,” &c. &c. &c.

To all the diſtinguiſhed notice and patronage with which Vertue was honoured, and to the repeated praiſe of lord Orford, who was one of his friends, he was entitled leſs by his talents as an artiſt, or native independence of mind, than by his patience and accuracy of reſearch as an antiquary, and as his noble biographer cannot boaſt of his genius, it might, perhaps, have been thought that he did right to dwell with ſo much ſeeming approbation on his diligence and humility; if he had not himſelf left poſterity ſuch abundant room to wiſh that he had reſpected genius more, and been leſs completely ſatisfied with the blandiſhments, which plodding mediocrity may with little difficulty acquire.

We now approach the leſs patronized and more highly reſpectable name of William Hogarth, upon whoſe valuable works as painter and engraver, ſo many volumes might be profitably written. The able pen to which the biography of the former deſcription of artiſts is confided, will doubtleſs claim Hogarth as a painter, yet, as he was both by education and long practice an engraver alſo, he muſt not here be paſſed in ſilence.

In the narrative which he left behind of his own life and opinions, where his philoſophy is not leſs conſpicuous than his manly frankneſs, and where his foreſight with reſpect to the well-being of Britiſh art has ſhewn itſelf prophetic, he informs us, that he was born in London in the year 1697; that during his infancy he derived uncommon pleaſure from ſhews and mimickry; that an early acceſs to a neighbouring painter drew his attention from play; and that when at ſchool his exerciſes were remarkable for the ornaments with which they were adorned.

He was ſcarcely more attracted by art, than driven from literature, which was the profeſſion of his father. “Beſides the natural turn I had for drawing,” proceeds he, “I had before my eyes the precarious ſituation of men of claſſical education. I ſaw the difficulties under which my father laboured, and the many inconveniences he endured from his dependance being chiefly on his pen, and the cruel treatment he met with from bookſellers and printers. It was, therefore, very conformable to my own wiſhes that I was taken from ſchool, and ſerved a long apprenticeſhip to a ſilver-plate engraver.

“I ſoon found this buſineſs in every reſpect too limited. The paintings of St. Paul's cathedral and Greenwich hoſpital, which were at that time going on, ran in my head, and I determined that ſilver-plate engraving ſhould be followed no longer than neceſſity obliged me to it.

“Engraving on copper was, at twenty years of age, my utmoſt ambition. To attain this it was neceſſary that I ſhould learn to draw objects ſomething like nature, inſtead of the monſters of heraldry, and the common methods of ſtudy being much too tedious for one who loved his pleaſure, I was led to conſider whether a ſhorter road than that uſually travelled was not to be found. I had learned by practice to copy with tolerable exactneſs in the uſual way; but it occurred to me that there were many diſadvantages attending this method of ſtudy, as having faulty originals,” &c. Drawing in an academy, (Hogarth means a ſchool,) though it ſhould be after the life, will not make the ſtudent an artiſt, for as the eye is often taken from the original to draw a bit at a time, it is poſſible he may know no more of what he has been copying when his work is finiſhed, than he did before it was begun.

“More reaſons, not neceſſary to enumerate, ſtruck me as ſtrong objections to this practice, and led me to wiſh that I could find the ſhorter path, fix forms and characters in my mind, and inſtead of copying the lines, try to read the language, and if poſſible find the grammar of the art, by bringing into one focus the various obſervations I had made, and then trying, by my power on the canvas and copper, how far my plan enabled me to combine and apply them to practice.

“ For this purpoſe, I conſidered what various ways, and to what different purpoſes the memory might be applied; and fell upon that which I found moſt ſuitable to my ſituation and idle diſpoſition.

“ Laying it down firſt as an axiom, that he who could by any means acquire and retain in his memory perfect ideas of the ſubjects he meant to draw, would have as clear a knowledge of the figure as a man who can write freely hath of the twenty-four letters of the alphabet and their infinite combinations (each of them being compoſed of lines), and would conſequently be an accurate deſigner.

“ This I thought my only chance for eminence, as I found that the beauty and delicacy of the ſtroke in engraving was not to be learnt without much practice, and demanded a larger portion of patience than I felt myſelf diſpoſed to exerciſe. Added to this, I ſaw little probability of acquiring the full command of the graver in a ſufficient degree to diſtinguiſh myſelf in that walk, nor was I at twenty years of age much diſpoſed to enter on ſo barren and unprofitable a ſtudy as that of merely making fine lines.

“ I therefore endeavoured to habituate myſelf to the exerciſe of a ſort of technical memory, and by repeating in my own mind the parts of which objects were compoſed, I could by degrees combine and put them together. Thus, with all the drawbacks which reſulted from the circumſtances I have mentioned, I had one material advantage over my competitors, *viz.* the early habit I thus acquired of retaining in my mind's eye whatever I intended to imitate. Sometimes, but too ſeldom, I took the life for correcting the parts I had not perfectly enough remembered, and then I transferred them to my compoſitions.”

Such parts only of Hogarth's valuable narrative as are to the preſent purpoſe, are here extracted. Thoſe who would read the whole are referred to “ A ſupplement to Hogarth illuſtrated, compiled from his original manuſcript by John Ireland,” 1798, publiſhed for the author by Nicol, and the Meſſrs. Boydell. Our artiſt proceeds:

“ Inſtead of burthening the memory with muſty rules, or tiring the eyes with copying dry and damaged pictures, I have ever found ſtudying from nature the ſhorteſt and ſafeſt way of attaining knowledge in art.”—“Had I not ſedulouſly practiſed what I thus acquired, I ſhould very ſoon have loſt the power of performing it.”

In a ſubſequent chapter he ſays, “ in purſuing my ſtudies, I made all poſſible uſe of the technical memory which I have before deſcribed, by obſerving and endeavouring to retain in my mind lineally, ſuch objects as beſt ſuited my purpoſe, ſo that be where I would my eyes were open, I was at my ſtudies, and acquiring ſomething uſeful in my profeſſion, and thus the more ſtriking objects, whether of beauty or deformity, were by habit the moſt eaſily impreſſed and retained in my imagination. A redundancy of matter being by this means acquired, it is natural to ſuppoſe I introduced it into my works on every occaſion that I could.

“ By this idle way of proceeding, I grew ſo profane as to admire nature beyond the firſt productions of art, and acknowledge I ſaw, or fancied, delicacies in the life, far ſurpaſſing the utmoſt efforts of imitation.

“ To return, the inſtant I became maſter of my own time, I determined to qualify myſelf for engraving on copper. In this I readily got employment; and frontiſpieces to books, prints to Hudibras, &c. ſoon brought me into the way. But the tribe of bookſellers remained as my father had left them when he died, (about five years before,) which was of an illneſs occaſioned partly by the treatment he met with from this ſet of people, and partly by diſappointment from great men's promiſes; ſo that I doubly felt this uſage, which put me upon publiſhing on my own account. But here again I had to encounter a monopoly of printſellers, equally mean and deſtructive to the ingenious; for the firſt plate I publiſhed, called “ The Taſte of the Town,” had no ſooner begun to take a run, than I found copies of it in the print-ſhops vending at half price, while the original prints were returned to me again, and I was thus obliged to ſell the plate for whatever theſe pirates pleaſed to give me, as there was no place of ſale but at their ſhops. Owing to this and other circumſtances, by engraving until I was near thirty, I could do little more than maintain myſelf.”

At the age of two and thirty, he married the daughter of ſir James Thornhill, and commenced painter of ſmall converſation pieces, which, having novelty, ſucceeded for a few years, but were afterwards not ſufficiently profitable to pay the expences of his family. “ I therefore,” ſays he, “ turned my thoughts to a ſtill more novel mode, *viz.* painting and engraving modern moral ſubjects, a field not broken up in any country or any age.

“ I thought that both writers and artiſts had overlooked that intermediate ſpecies of ſubject, which may be placed between the ſublime and the groteſque; I therefore wiſhed to compoſe pictures on canvas, ſimilar to repreſentations on the ſtage.

“ Ocular demonſtration will carry more conviction to the mind of a ſenſible man than all he would find in a thouſand volumes; and this has been attempted in the prints which I have compoſed.

“ After having had my plates pirated in almoſt all ſizes, I, in 1735, applied to parliament for redreſs, and obtained it in ſo liberal a manner, as hath not only anſwered my own purpoſe, but made prints a conſiderable article in the commerce of this country; there being now more buſineſs of this kind done here, than in Paris or any where elſe.

“ The dealers in pictures and prints found their craft in danger, by what they called a new-fangled innovation. Their trade of living and getting fortunes by the ingenuity of the induſtrious has, I know, ſuffered much by my interference; and if the detection of this band of public cheats and oppreſſors of the riſing artiſts be a crime, I confeſs myſelf moſt guilty.”

The obtainment of this act, which ſecures the copy-right of engravings, was certainly a great benefit, not only to artiſts, but to the public, and even to the print dealers themſelves, who now were ſecured in the poſſeſſion of any engraved property which they might purchaſe. The remainder of Hogarth's narrative chiefly reſpects his profeſſion as a painter, and the incidents of his private life. His reputation was now extending far and wide: he had publiſhed his “ Harlot's Progreſs” in ſix plates, beſide many other prints of leſs importance, which Mr. Ireland has enumerated, and now brought forth his “ Rake's Progreſs” in eight, which are replete with moral leſſon and the moſt pointed ſatire. Swift about this time wrote

> “ How I want thee, hum'rous Hogarth!
> Thou, I hear, a pleaſant rogue art,
> Were but you and I acquainted
> Ev'ry monſter ſhould be painted:
> You ſhould try your graving tools
> On this odious group of fools, (the Legion Club.)
> Draw the beaſts as I deſcribe 'em,
> Form their features, while I gibe 'em.”

In the courſe of the next year he engraved “ The Sleeping Congregation ;” “ The Diſtreſſed Poet,” which in its original ſtate repreſents Pope thraſhing the bookſeller Curl, and “ The Arms of the Undertaker's Company.” He alſo publiſhed a whole length portrait of lady Byron, from a picture of his own, engraved in mezzotinto by Faber.

In the year 1737, he produced only “ The Lecture.” In 1738, he publiſhed “ Morning,” “ Noon,” “ Evening,” and “ Night.” The third plate was engraved by Baron, except the figure of the girl with a fan, which was an afterthought of Hogarth's, and is from his own graver. The “ Saliſbury” flying coach in the engraving of Night, is thought to be a ſatire on a certain peer who delighted to drive his own horſes. He alſo produced this year “ Strolling Actreſſes in a Barn ;” the original picture of which he ſold to Francis Beckford, eſq. for 27*l.* 6*s.* who returned it, though charged at ſo low a price, and it was afterwards ſold to Mr. Wood of Littleton for the ſame ſum.

Until the year 1741, he publiſhed nothing more, when “ The enraged Muſician” made its appearance, in which the principal figure has been ſpoken of as being the portrait of Cervetto, but on better authority, is now ſuppoſed to be that of Feſtin.

In 1742, he engraved and publiſhed the portrait of “ Martin Foulkes, eſq.” “ The Charmers of the Age,” (a ſketch,) and “ Taſte in High Life,” which latter is replete with the moſt pointed ſatire on the reigning follies and faſhions which then prevailed in the higher circles. A more ſophiſticated aſſemblage of objects cannot be imagined, and the elderly lady of the Cheſterfield ſchool, who holds the ſmall Dreſden tea-cup with ſo much exquiſite delicacy of fingering, and a countenance ſo truly expreſſive of the affectation of intenſe enjoyment of its beauties, has never been ſurpaſſed.

From this time, till the year 1745, he was employed on his “ Marriage A-la-Mode,” and only publiſhed three portraits, engraved by other artiſts, from his own pictures. The ſeries of ſix plates of the Marriage A-la-mode were chiefly engraved by Scotin and Baron, who have been already mentioned, and S. Ravenet. Hogarth engraved on the plates from time to time, which has occaſioned thoſe variations which certain adorers of rarity look for with more eagerneſs, than they appear to poſſeſs feeling or judgment in eſtimating the general deſign. This ſeries comprehends indeed maſter-pieces of art in their kind, and places Hogarth's fame on the broadeſt and moſt durable baſis.

In the following year, he etched and publiſhed his characteriſtic portrait of “ Lord Lovat,” which, by thoſe who have ſeen him, has been atteſted to be “ in air, character, and features, a moſt faithful reſemblance of the original.” He is repreſented ſeated in his old faſhioned chair with the lofty back, and in the act of enumerating by his fingers the rebel forces. It is etched with uncommon ſpirit, and what was of more pecuniary importance, (adds Mr. Ireland,) was ſo well timed, that Mrs. Lewis told me, they for many weeks received more than ten pounds a day from the ſale. It was publiſhed the 25th Auguſt, 1746, and the peer was beheaded the 9th April 1747, in the eightieth year of his age. The portrait of Garrick, in the character of Richard III. engraved by Hogarth, and C. Grignion, was alſo publiſhed this year, of which Mr. Grignion, (who has done ſo much for an art which has done ſo little for him, and is ſtill living,) ſays, that Hogarth etched the head and the hands, but eraſed the head twice before he could ſatisfy himſelf. In the courſe of the preſent year Hogarth alſo iſſued the ſubſcription ticket to “ The March to Finchley.”

The ſeries of “ The Idle and Induſtrious Apprentices,” in twelve plates, deſigned and engraved by William Hogarth, were publiſhed in 1747. Of this ſeries, ſo replete with moral leſſon, and heightened with ſuch admirable ſtrokes of humour, Hogarth himſelf has written as follows. “ The effects of idleneſs and induſtry exemplified in the conduct of two fellow-'prentices. Theſe twelve prints were intended for the inſtruction of young people, and, conſidering the perſons they were intended to ſerve, I have endeavoured to render them intelligible and cheap as poſſible :” (the twelve were originally publiſhed at the low price of twelve ſhillings.) “ Fine engraving is not neceſſary for ſuch ſubjects, if what is infinitely more material, *viz.* character, and expreſſion, be properly preſerved.” “ The Stage Coach or Country Inn Yard,” and two portraits of Gibbs the architect, engraved by Baron and Mc. Ardell, he alſo publiſhed in the courſe of this year.

In 1748, he etched a view of Mr. Ranby's houſe at Chiſwick, but nothing elſe of any conſequence. In 1749, was produced “ The Gate of Calais,” or, “ Roaſt Beef of Old England.” It appears that ſoon after the peace of Aix-la-Chapelle, Hogarth went over to France, and as he was ſauntering about at Calais, and contemplating the difference between England and France, he obſerved over the gate of the town ſome appearance of the arms of England ; he was prompted to make a ſketch, and being obſerved, was taken into cuſtody : his own account of this affair is as follows : “ Not attempting to cancel any of my ſketches or memorandums, which were found to be merely thoſe of a painter for his private uſe, without any relation to fortification, it was not thought neceſſary to ſend me back to Paris.” (This word contradicts the aſſertion of thoſe who ſay he never went further into France than Calais.) “ I was only cloſely confined to my own chamber till the wind changed for England ; where I no ſooner arrived, than I ſet about the picture (of roaſt beef) and made the gate my back ground ; and in one corner introduced my own portrait, which has generally been thought a correct likeneſs, with the ſoldier's hand upon my ſhoulder. By the fat friar, who ſtops the lean cook that is ſinking under the weight of a vaſt ſurloin, and two of the military who are bearing off a great kettle of ſoup maigre, I meant to diſplay to my own countrymen the ſtriking difference between the food, prieſts, ſoldiers, &c. of two nations ſo contiguous, that in a clear day one coaſt may be ſeen from the other. The melancholy and miſerable highlander, browzing on his ſcanty fare, conſiſting of a bit of bread and an onion, is intended for one of the many that fled from this country after the rebellion in 1744.” In the courſe of this year, he alſo engraved and publiſhed his own portrait in a cap, with his favourite pug dog and palette, on which is drawn that myſterious “ line of beauty and grace,” which excited, and was meant to excite, the attention of the public in no ſlight degree.

Fourteen years afterwards, Hogarth eraſed his own head from the plate, and in its place engraved a caricature of Churchill as a bear, and inſcribed it, “ The Bruiſer C. Churchill (once the Reverend !) in the character of a Ruffian Hercules,” &c. &c.

In the year 1750, appeared his “ March to Finchley,” which was engraved by Luke Sullivan, and dedicated to the king of Pruſſia. The original picture he preſented to the Foundling hoſpital. “ Gin-lane” and “ Beer-ſtreet” appeared in the following year, of which prints Hogarth himſelf gives the following account. “ When theſe two prints were deſigned and engraved, the dreadful conſequences of gin drinking appeared in every ſtreet. In Gin-lane, every circumſtance of its horrid effects is brought to view *in ter-*

rorem. Idleneſs, poverty, miſery, and diſtreſs, which drive even to madneſs and death, are the only objects that are to be ſeen; and not a houſe in tolerable condition, but the pawn-brokers and gin ſhop."

"Beer-ſtreet," its companion, was given as a contraſt, where that invigorating liquor is recommended in order to drive the other out of vogue. Here all is joyous and thriving, &c. &c."

He alſo now publiſhed his "Four Stages of Cruelty," of which he has thus uſefully, honeſtly, and proudly written. "The leading points in theſe, as well as the two preceding prints, were made as obvious as poſſible, in the hope that their tendency might be ſeen by men of the loweſt rank. Neither minute accuracy of deſign, nor fine engraving, were deemed neceſſary, as the latter would have rendered them too expenſive to the perſons to whom they were intended to be uſeful: and the fact is, that the paſſions may be more forcibly expreſſed by a ſtrong bold ſtroke, than by the moſt delicate engraving." (The artiſt probably meant this obſervation to be applied to the violent, and not to the tender paſſions.) "To expreſſing them as I felt them, I have paid the utmoſt attention, and as they were addreſſed to hard hearts, have rather preferred leaving them hard, and giving the effect by a quick touch, to rendering them languid and feeble by fine ſtrokes and ſoft engraving, which require more care than can often be attained, except by a man of a very quiet turn of mind. Maſſon, who gave two ſtrokes to every particular hair that he engraved, merited great admiration, but at ſuch admiration I never aſpired, neither was I capable of attaining it if I had.

"The prints were engraved with the hope of, in ſome degree, correcting that barbarous treatment of animals, the very ſight of which renders the ſtreets of our metropolis ſo diſtreſſing to every feeling mind. If they have had this effect and checked the progreſs of cruelty, I am more proud of having been the author, than I ſhould be of having painted Raphael's cartoons."

The humorous "Paul before Felix" was alſo the produce of this year, which in the earlieſt impreſſions is ſubſcribed, "deſigned and ſcratched in the true Dutch taſte by William Hogarth," and in the ſubſequent impreſſions (where he has introduced a little fiend ſawing off the leg of the Apoſtle's ſtool,) "deſigned and etched in the ridiculous manner of Rembrandt by Wm. Hogarth." This whimſical little print was originally given with the receipts to the ſubſcription for the ſerious "Paul before Felix," and "Pharoah's Daughter," both of which he produced in the courſe of the enſuing year.

The former of theſe he engraved from his original picture in Lincoln's-inn Hall; another plate of which ſubject, with ſome variations, was publiſhed by Hogarth at the ſame time, (which is remarkable, both being dated Feb. 5,) engraved by Luke Sullivan.

"Moſes brought to Pharaoh's Daughter" is engraved by William Hogarth and Luke Sullivan from the original painting in the Foundling hoſpital, and was alſo publiſhed on the ſame day.

His "Columbus breaking the Egg" was given in the November of this year, with the receipt for "the firſt payment of a ſhort tract in quarto, called the Analyſis of Beauty; wherein forms are conſidered in a new light;" and in the next year came forth his far famed "Analyſis of Beauty, written with the view of fixing the fluctuating ideas of taſte," and embelliſhed with two folded and very curious illuſtrative engravings.

With ſome ſmall literary aſſiſtance from Dr. Hoadly, Mr. Ralph, and Dr. Morell, he here maintained an hypotheſis reſpecting undulating forms as eſſential to grace and beauty, the merits of which have, by ſubſequent writers on the ſubject of taſte, been variouſly eſtimated, but of late have been utterly denied by Mr. P. Knight, who (in his analytical enquiry into the principles of taſte) ſays, that the qualities of eaſe, grace, elegance, &c. do not "conſiſt in any lines of beauty, or depend upon the impreſſions which any ſpecific forms make on the organs of ſight. On the contrary, they ariſe wholly from mental ſympathies and the aſſociation of ideas."

An impreſſion from the firſt plate of the Analyſis of Beauty, which is in the poſſeſſion of Mr. G. Baker, has this ſingularity, that the words "et tu Brute," are engraved on the pedeſtal on which ſtands Quin in the character of Brutus, which were afterwards eraſed.

In the year 1754 his admirable ſatire on parliamentary elections, which was engraved on four plates, began to appear. Of the firſt plate, which is "An Election Entertainment," it has been ſaid that Hogarth completed the engraving without taking from it a ſingle proof by which to aſcertain the progreſs of his work. It might be ſo, but if this were wiſe it would more frequently be practiſed, and Hogarth himſelf is known to have repented of his imprudence when a proof was taken.

This performance, in its original ſtate, is by far the moſt finiſhed and carefully executed of Hogarth's engravings, and he therefore, conſcious of the ſuperior pains which he had beſtowed on it, inſcribed beneath it, "painted, and *the whole* engraved by Wm. Hogarth," but theſe two words were afterwards eraſed, for the number ſold was ſo conſiderable, that by the time the ſecond plate of this ſeries made its appearance, the firſt had been touched and retouched ſo often, that all the original and delicate lines were either hidden by others, or utterly obliterated, and it has been compared, wittily enough, to ſir John Cutler's ſtockings, which, from frequent mending, from ſilk degenerated into worſted.

The ſecond of the election ſeries, of which the ſubject is "Canvaſſing for Votes" is engraved by C. Grignion, and was publiſhed in the year 1757. On which occaſion Hogarth apologized in the public prints for the delay which had taken place, aſcribing it to the difficulty of procuring able hands to engrave the plates. In the early impreſſion this is an excellent engraving.

The third plate of this ſeries is entitled "The Polling," is engraved by Hogarth and Le Cave, and was publiſhed in the following year.

The fourth plate, which completes the ſeries, and is entitled "Chairing the Members," was alſo publiſhed in the courſe of the year 1758, and is engraved by Hogarth and Aveline.

In all theſe plates the ſatire of Hogarth is moſt poignant and abundant; and notwithſtanding the number of portraits our engraver has introduced, his meaning is ſo general, that the election-prints continue to be applicable to the preſent time.

In the year 1758 he alſo engraved and publiſhed "the Bench," with explanations and illuſtrations of the words, "character" and "caricature." The print exhibits the inſide of the court of common pleas, over which is the king's arms, and beneath are the portraits of the following judges, *viz.* honourable William Noel, ſir John Willes; the lord chief juſtice; honourable Mr. juſtice (afterwards lord) Bathurſt, and ſir Edward Clive.

His own portrait, a whole length figure, was alſo the produce of this year, in which plate the face only is engraven by Hogarth. He has here repreſented himſelf in profile, ſitting, with a cap on his head, and engaged, in a very appropriate manner, in painting the muſe of comedy. His analyſis of beauty lies on the floor, and underneath is his title of ſerjeant painter to his majeſty. It may be obſerved of this likeneſs, and that which he has introduced in his "Gate of Calais," that they both correſpond much better with the buſt of Hogarth, which was modelled by Roubilliac, and is now in the collection of M. G. Baker, than the three-quarter face which was publiſhed in 1749, and afterwards metamorphoſed to that of Churchill the poet.

"The Cockpit," deſigned and engraved by W. Hogarth, was produced in 1759. In this engraving is introduced a portrait of Nan Rawlins, a very ugly old woman (commonly called Deptford Nan, and ſometimes the ducheſs of Deptford), who is well remembered at Newmarket. She was a famous cock-feeder, and did the honours of the gentlemens' ordinary at Northampton. The figure with the hump back is that of Jackſon, a once noted jockey, and the blind preſident is lord Albemarle Bertie, who conſtantly attended this refined and elegant diverſion.

In the next three years he produced nothing of his own engraving, though he made ſome deſigns from Triſtram Shandy; one for Brook Taylor's perſpective, and a few others, which were engraved by Woollett, Ravenet, and Grignion: but in 1762, he produced his "Credulity, Superſtition, and Fanaticiſm," which is chiefly meant to ridicule certain methodiſtical ſectaries, and is preferred by lord Orford to all his other works "for deep and uſeful ſatire."

"The Times" was alſo produced in the year 1762. This is a political print, which Mr. Nichols explains as follows: "Europe on fire; France, Germany, and Spain, in flames, which are extending to Great Britain. This deſolation continued and aſſiſted by Mr. Pitt under the figure of king Henry VIII. with bellows encreaſing the miſchief which others are ſtriving to abate. He is mounted on the ſtilts of the populace. A Cheſhire cheeſe depends from his neck with 3,000*l.* on it. This alludes to what he had ſaid in parliament, that he would ſooner live on Cheſhire cheeſe and a ſhoulder of mutton, than ſubmit to the enemies of Great Britain. Lord Bute, attended by Engliſh ſoldiers, ſailors, and highlanders, manages an engine for extinguiſhing the flames, but is impeded by the duke of Newcaſtle with a wheel-barrow full of monitors and North Britons, for the purpoſe of feeding the blaze. The reſpectable body under Mr. Pitt are the aldermen of London worſhipping the idol they had ſet up; whilſt the muſical king of Pruſſia, who alone is ſure to gain by the war, is amuſing himſelf with a violin amongſt his miſerable country women. The picture of the Indian alludes to the advocates for retaining our Weſt Indian conqueſts, which it was ſaid would only increaſe exceſs and debauchery. The breaking down of the Newcaſtle arms, and the drawing up the patriotic ones, refer to the reſignation of that noble duke, and the appointment of his ſucceſſor. The Dutchman ſmoking his pipe and a fox peeping out behind him and waiting the iſſue; the waggon with the treaſures of the Hermione; the unneceſſary marching of the militia, ſignified by the Norfolk jigs; the dove with the olive branch, and the miſeries of war, are all obvious, and perhaps need no explication."

In 1763, he publiſhed a caricature of "John Wilkes," eſquire, drawn from the life, and etched in aquafortis by William Hogarth. To which was ironically added "this is a direct contraſt to the print of Simon lord Lovat."

Of this caricature, Wilkes with his uſual good humour has been heard to ſay, that he was every day growing more and more like his portrait by Hogarth.

In the ſame year was publiſhed alſo, "the Bruiſer C. Churchill," which has been already mentioned, and which neither added to his fame, nor in its conſequences to his happineſs.

"The Bathos," publiſhed in 1764, was his laſt engraving of any conſequence, if not his very laſt work. In the month of October of this year being ſeventy-four years of age, he departed this life, and was buried in the church yard of Chiſwick, where a monument, with an excellent epitaph by Garrick, is erected to his memory.

His engravings, like the tenour of his life, are characterized not by delicacy, but by ſtrength of thought and expreſſion. He did not aim at captivating by the beauty of his art, but at excelling by the power which he poſſeſſed of combining a number of particular and congenial truths into one impreſſive whole: agreeably to his own declarations, we perceive in his prints, that he diſcovers little dexterity in the arrangement of his lines, and ſtill leſs ſolicitude about their beauty: yet in his pictures, and eſpecially in thoſe of the Marriage A-la-Mode, now in the collection of J. J. Angerſtein, eſquire, are ſome paſſages which no Dutch painter and no other painter could have more exquiſitely touched. No artiſt whatever, and ſcarcely any man more than Hogarth, deſerves the praiſe of original and independent thinking. His engravings are in ſome inſtances taken from no pictures, and his pictures from no books. Without having recourſe to hiſtory or poetry he *invented* his ſubjects. The world of moral art "was all before him where to chooſe:" he marked out and took poſſeſſion of an ample province for himſelf, replete with the riches of nature; a province which few have ſince dared to invade, and to which none have diſputed his title.

Luke Sullivan, who has been already mentioned, was Hogarth's moſt valuable coadjutor in engraving. He was a native of Ireland, an eccentric character, and much addicted to women. Whilſt engraving the march to Finchley (according to Mr. Ireland,) "Hogarth held out every poſſible inducement to his remaining at his houſe in Leiceſter-ſquare night and day; for if once Luke quitted it he was not viſible for a month." If Hogarth gave him but one hundred pounds for this plate, as his biographers ſay, Sullivan's inducements to ſtay at home were certainly ſtrong.

Beſide what he did after Hogarth, Sullivan engraved "the Temptation of St. Anthony," after Teniers, and ſeveral garden ſcenes and other landſcapes, which he drew from nature with ſome ability. He alſo painted miniatures with ſucceſs. His own portrait may be ſeen in the character of an angel, in Hogarth's humorous print of "Paul before Felix." He died of a conſumption in the year 1750.

About this time John Pine, whoſe portrait Hogarth painted in the manner of Rembrandt, was in good repute, but the years of his birth and death are uncertain. His chief works are, "the Ceremonies uſed at the revival of the order of the Bath;" "The Deſtruction of the Spaniſh Armada," from the tapeſtry of the houſe of lords; a ſplendid edition of Horace, illuſtrated with copies of antique bas reliefs, gems, coins, &c. and a print of the houſe of commons.

The paſtorals and Georgics of Virgil were publiſhed by his ſon after his death, adorned in the ſame manner as the Horace, but printed with letter-preſs types.

Now alſo flouriſhed Arthur Pond, another native of England. He etched ſeveral portraits with freedom, taſte, and ſpirit, among which are thoſe of Mr. Pope (an excellent likeneſs), lord Bolingbroke, Dr. Mead, and himſelf. He was concerned with the Meſſrs. Knapton in publiſhing the volume of portraits of illuſtrious men which were engraven by Houbraken, Vertue, Gravelot, &c. and in promoting other meritorious works, particularly a ſet of plates from the great Italian maſters in imitation of chalk and biſtre drawings, which he accompliſhed with great ſucceſs. He alſo etched a ſet of caricatures from the chevalier Ghiſſi, and a few landſcapes, chiefly after Rembrandt.

Simon Francis Ravenet was another of Hogarth's occaſional coadjutors. He was a native of France, came into England about the year 1750, and ſettled in London. In the latter part of his life he reſided at Mother Red Cap's, near Kentiſh Town, where he died in 1774. He was of an amiable diſpoſition and much reſpected, and had the honour of inſtructing both Ryland and Hall in the art of engraving.

The ſhadows in his engravings are deep toned, and his ſtyle both of drawing and engraving vigorous, though ſomewhat mannered. Beſide what he produced after Hogarth, the following are eſteemed among his beſt prints: “The Prodigal Son,” (a large upright) from Sal. Roſa; “Lucretia deploring her Misfortune,” from A. Caſali; “The Manifeſtation of the Innocence of the Princeſs Gunhelda,” (its companion) from the ſame; “The Death of Seneca,” (a large plate) from Lucca Giordano; “The Arcadian Shepherds,” from N. Pouſſin; “The portrait of Lord Camden,” from ſir Joſhua Reynolds. He is alſo the author of a conſiderable number of vignettes, book plates, and ſmall portraits.

William Wynne Ryland was born in London in the year 1732. His genius for the fine arts manifeſted itſelf at an early period of his life, and he was accordingly placed under Ravenet. At the expiration of the term of his engagement he went to Paris, at that time the chief ſeminary of engraving, for improvement; and remained there five years.

Under the guidance of Boucher, who at that time led the faſhion in art, he applied with great aſſiduity to the ſtudy of drawing, but did not neglect to improve himſelf alſo in the practical part of engraving. From the deſigns of this principal miſleader of the taſte of France, Ryland engraved ſeveral plates, of which the principal and probably the beſt engraving he ever performed, is rather a large work, of which the ſubject is “Jupiter and Leda.”

He has here diſplayed great power as an engraver in lines. The print has a fine tranſparent tone; he has tempered the flimſy touchineſs of the French taſte with a portion of Ravenet's ſolidity; the ſoft firmneſs of fleſh is ably characterized in the figure of Leda, and the delicacy of the ſwan, and various textures of the ſurrounding objects, are rendered with much feeling and judicious ſubſerviency to the principal parts.

In one of his amatory poems, M'Kenzie emphatically exclaims, “Alas! are there faſhions in love!”—Alas! there are alſo faſhions in fine art. Unmeaning glitter, unprecedented ſoftneſs, unprincipled novelty, ſhall ſometimes ſet aſide for a while the truth and ſimplicity of nature, and the approbation of ages.

It was not, however, the falſe taſte of Boucher that turned aſide Ryland's talents from the mark at which he was evidently and ſucceſsfully aiming, when he produced his “Jupiter and Leda,” but a faſhion of ſtippling which he learned in France, and introduced, with his own modifications, into England. Stippling with the graver had been occaſionally practiſed both by Martin Schoen and Albert Durer in the very infancy of the art: the latter employed it in imitating the ſoft texture of beaver hats, as well as on ſome other occaſions. Perceiving that it was peculiarly expreſſive of ſoftneſs, Agoſtino Veneziano and Boulanger ſometimes ſtippled their fleſh, and Julio Campagnola his back grounds alſo. Almoſt a century afterward it was obſerved by De Marteau, who was now living, that by etching ſome of the dots of which this kind of engraving conſiſts, and engraving others, very ſucceſsful imitations of drawings hatched with chalk, might be produced. But Ryland employed ſtippling, ſo as rather to imitate ſuch drawings as are ſtumped than ſuch as are hatched with chalk, by which means he ſoftened down all energy of ſtyle, and has left poſterity to regret the voluntary emaſculation of the powers he had manifeſted in the engraving, which is the ſubject of the above comments.

Soon after his return to England, he, however, engraved in lines a portrait of the queen, after Coates, and that portrait of his majeſty, after Allen Ramſay, which Strange, from a miſunderſtanding either with the earl of Bute or Ramſay, had declined, but they poſſeſs neither the vigour nor taſte of his “Jupiter and Leda.” From this time he was appointed engraver to the king, and received an annual ſalary.

His ſubſequent engravings, in the chalk manner, are chiefly after Angelica Kauffman, and conſiſt of four half-ſheet circles, of which the ſubjects are, “Juno obtaining the Ceſtus of Venus,” “A Sacrifice to Pan,” “Cupid bound,” and “Cupid aſleep;” “Queen Eleanor ſucking the poiſon from the wounded Edward I.;” (an excellent engraving of the kind;) “Lady Elizabeth Grey ſoliciting the reſtoration of her Lands;” “Maria;” from Sterne's Sentimental Journey, and “Patience,” both upright ovals; alſo “King John ratifying Magna Charta.” The laſt plate being left, by Ryland's unfortunate death, in an unfiniſhed ſtate, has ſince been completed by Bartolozzi. This artiſt alſo engraved in lines, “Antiochus and Stratonice,” from Pietro de Cortona, and “The firſt Interview between Edgar and Elfrida,” from Angelica Kauffman, both large plates.

Ryland's engravings in the novel manner were, for the moſt part, printed in red, and this manner of engraving ſoon obtained the name of “the red chalk manner,” and was run after with avidity by the public. With ſo much heedleſs anxiety was it purſued, that people never ſtopt to conſider whether even red-chalk or ſtumped drawings themſelves, of which theſe prints were profeſſed imitations, were ſo good repreſentations of nature, or afforded a means ſo happy and efficient of transfuſing the ſoul of painting, as the art which previouſly exiſted, of engraving in lines, and which was then exerciſed in high perfection by Bartolozzi, Strange, Vivares, and Woollet: it was enough that it was new and red; Ryland and novelty led the way, and faſhion and the printſellers followed.

The print-dealers, upon miſtaken notions of private advantage, are ever exhauſting the permanent hopes of the art. Like ſavages, who are reckleſs of the future, they cut down the tree in order to obtain its fruit. The novelty of chalk engraving, by calling forth their ignorant exertions, coincided with, and encreaſed, the mania of the public, and except for the landſcapes of Vivares, Rooker, and Woollett, which required and exhibited more vigour and more detail of drawing than ſtippling could beſtow; and that now and then an hiſtorical engraving by Strange and Bartolozzi, and the ſeries from Weſt's hiſtory of England, (of which the death of general Wolfe was the firſt,) atteſted the exiſtence and maintained the dignity of the legitimate art, the engravers of Great Britain were compelled to feel, and ſilently to acknowledge, that

"Since ignorance was bliſs,
'Twas folly to be wiſe."

This mode of engraving, however, has ſince been greatly improved, and this improvement has been effected chiefly by living profeſſors. For an account of its proceſs and ſuſceptibilities, ſee the article Stippling.

Engraving, a mode or ſpecies of ſculpture performed by inciſion. The radix of the word ſhould rather be ſought in the Hebrew, than in the Greek language, becauſe the art itſelf was practiſed by the Hebrews and their Chaldean anceſtors for centuries before Greece had exiſtence.

There are ſeveral words uſed by the ſacred hiſtorian to expreſs or denote the work of the engraver. In the 28th chapter of Exodus, verſe 9, פתח ſignifies to make an opening, or inciſion; and hence come both the noun and its plural, פתוחים engravings.

One of the original ſenſes of the root is *to plough up*, ſo that the engraver is called *the plougher*; and frequently the word אבן, *a ſtone*, is added for the ſake of diſtinction, and both together may be properly tranſlated *the plougher* or *engraver in ſtone*.

Mr. Strutt with much truth obſerves, that "no word can expreſs more perfectly the operation of the engraver on metals of the preſent day (when performed ſimply with the graver) than the verb *to plough*." His line is a furrow, and in cutting it he turns up the copper, or other metal, as the huſbandman turns up the earth. The metal ſo turned up is termed the *burr*, which is afterwards removed with a tool termed by engravers a *ſcraper*.

In the 6th chapter of the firſt book of Kings, the word קלע is uſed to expreſs the hollowing out of the carved work upon the cherubim, palm trees, and open flowering in the ſanctuary, which were afterwards filled up with gold; which word in the Latin Vulgate is rendered *ſculpſit*; by others *cælavit*, and by others *incidit*.

Engraving has been performed in different countries and at different periods of time, on various ſubſtances; chiefly on metals, wood, and the oriental precious ſtones, which are called gems, but with inſtruments that have varied but little ſince they were firſt invented. For the latter arts, ſee Gem *Engraving* and Wood *Engraving*.

The metals upon which engraving is chiefly employed are copper and ſteel, the former for producing impreſſions on paper in various ways; the latter for ſtriking coins, medals, &c.

Engraving on copper, for the purpoſe of producing impreſſions, may be divided into five ſpecies, engraving in aqua-tinta, for which ſee Aqua-tinta; engraving in the chalk manner, for which ſee Stippling; engraving with aqua-fortis, for which ſee Etching; engraving on mezzotinto, for which ſee Mezzotinto *Engraving*, and the original art of engraving *in lines*.

Engraving in lines, for the purpoſe of producing impreſſions on paper, may almoſt be ſaid to be an art of modern invention, for though the ancients ornamented their pateras, armour, metal vaſes, &c. by this means, they appear never to have thought of printing from the inciſions, or lines cut with the graver; nor was it thought of at all until about the middle of the 15th century, for which ſee our accounts of the German and Italian *Schools of Engraving*.

This art is chiefly employed in repreſenting hiſtorical ſubjects, landſcapes, portraits, &c. &c. after pictures, or other deſigns made for the purpoſe.

It is performed, as we have ſtated, with the graver, dry point, or more frequently with the work of both theſe tools, mingled with lines corroded with aqua fortis. For the firſt there need but little apparatus, and few inſtruments. The plate you work on being well poliſhed, (for the method of preparing which, ſee Copper-*plates*,) is covered over with a thin ſkin of virgin-wax, and on this the outline of the draught, or deſign, done in black lead, red chalk, or other ungummed matter, is laid; and rubbed down for the wax to take off. The deſign, thus transferred upon the wax, is traced through on the copper, with a point, or needle; then heating the plate, and taking off the wax, the ſtrokes remain; to be followed, heightened, &c. according to the tenor of the deſign, with the graver, which is to be very ſharp, and well tempered.

The dry point, or needle, which has been of late much uſed in engraving, is a tool like an etching point, which being drawn hard on the copper, cuts a ſtroke, and raiſes a burr; the burr is ſcraped off, and there remains a ſtroke more ſoft and delicate than can be produced in any other way. See Dry *Point*.

In the adroit conduct of the graver and dry point the art chiefly conſiſts; for which there are no rules to be given; all depending on the habitude, diſpoſition, and genius, of the artiſt. However, ſome general obſervations and directions may not be improper. As the principles of engraving are the ſame with thoſe of painting, a perſon cannot expect to attain any conſiderable degree of perfection in this art who is not a good maſter of deſign; and therefore he ought to be well acquainted both with perſpective and architecture: for the former, by the proper degradations of ſtrong and faint tints, will enable him to throw backward, or bring forward, the figures and other objects of the picture or deſign which he propoſes to imitate; and the latter will teach him to preſerve the due proportion of its ſeveral orders, which the painter often entruſts to the diſcretion of the engraver. In order to preſerve equality and union in his works, the engraver ſhould always ſketch out the principal objects of his piece before he undertakes to finiſh them. Care ſhould be taken that the graver be carried level upon the plate, and be preſſed, as occaſion requires, with greater or leſs force, carrying the hand as evenly as poſſible. In engraving ſtraight lines, a leſs degree of preſſure ſerves for thoſe that are finer, and a greater is required to form the broader and deeper lines. In forming circular or curved lines, the hand and graver muſt be held ſteady, and the plate is to be moved upon the cuſhion under the graver. In large works a cuſhion is uſeleſs. The engraved work may be rendered more viſible, by rubbing it over with a roll of felt, dipt in oil, and which is called an oil rubber. The ſtrokes of the graver ſhould never be croſſed too much in the lozenge manner, particularly in the repreſentation of fleſh, becauſe ſharp angles produce the unpleaſing effect of lattice-work, and take from the eye the repoſe which is agreeable to it in all kinds of pictureſque deſigns: we ſhould except the caſe of clouds, tempeſts, waves of the ſea, the ſkins of hairy animals, or the leaves of trees, where this method of croſſing may be admitted. But in avoiding the lozenge, it is not proper to get entirely into the ſquare, which would give too much of the hardneſs of ſtone. In conducting the ſtrokes, the action of the figures, and of all their parts, ſhould be conſidered; and it ſhould be obſerved how they advance towards, or recede from, the eye; and the graver ſhould be guided according to the riſings or cavities of the muſcles or folds, making the ſtrokes wider and fainter in the light, and cloſer and firmer in the ſhades. Thus the figures will not appear jagged; and the hand ſhould be lightened in ſuch a manner, that the outlines may be formed and terminated without being cut too hard: however, though the ſtrokes break off where the muſcle begins, yet they ought always to have a certain connection with each other, ſo that the firſt ſtroke may often ſerve by its return to make the ſecond, which will ſhew the freedom of the engraver.

In engraving the fleſh, the effect may be produced in the lighter parts, and middle tints, by long pecks of the gravers, rather than by light lines; or by round dots, or by dots a little lengthened by the graver, or, beſt of all, by a judicious mixture of theſe together.

In engraving the hair and the beard, the engraver ſhould begin his work by laying the principal grounds, and ſketching the chief ſhades in a careleſs manner, or with a few ſtrokes; and he may finiſh it at leiſure with finer and thinner ſtrokes to the extremities. When architecture is to be repreſented, except it be old and ruinous buildings, the work ought not to be made very black; becauſe, as edifices are commonly conſtructed either of ſtone or white marble, the colour, being reflected on all ſides, does not produce dark ſhades, as in other ſubſtances. Where ſculpture is to be repreſented, white points muſt not be put in the pupils of the eyes of figures, as in engravings after paintings; nor muſt the hair or beard be repreſented as in nature, which makes the locks appear flowing in the air; becauſe in ſculpture there can be no ſuch appearances.

In engraving cloths of different kinds, linen ſhould be done with finer and cloſer lines than other ſorts, and be executed with ſingle ſtrokes. Woollen cloth ſhould be engraved wide, in proportion to the coarſeneſs or fineneſs of the ſtuff; and when the ſtrokes are croſſed, the ſecond ſhould be ſmaller than the firſt, and the third than the ſecond. Shining ſtuffs, which are generally of ſilk or ſatin, and which produce flat and broken folds, ſhould be engraved more hard and more ſtraight than others, with one or two ſtrokes, as their colours are bright or otherwiſe; and between the firſt courſe of lines other ſmaller muſt be occaſionally introduced, which is called interlining. Velvet and pluſh are expreſſed in the ſame manner, and ſhould always be interlined. Metals, as armour, &c. are alſo repreſented by interlining, or by clear ſingle ſtrokes. In architecture, the ſtrokes which form the rounding objects ſhould tend to the point of ſight; and when whole columns occur, it is proper to produce the effect as much as poſſible, by perpendicular ſtrokes. If a croſs ſtroke is put, it ſhould be at right angles, and wider and thinner than the firſt ſtroke. The ſtrokes ought to be frequently diſcontinued and broken, for ſharp and craggy objects. Objects that are diſtant towards the horizon ſhould be kept very tender. Waters that are calm and ſtill are beſt repreſented by ſtrokes that are ſtraight, and parallel to the horizon, interlined with thoſe that are finer; omitting ſuch places as, in conſequence of gleams of light, exhibit the ſhining appearance of water; and the forms of objects, reflected from the water at a ſmall diſtance upon it, or on the banks of the water, are expreſſed by the ſame ſtrokes, retouched more ſtrongly, or faintly, as occaſion may require, and even by ſome that are perpendicular. For agitated waters, as the waves of the ſea, the firſt ſtrokes ſhould follow the figure of the waves, and may be interlined, and the croſs ſtrokes ought to be very lozenge. In caſcades, the ſtrokes ſhould follow the fall, and be interlined. In engraving clouds, the graver ſhould ſport, where they appear thick and agitated, in turning every way according to their form, and their agitation. If the clouds are dark, ſo that two ſtrokes are neceſſary, they ſhould be croſſed more lozenge than the figures, and the ſecond ſtrokes ſhould be rather wider than the firſt. The flat clouds, that are loſt inſenſibly in the clear ſky, ſhould be made by ſtrokes parallel to the horizon, and a little waving; if ſecond ſtrokes are required, they ſhould be more or leſs lozenge; and when they are brought to the extremity, the hand ſhould be ſo lightened, that they may form no outline. The flat and clear ſky is repreſented by parallel and ſtraight ſtrokes, without the leaſt turning. In landſcapes, the trees, rocks, earth, and herbage, ſhould be etched as much as poſſible: nothing ſhould be left for the graver but perfecting, ſoftening, and ſtrengthening. The dry point produces an effect more delicate than the graver can, and may be uſed to great advantage in linen, ſkies, diſtances, ice, and often in water, eſpecially in ſmall engravings. In moſt things it is proper to etch the ſhadows, only leaving the lighter tints for the dry point, graver, &c.

The other inſtruments, beſides the graver and dry point, are, a cuſhion, or ſand-bag, to lay the plate on, to give it the neceſſary turns and motions: a burniſher, round at one end, and uſually flattiſh at the other, to rub out ſlips and failures, and to ſoften the ſtrokes, &c. A ſcraper, to pare off the ſurface, on occaſion, and remove the burr; and a rubber of black cloth, or hat, to fill up the ſtrokes, that it may ſhew how the work proceeds: but the latter ſhould be ſparingly uſed.

ENGRAVING *on ſteel*, is chiefly employed in cutting punches, matrices, and dies, proper for ſtriking coins, medals, and counters.

The method of engraving, with the inſtruments, &c. are the ſame for coins as for medals and counters: all the difference conſiſts in their greater, or leſs relievo; the relievo of coins being much leſs conſiderable than that of medals; and that of counters ſtill leſs than that of coins. The engraver in ſteel uſually begins with punches, or punchions, which are in relievo, and ſerve for making the creux, or cavities of the matrices, and dies; though ſometimes he begins immediately with the creux; but it is only when the intended work is to be cut very ſhallow. The firſt thing is to deſign his figures; then he moulds them in white wax, of the ſize and depth required; and from this wax he graves his punch.

This punch is a piece of ſteel, or, at leaſt, of iron and ſteel mixed; on which, before they temper, or harden it, the intended figure, whether a head, or a reverſe, is cut, or carved, in relievo. The inſtruments uſed in this *graving* in relievo, which are much the ſame as thoſe wherewith the finiſhing of the work in creux is effected, are of ſteel: the principal are, gravers of divers kinds, chiſſels, flatters, &c. when the punch is finiſhed, they give it a very high temper, that it may the better bear the blows of the hammer, wherewith it is ſtruck, to give the impreſſion to the matrice.

What they call *matrice*, or *matrix*, is a piece of good ſteel, of a cubic form, called alſo the *dye*, whereon the relievo of the punch is ſtruck in creux: it is called *matrix*, becauſe in the cavities, or indentures, thereof, the coins, or medals, ſeem formed, or generated, as animals are in the matrix of their mother. To ſoften this ſteel, that it may more eaſily take the impreſſions of the punch, they make it red-hot; and, after ſtriking the punch thereon in this ſtate, they proceed to touch up, or finiſh, the ſtrokes and lines, where, becauſe of their fineneſs, or the too great relievo, they are in any reſpect defective, with ſome of the tools above-mentioned.

The figure thus finiſhed, they proceed to engrave the reſt of the medal; as the mouldings of the border, the engrailed ring, letters, &c. all which, particularly the letters, and graining, or engrailment, are performed with little ſteel punches, well tempered and very ſharp. Add, that as they ſometimes make uſe of puncheons to engrave the creux of the matrix, ſo, on ſome occaſions, they make uſe of the creux of the matrix to engrave the relievo of the punch.

To ſee and judge of the engraving in creux, divers means have been deviſed to take the impreſſions therefrom, as the work proceeds; ſometimes they make uſe of a compoſition of common wax, turpentine, and lamp-black; which, always retaining its ſoftneſs, eaſily takes the impreſſion of the part of the graving it is applied to; but this only ſerving to ſhew the work piece-meal, they have had recourſe to other ways to ſhew the whole figure. The firſt by pouring melted lead on a piece of paper, and clapping the matrice thereon; the ſecond, with melted ſulphur, managed the ſame way; and the third, proper only where the graving is ſhallow, by laying a piece of ſoft paper on the graving, and over the paper a leaf of lead; when giving two or three blows with a hammer on the lead, the paper takes the impreſſion of the work.

When the matrix is quite finiſhed, they temper it, rub it well with a pumice-ſtone, and clean out the ſtone again with a hair-bruſh; and, laſtly, poliſh it with oil and emery: in this condition it is fit for the mill, to be uſed to ſtrike coins, medals, &c.

After the like manner are the matrices for caſting of printing letters engraven. See *Letter* FOUNDERY.

ENGRAVING *of ſeals, ſtamps, puncheons, marking irons, gilding irons*, and other matters, for goldſmiths, pewterers, bookbinders, &c. either in relievo, or indenture, is performed after the manner laſt deſcribed.

ENGRAVING *in wood*. See CUTTING *in wood*, and WOOD *Engraving*.

ENGRAULIS, in *Ichthyology*, a name given, by ſome authors, to the anchovy, called alſo, by ſome, lycoſtomus, and, by others, halecula. See ENCRASICOLUS.

ENGROSSING, the writing a deed over fair and in proper legible characters. Among lawyers it more particularly means the copying of any writing fair upon parchment, or ſtamped paper. See COPY, CALLIGRAPHUS, &c.

ENGROSSING, in *Law*, denotes the getting into one's poſſeſſion, or buying up large quantities of corn, or other dead victuals, with intent to ſell them again. This muſt of courſe be injurious to the public, by putting it in the power of one or two rich men to raiſe the price of proviſions at their own diſcretion. And ſo the total engroſſing of any other commodity, with intent to ſell it at an unreaſonable price, is an offence indictable and fineable at the common law. (Cro. Car. 232.) And the general penalty for this offence, as well as for *foreſtalling* and *regrating* (which ſee), by the common law, (for all the ſtatutes concerning them were repealed by 12 Geo. III. c. 71.) is, as in other minute miſdemeſnors, diſcretionary fine and impriſonment. (1 Hawk. P. C. 235.) Among the Romans theſe offences, and other mal-practices to raiſe the price of proviſions, were puniſhed by a pecuniary mulct. "Pœna viginti aureorum ſtatuitur adverſus eum, qui contra annonam fecerit, ſocietatemve coierit quo annona carior fiat." (Inſ. 48. 22. 2.)

ENGSTLEN, in *Geography*, a remarkable ſpring of Switzerland, in the canton of Berne, in the valley called Gentel. The water flows only from the beginning of May till the latter end of Auguſt, and that twice a day towards eight o'clock in the morning, and towards four in the afternoon. This circumſtance is conſidered as miraculous: the inhabitants fancy that providence purpoſely ſends them this water in the ſeaſon, and at the time when they are to water their cattle. Nothing, however, is more eaſily explained than this phenomenon. Many brooks iſſue from mount Engſtlen, and form a ſmall lake. In the ſummer months, the ſnow water cauſes this lake to overflow; and the melting of the ſnow begins with the day, and ceaſes towards night. F. I. Durand's Statiſtique élémentaire de la Suiſſe, 1795.

ENGUELEGUINGIT, a town of Africa, in the empire of Morocco, not far from Mogador.

ENGUICHE, in *Heraldry*, is applied to the great mouth of a hunting horn, when it has a rim of a different colour from the horn itſelf.

ENGYSCOPE, from εγγυς, *near*, and σκοπεω, *I obſerve*, a machine better known under the name of microſcope. See MICROSCOPE.

ENGYTHECA, from εγγυς, *near*, and θηκη, *repoſitory*, in *Antiquity*, a cup-board, or place where cups and other veſſels uſed to be laid.

ENGYUM, or ENGUYUM, in *Ancient Geography*, a town of Sicily, ſituated near mount Maurus, at the ſprings of Alæſus. Cicero (in Verr.) repreſents it as one of the moſt conſiderable cities of that iſland. It was founded by the Cretans, and famous for a temple dedicated to Ceres, in which, it was conſtantly affirmed, certain goddeſſes, called the "Mothers," appeared from time to time. Plutarch ſays, that this temple was built by the Cretans, and dedicated to theſe goddeſſes ſo called, *viz.* Cybele, Juno, and Veſta. This writer adds, that in the temple were lodged javelins and brazen helmets, which had been conſecrated to the goddeſſes of the place by Meriones and Ulyſſes. The town was ſituated in the interior of the iſland, to the weſt of Hubita.

ENHADDAD, a town of Judea, compriſed in a part of the tribe of Iſſachar.

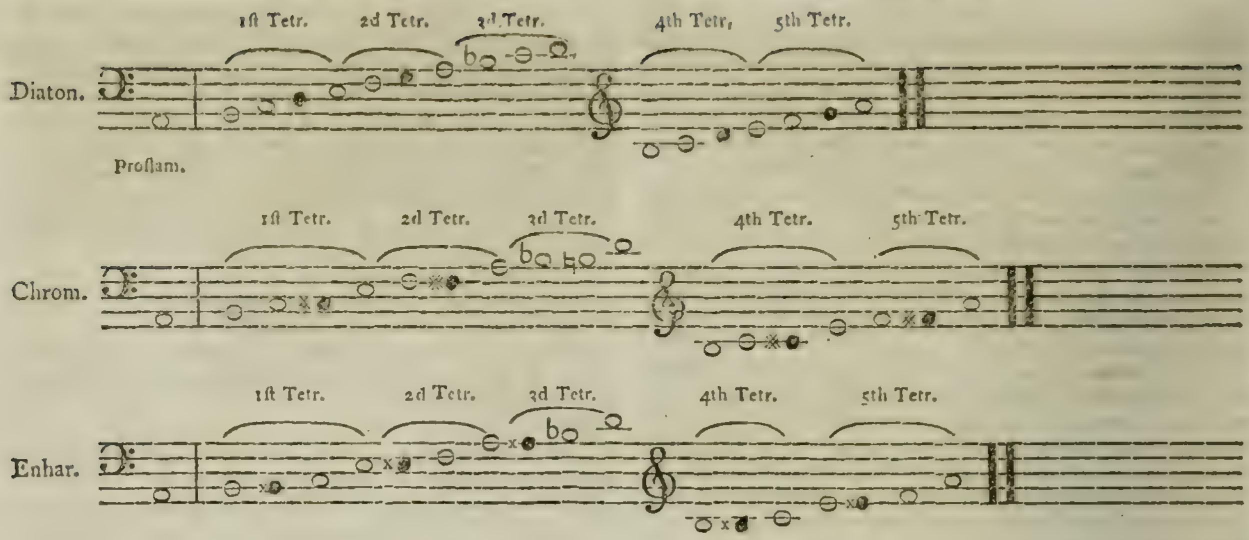
ENHALLOW, in *Geography*, one of the ſmaller Orkney iſlands, between Rowſa and Pomona.

ENHANCE, *To*, in *Law*, is to raiſe the price of goods or merchandize. See ENGROSSING and FORESTALLING.

ENHANCED, in *Heraldry*, a term applied to any ordinary, when removed from its uſual ſituation, and placed higher in the field.

ENHARMONIC GENUS, in the *Ancient Greek Muſic*. The Greeks included all muſical ſounds in three genera or kinds of interval: the diatonic, for tones and ſemi-tones; the chromatic, for ſemi-tones and minor thirds; the enharmonic, for quarter-tones and major thirds. The ſcale of each genus was arranged in tetrachords, or ſyſtems of four ſounds, of which the firſt and laſt were ſtantes, immobiles, or fixed; while the two middle ſounds were termed mobiles, or changeable: and it is by theſe changes that the genera are diſtinguiſhed.

Each of the three genera had ſome ſounds in its ſcale that were peculiar and characteriſtic, and ſome that were in common with the other two. For inſtance, B C E F A Bb and d, were uſed in all the three genera, whereas D G were peculiar to the diatonic, C♯ and F♯ to the chromatic, and B × E × and A × to the enharmonic. A complete ſcale of each genus in modern notes will explain this matter better than words.



This ſubject will be further purſued under the articles *Ancient Greek* Music, Genera, and Tetrachords.

As modern melody is built upon harmony, derived from the harmonics of a fundamental-baſe, we have no inſtruments with quarter-tones, or which can furniſh a baſe to an enharmonic melody, if we had the power of framing and executing it with the voice or violin. We have, therefore, only two genera in our muſic, with all our refinements in melody of nominal enharmonic ſharps, dieſes, double flats, and ſharps, &c.: which two genera, the diatonic, conſiſting of five tones and two ſemi-tones in the octave, ſuch as the key of C natural ſupplies upon keyed inſtruments; and the chromatic, conſiſting entirely of ſemi-tones, twelve in number, ſuch as moving from any given note to its octave by ſemi-tones will furniſh. See Tone, Semi-tone, and *Enharmonic* Sharps or Dieses.

Enharmonic *Dieſis*, is an interval whoſe ratio is $\frac{125}{128} = 21\Sigma + 2\mathrm{m}$. See *Enkarmonic* Diesis.

Enharmonic *Degree of Ariſtoxenus*, otherwiſe his dieſis quadrantalis, was a quarter of the major tone, or $26\Sigma + \frac{1}{2}\mathrm{f} + 2\frac{1}{4}\mathrm{m}$.

Enharmonic *Degree of Euclid*, otherwiſe his dieſis quadrantalis, was three-thirtieths of a minor fourth, or $25\frac{2}{7}\Sigma + \frac{1}{2}\mathrm{f} + 2\frac{1}{5}\mathrm{m}$.

Enharmonic *Ditone of Euclid*, was twenty-four thirtieths of a minor fourth, or $203\frac{1}{3}\Sigma + 4\mathrm{f} + 17\frac{3}{4}\mathrm{m}$.

Enharmonic *Quarter of a tone*, is the ſame with *enharmonic dieſis*, above.

ENHYDRI, in *Chemiſtry*, are ſmall nodules of chalcedony, each containing a drop of water, which are found in the porous trap of the picentine. They are often poliſhed and ſet in rings, rather as an object of curioſity than of much beauty; and after a time the water uſually diſappears by evaporation.

ENHYDRIA, in *Ancient Geography*, a town of Phœnicia, between Caranus and Marathus. Strabo.

ENHYDRIS, the ancient Greek name for the otter.

ENJEDIM, George, in *Biography*, a learned Unitarian divine, who flouriſhed in the 16th century, was a native of Hungary, whence he removed to Tranſylvania, where he became a ſuperintendant of the Unitarian churches. He died in the year 1597, and was regarded as one of the beſt writers in what is called the Socinian cauſe. His principal work was entitled "Explicatio Locorum Scripturæ Veteris et Novi Teſtamenti, ex quibus Dogma Trinitatis ſtabiliri ſolet," 4to. The firſt impreſſion of this work was burnt by the orthodox, but a new edition was afterwards publiſhed in the Netherlands. Moreri.

ENIF, in *Aſtronomy*, a fixed ſtar of the third magnitude, in Pegaſus's mouth.

ENIGMA. See Ænigma.

ENIMIE, Sainte, in *Geography*, a ſmall town of France, in the department of Lozere, 12 miles S.W. of Mende, in a country formerly known by the name of le Gévaudan.

ENINGIA, in *Ancient Geography*, a country or iſland in the north of Europe, in the Serius Codanus or Baltic ſea, according to Pliny; ſuppoſed by ſome to be Finland.

ENIPEUS, or Enipe, a river of Greece, in Triphylia, which ran W. of Heraclea. In the time of Strabo, it was called *Barnichius*.

ENIPPA, or Agonippa, a mountain of Greece, in Bœotia.

ENISEI and Eniseisk. See Yenisei and Yeniseisk.

ENISIPIA, an iſland of the Mediterranean ſea, near Egypt, called *Æneſyppa* by Ptolemy, and *Eneſipaſta* by Strabo.

ENISPA, a town of the Peloponneſus, in Arcadia, called *Eniſpæ* by Seneca the tragedian.

ENIX, in *Geography*, a town of Spain, in the province of Grenada; 8 miles W. of Almeria.

ENIXUM Sal, in *Chemiſtry*, is the ſulphat of potaſh remaining after the preparation of nitrous acid. It is pure, if only nitre and ſulphuric acid have been made uſe of: but as the manufacturers of aquafortis uſually employ green vitriol inſtead of ſulphuric acid, the reſidual ſalt is much mixed with colcothar or oxyd of iron; from which, however, it may be ſeparated by ſubſequent ſolution and cryſtallization.

ENKIANTHUS, in *Botany*, from εγκυος, *pregnant*, and ανθος, *a flower*, "becauſe," ſays Loureiro, "its flowers are pregnant with others." Loureir. Cochinch. 276. Claſs and order, *Decandria Monogynia*. Nat. Ord. ——.

Gen. Ch. *Common Cal.* of ſix roundiſh, concave, pointed, coloured leaves. *Common Cor.* of eight oblong, flat, ſpreading petals, containing five florets, on long reflexed ſtalks.

Perianth of five ſmall, permanent, acute, coloured leaves. *Cor. proper* of one petal, bell-ſhaped; tube wide; limb ſhort, in five rounded ſegments. *Stam.* Filaments ten, awl-ſhaped, tumid at the baſe, hairy, attached to the bottom of the corolla, and ſhorter than its limb; anthers ovate, incumbent. *Piſt.* Germen five-ſided, ſuperior; ſtyle thick, as long as the ſtamens; ſtigma ſimple, coloured, ſhining. *Peric.* Berry ovate-oblong, five-ſided, of five cells. *Seeds* numerous, oblong, ſmall. *Loureiro.*

Eſſ. Ch. Common Calyx to ſeveral flowers; proper one inferior, of five leaves. Corolla bell-ſhaped, five-cleft. Berry of five cells, with many ſeeds.

The ſpecies are two.

1. E. *quinqueflora.* "Calyx containing five flowers. Stem arboreous." Tſiau tſung hōa of the Chineſe. Cultivated at Canton. Its branches laden with red flowers, before the leaves expand, are kept for ſeveral days in china vaſes of water among the opulent Chineſe, and are very ornamental, though deſtitute of ſcent. The *tree* is of a middle ſize, with a ſmooth *bark*, and ſpreading *branches*. *Leaves* crowded, oblong, pointed, entire, ſmooth. *Flower* ſolitary, of a beautiful red, crowned with a white fringe, and containing five florets within.

2. E. *biflora.* "Calyx containing two flowers. Stem ſhrubby." Sāu lièo hōa of the Chineſe. Native of Canton. A *ſhrub* three feet high, with ſpreading *branches*. *Leaves* lanceolate-ovate, entire, hairy, ſmall, crowded, with ſhort footſtalks. *Flowers* ſcarlet, terminal, crowded, ſeſſile. *Common Calyx* of five coloured, ovate, concave, deciduous leaves. *Common Corolla* none. Florets two in each common calyx. *Perianth* ſmall, deeply five-cleft; its ſegments lanceolate, hairy, ſpreading. *Cor.* bell-ſhaped, ſpreading; tube with five furrows or plaits; limb in five deep, ovate, large ſegments. *Filaments* ten, thread-ſhaped, erect, unequal, rather ſhorter than the corolla, inſerted into the receptacle; anthers ovate, incumbent. *Germen* ovate, very hairy; ſtyle thread-ſhaped, longer than the corolla; ſtigma thickiſh, five-cleft, gaping. *Berry?* (not ſeen ripe), ovate, with five cells and many very ſmall roundiſh ſeeds.

The above is Loureiro's account of the genus in queſtion, concerning which we confeſs ourſelves unable to form any decided opinion. His deſcription of the ſecond ſpecies is a little at variance with the generic characters, and what he every where terms a common calyx and common corolla muſt of courſe be bracteas. Some particulars indicate a plant of the *Arbutus* or *Vaccinium* tribe, but others diſagree. Ornamental ſcarlet flowers, ſo well known at Canton, muſt long ago have been introduced to the acquaintance of European botaniſts. This is one of thoſe botanical enigmas with which the good father Loureiro's book abounds, in conſequence of his having ſtudied almoſt entirely without communication with other botaniſts. Hence he took the *Hydrangea* for a *Primula*, and made a new genus of *Argemone mexicana.* See ECHTRUS.

ENKIOPING, or ENDKIOPING, in *Geography*, a ſmall town of Sweden, ſituated on a river cloſe to an inlet of the lake Mæler, and conſiſting chiefly of wooden houſes painted red. It ſtands on a ridge of ground compoſed of ſand and gravel, which once formed the ſhore of the lake; 21 miles S.W. of Upſal.

ENKIRCH, a town of Germany, in the circle of the Upper Rhine, and county of Sponheim; 3 miles N. of Traarbach.

ENKUSEN, a town of the iſland of Borneo.

ENLARGE, in the *Manege*, is uſed for making a horſe go large, that is, making him embrace more ground than he before covered. This is done when a horſe works upon a round, or upon volts, and approaches too near the centre, ſo that it is deſired he ſhould gain more ground, or take a greater compaſs. To enlarge your horſe, you ſhould prick him with both heels, or aid him with the calves of your legs, and bear your hand outwards. If your horſe narrows, he is enlarged with pricking him with the inner heel, and ſuſtaining him with the outer leg, in order to preſs him forwards, and make his ſhoulders go. Upon ſuch occaſions the riding-maſters cry only large, large. See IN.

ENLARGER L'ESTATE, in *Law*. See RELEASE.

ENLARGING STATUTE. See STATUTE.

ENMANCHE', in *Heraldry*, is when a chief has two lines drawn from the middle of the upper edge, to the ſides, the depth of half the chief; the two lines including an obtuſe angle, whoſe vertex is the centre of the top of the chief.

The heralds conceive this, as bearing ſome reſemblance to ſleeves; whence the etymology of the word, from the French *manche*, ſleeve. It differs from chappe, where the lines come from the top to the bottom of the chief.

ENNA, in *Ancient Geography*, now *Caſtro Giovani*, a city of Sicily, ſituated on an eminence in the middle of the iſland, whence, according to Diodorus, it was called the "navel of Sicily." It was one of the ſtrongeſt places in the iſland, and remarkable for its beautiful plains, fruitful ſoil, and the numerous lakes and ſprings which watered its territory; and the waters of which were highly commended for their limpidity and ſalubriouſneſs. Diodorus informs us, that Ceres was born in this diſtrict; and that ſhe firſt taught the inhabitants of Enna the art of agriculture. He adds, that the rape of Proſerpine by Pluto happened near Enna, while the young goddeſs was gathering flowers in a neighbouring meadow. The Enneans ſhewed a large cavern, which, as they believed, opened of itſelf, to make the god a way to his infernal kingdom. Hence originated the worſhip which the Sicilians paid to theſe two divinities; the magnificent temple which Gelo erected to Ceres in this city; and the ſolemn feſtival, which the Syracuſians annually celebrated near the fountain Cyane, ſuppoſed to have ſprung up when the earth opened under Pluto's feet. The temple of Ceres was famous and reſorted to from all parts of Italy, Greece, and Aſia, and was deemed one of the richeſt in Italy.

ENNEACHORD, in *Ancient Muſic*, an inſtrument with nine ſtrings.

ENNEACRUNOS, q. d. *the nine fountains*, in *Ancient Geography*, a fountain of Greece in Attica, at the foot of mount Hymettus, the waters of which were conveyed through nine pipes or channels into the town, conſtructed by order of Piſiſtratus.

ENNEACTIS, in *Natural Hiſtory*, a name given by Linkius to a ſort of ſtar-fiſh, of the more branched or aſtrophyte kind, which has only nine rays, where they firſt part from the body, but theſe divide into a vaſt number of others afterwards.

ENNEADECATERIS, in *Chronology*, a cycle, or period, of nineteen ſolar years.

The word is formed of εννεα, *nine*; δεκα, *ten*; and ετος, *year*.

Such is the lunar cycle invented by Meton, at the end whereof the moon returns nearly to the ſame point from which it departed. Whence the Jews, Athenians, and other nations, who were diſpoſed to accommodate the lunar months to the ſolar years, made uſe of the enneadecateris; allowing to ſeven of the years thirteen months apiece, and to the reſt twelve. See CYCLE, and EMBOLISMIC.

ENNEADECATERIS, *the Jewiſh*, is properly a cycle of 19 lunar years, beginning from *molad tohu*, and returning again and again; whereof every 3d, 6th, 8th, 11th, 14th, 17th, and 19th, are emboliſmic, or of 383 days 21 hours apiece; the reſt common, or of 354 days 8 hours apiece. See YEAR.—Conſequently, the Jewiſh enneadecateris is 6939 days 18 hours.

ENNEAGON, in *Geometry*, a figure of nine angles, and nine ſides.

The word is formed of εννεα, *nine*; and γωνια, *angle*.

ENNEAGON, in *Fortification*, denotes a place with nine baſtions. See FORTIFIED *Place*.

ENNEAHEDRIA, derived from the Greek εννεα, *nine*, and ἑδρα, a *ſide*, in *Natural Hiſtory*, the name of a genus of ſpars.

The bodies of this genus are ſpars, compoſed of nine planes, in a trigonal column, terminated at each end by a trigonal pyramid. Of this genus there are four known ſpecies. Hill's Hiſt. of Foſſ. p. 208.

ENNEANDRIA, in *Botany*, from εννεα, *nine*, and ανηρ, *a man*, the ninth claſs of the ſexual or artificial ſyſtem of Linnæus, conſiſting of plants with nine ſeparate or diſtinct ſtamens in the ſame flower with the piſtil or piſtils. It contains three orders, *Monogynia*, of which the valuable genus *Laurus*, including the Cinnamon, Caſſia, one ſort of Camphor, Sweet Bay, &c. is an example, and there are ſome other fine plants in this order; *Trigynia*, of which *Rheum* or Rhubarb, nearly allied to *Rumex*, is the only inſtance, and *Hexagynia*, conſiſting of *Butumus umbellatus* alone. Hence it appears that nine is an unuſual number in the parts of flowers, though not quite ſo uncommon as ſeven.

ENNEAPYRGÆ, in *Ancient Geography*, a town of Greece, in Attica, 7 or 8 leagues from the promontory of Sunium.

ENNEATICAL DAYS are every ninth day of a ſickneſs; which, ſome imagine, naturally occaſion a great alteration, either for the better or worſe.

ENNEATICAL *Years* are every ninth year of a man's life. See CLIMACTERIC.

ENNEBACKA, in *Geography*, a town of Norway; 26 miles S.E. of Chriſtiania.

ENNEEMIMERIS is one kind of the cæſura of a Latin verſe, where, after the fourth foot, there is an odd ſyllable ending a word, which helps to make the next foot with the following word; as in this inſtance,

> "Ille latus niveum molli fultus hyacintho,"

where all the four kinds of the cæſura occur.

ENNEL-LOUGH, in *Geography*, a lake of the county of Weſtmeath, Ireland, near Mullengar.

ENNEOPHTHALMOS, from εννεα, *nine*, and οφθαλμος, *eye*, in *Zoology*, a name given by ſome to the lamprey.

ENNERIS, in the *Ancient Ship-Building*, a name given to thoſe galleys, or veſſels, which had nine tires of rowers. Theſe were of a very conſiderable ſize; though Meibom has found ſo convenient a method of placing the rowers that he has taken off very much from that immenſe height others ſuppoſed they had above the water. We read of the teſſaracontes, and other amazing veſſels of this fabric; and that of Philopater having forty rows of oars, and that of Ptolemy Philadelphus, thirty; and ſome others which are ſpoken of, twenty. It has been diſputed by many, whether ſuch large veſſels as theſe were ever actually built, or uſed; but Meibom gives great reaſon to believe that they really were, though he, at the ſame time, alleges againſt Salmaſius, and the more ſanguine admirers of the works of the ancients, that very few veſſels were built larger than theſe enneres, or nine tiered ones, and proves it from Livy and Plutarch, and from Polybius. We are apt to admire, in many caſes, what we ought alſo to imitate, but never attempt it. This is the caſe in theſe galleys; and Meibom, who has given the rules of this ancient naval architecture, is of opinion, that by imitating it at preſent, modern galleys and galleaſſes might be built much more conveniently both for ſtrength and celerity, and alſo at leſs expence, than they are at preſent. Meibom. de Trirem.

The modern form is indeed allowed to be better than theirs; but if in the ſtructure, the proportion of the long ſhips of the ancients were obſerved, they might be greatly improved: in the modern way of five men ſitting at one oar in the galleaſſes, much ſtrength is waſted to no purpoſe, becauſe they ſit too near to the fulcrum, or ſtay, whereas a ſmaller number of rowers, at a greater diſtance from the ſtay, would give more ſtrength, and throw the veſſel along much more ſwiftly, and would require leſs charge. Galleys of this ſort, thus managed at a ſmall expence, would be found of great uſe in the large rivers, and in the ſhallow ſeas, and therefore convenient for the Baltic, the Britannic, and the Mediterranean ſeas, and would be the moſt uſeful of all veſſels for tranſporting great numbers of forces.

ENNEZAT, in *Geography*, a ſmall town of France, in the department of the Puy de Dôme, chief place of a canton in the diſtrict of Riom, with a population of 2393 individuals. The canton contains 8 communes and 9168 inhabitants, on a territorial extent of 142½ kiliometres.

ENNIS, a poſt-town in the county of Clare, Ireland, of which it is the capital. It is large and populous, and has the advantage of a ſmall port at Clare, which is ſituated a few miles lower on the river Fergus; the tide bringing up large boats thence to Ennis. There are at this town the remains of one of the fineſt abbey-churches in Ireland, built in an elegant ſtyle of Gothic architecture. It is a borough town, and ſends one member to the united parliament. It is 112½ Iriſh miles S.W. by W. from Dublin, and 17 N. by W. from Limerick. W. long. 8° 54'. N. lat. 52° 49'.

ENNISCORTHY, a poſt-town of the county of Wexford, Ireland. It is ſituated on the river Slaney, which is navigable for ſmall ſloops to this town. Its ſituation is agreeable and pictureſque; and there are the remains of a conſiderable caſtle built by the firſt Engliſh ſettlers. It is the eſtate of the earl of Portſmouth. Enniſcorthy has a manufacture of coarſe woollen-cloth, and is a thriving town. Near it are lead mines, which are very productive. Vinegar-hill, near this town, was a ſtrong hold of the inſurgents in 1798; and the loyal inhabitants were great ſufferers at that eventful period. Enniſcorthy was repreſented in parliament before the union. It is 60 miles S. from Dublin, and near 12 N. from Wexford.

ENNISKILLEN, a poſt-town of the county of Fermanagh, Ireland, and the place where the aſſizes are held. It is built in an iſland, formed by the river which unites the two lakes, and is the ſingle paſs of communication between the parts of the county which theſe waters ſeparate. The ſtrength of its ſituation pointed it out as a military poſt; and when the adherents of James II. excited a juſt alarm throughout the country, numbers flocked to this place, where they bravely reſiſted a much ſuperior force, and even gained ſeveral important victories. Theſe valiant men were formed into a regiment, which rendered effectual ſervice to king William; and to this day the 27th regiment glories in the name of the *Enniſkilliners*. There is a ſchool here, founded by James I. on the plantation of Ulſter, the income of which, by the great riſe in the value of lands, has become very conſiderable. Enniſkillen returns one member to the imperial parliament. Diſtance from Dublin N.W. 79 miles.

ENNISTYMOND, or Innistymond, a ſmall poſt-town of the county of Clare, Ireland; ſituated 118 miles W. by S. from Dublin, and 13 W. from Ennis.

ENNIUS, Quintus, in *Biography*, an ancient poet, was born at Rudiæ, a city of Calabria, near Tarentum, about the year of Rome 514, B. C. 237, and flouriſhed about the cloſe of the firſt Punic war. According to Silius Italicus, he ſerved as a centurion in Sardinia, when that iſland was ſubdued by T. Manlius, and diſtinguiſhed himſelf by his valour. After the war he probably remained in Sardinia; for Cornelius Nepos informs us, that Cato, the cenſor, when prætor, brought back with him from his government of Sardinia, the poet Ennius, who muſt at this time have been in his 35th year. Another of his patrons was Scipio Africanus the elder, who made him his companion in moſt of his campaigns. This fact we learn from Claudian. He was alſo intimate with Scipio Naſica. The notice taken of him by theſe eminent perſons affords favourable teſtimony to his general character and manners; although Horace (Epiſt. xix. l. 1.) repreſents him as warming his heroic vein by liberal potations. The gout, with which he was afflicted, and his depreſſed circumſtances, were probably owing to his intemperance. Theſe evils, however, he bore with great equanimity; and his life was prolonged to the age of 70. He is ſaid to have been the father of epic or heroic poetry among the Latins, though the Greek was his mother-tongue. He was diſtinguiſhed by that ruſtic vigour, which is the uſual characteriſtic of genius in an unpoliſhed age. Thus Ovid repreſents him;

> "Ennius ingenio maximus, arte rudis."

Lucretius mentions his having firſt brought the muſe to Latium; and Virgil has tranſcribed into his works many whole or half lines from Ennius, thus teſtifying his eſteem of him. The events of Roman hiſtory formed the leading ſubjects of a large performance entitled "Annals," ſubſequently divided into eighteen books. On certain days he was accuſtomed to recite portions of this poem. He alſo compoſed tragedies, comedies, epigrams, and ſatires; and alſo ſome didactic works. By his life of Scipio Africanus, he engaged the affection of the Cornelian family, who manifeſted their gratitude to him even after his death, depoſiting his aſhes in the ſame tomb with thoſe of Scipio, and erecting a marble ſtatue to him near that of this great commander. The poet Nævius, who was his contemporary, after having made ſome campaigns in the firſt Punic war, wrote the hiſtory of that war in verſe, according to the taſte of thoſe times. Fragments only of the works of Ennius remain; theſe have been publiſhed ſeparately, Amſt. 4to. 1707, and alſo in Mattaire's Corpus Poetarum.

ENNODIUS, Magnus Felix, biſhop of Pavia in the ſixth century, was born of illuſtrious parents about the year 473. His education and maintenance devolved upon an aunt, by whoſe death, before he was ſixteen years of age, he was reduced to diſtreſſing circumſtances, but afterwards, by a fortunate marriage, he attained to a ſtate of affluence. Notwithſtanding this union, he had a ſtrong inclination for the eccleſiaſtical profeſſion, and obtained his wife's conſent to enter into holy orders, whilſt ſhe at the ſame time embraced a religious life. He was ordained a deacon by Epiphanius, biſhop of Pavia, with whom he lived in habits of the ſtricteſt intimacy and friendſhip. He had an early taſte for literature, which he cultivated in connection with his theological ſtudies, with ſo much ſucceſs as obtained for him the reputation of an excellent ſcholar. On the death of his friend Epiphanius, he was admitted among the deacons of the church of Rome, and for ſome ſervices done for the popes and church, he was promoted to the ſee of Pavia about the year 510, and appointed on the commiſſion for negociating a re-union between the eaſtern and the weſtern churches. The only reward for his ſervices in this reſpect, was drawing down upon his head the reſentment of the emperor Anaſtaſius, who, after much ill treatment, diſmiſſed him home in a ſhattered veſſel, with a ſtrict prohibition of never again landing at any port in Greece, by which his life was expoſed to the moſt imminent danger. He arrived ſafe in Italy, but died as he was on his journey to Pavia, in the 48th year of his age. His works are numerous, and have been frequently printed; they were publiſhed, with many uſeful explanatory notes, at Paris, in the year 1611. Moſheim Eccl. Hiſt. Moreri.

ENNUI, a French term which is ſometimes uſed to denote a kind of liſtleſſneſs or unaptneſs for mental exertion; or which may be more ſcientifically defined to mean the uneaſineſs that prevails during the abſence of mental impreſſions. The averſion from *ennui*, or the deſire of intellectual emotion, is deſcribed by Helvetius, in his work "On Mind," as a very powerful and general ſpring of conduct, and he aſcribes to this law of the mind, perhaps, a greater degree of influence than that which properly belongs to it, conformably to the avowed ſentiments of a writer, who maintains that "to judge is to feel," (juger c'eſt ſentir.")

ENO, in *Geography*, a town of European Turkey, in the province of Romania; the ſee of a Greek archbiſhop; 28 miles N.W. of Gallipoli.—Alſo, a river of America, in North Carolina, which unites with Little and Flat rivers in Orange county, and forms the Negus, about 17 miles below Hillſborough.

ENOCH, in *Biography*, the ſon of Jared and father of Methuſelah, was the ſeventh in lineal deſcent from Adam, and born in the year B. C. 3382. Eminently diſtinguiſhed by his piety and virtue in a corrupt age, he was tranſlated to heaven in the 365th year of his age, without undergoing the pains of diſſolution. An apocryphal book, entitled "The Book or Prophecies of Enoch," has been aſcribed to this celebrated antediluvian, and is cited, as ſome ſay, by Jude in his epiſtle, and more certainly by Irenæus, Clement of Alexandria, and other ancient fathers. But this book was probably forged in the ſecond century. The Mahometans mention Enoch under the appellation of Edriſs, or Idriſs, and record many fables concerning him, which it is needleſs to mention.

Enoch, in *Ancient Geography*, a city ſaid to have been built by Cain in the land of Nod, where he had his family ſettled, and called after the name of his ſon Enoch. (Gen. iv. 16, 17.) Moſes places it, according to our tranſlation, on the eaſt of Eden; and Ptolemy mentions a city called Anuchtha in Suſiana, or Chuſiſtan, a country lying eaſtward from Chaldæa, which the learned Huet ſuppoſes to have been the ſame with that built by Cain. But it ſeems very improbable, that the city of Enoch, built before the flood, ſhould either withſtand the deluge or retain its ancient name, after ſo great a change in the ſurface of the earth. Beſides, Suſiana being a very fertile and pleaſant country, it is not likely that Cain ſhould be baniſhed thither, but rather to ſome barren and deſolate land, remote from the place of his nativity, and ſeparated by mountains, or other natural impediments, from intercourſe with his relations. As there was another Enoch (ſee the preceding article) beſides the ſon of Cain, it is not improbable that the city Anuchtha mentioned by Ptolemy, might have taken its name from him, whoſe memory would be held in veneration, or from ſome other Enoch or Anoch, who might have lived after the flood. Grotius and Junius are of opinion, that the country into which Cain retired was the deſart of Arabia; but as this country lies on the weſt, and not on the eaſt of Eden, it is ſaid, that the words which we tranſlate "on the eaſt" of Eden ſignify no more than "before" or "over-againſt" Eden, according to the tranſlation of the Septuagint. According to this opinion; the land of Nod muſt have been Arabia Deſerta, or ſome part of it, and not Suſiana. Wells's Geog. vol. i.

ENODIS, Culmus, in *Botany*, a culm or ſtraw deſtitute of any knot, joint, or prominent tranſverſe interruption. See Culmus.

ENOLA, in *Geography*, a town of Naples, in the province of Lavora; 4 miles N. of Fundi.

ENOLMIS, Ενολμις, in *Antiquity*, a deſignation given to Apollo's prieſteſs at Delphi, becauſe ſhe ſat on the tripod which was called olmos, ολμος. Hence alſo Apollo is called Enolmos, Ενολμος. Pott. Archæol. Græc. lib. ii. cap. 9. tom. i. p. 275.

ENOMTEKIR, in *Geography*, a town of Swediſh Lapland; 150 miles N. of Tornea.

ENON, in *Ancient Geography*, a place of Judea, ſituated near Jordan in the half-tribe of Manaſſeh; which was the place in which John baptized, (John iii. 23.) becauſe there was abundance of water. This place was between Shalim and Jordan, about 8 miles from Scythopolis.

ENOPA, a town of the Peloponneſus, in Meſſenia, ſituated on an eminence at a ſmall diſtance N. of Cardamyla.

ENORAINE, in the *Manege*, a wither-wrung horſe, or one that is ſpoiled in the withers. The word is obſolete.

ENORCHIS, in *Natural Hiſtory*, the name given by many authors, to that ſpecies of ætites, or eagle-ſtone, in which the callimus, or internal nucleus, is not looſe, ſo as to rattle in it when ſhaken, but remains fixed to one ſide. The Germans call this *hodenſtein*. The outer cruſt is uſually of a whitiſh colour, and the internal nucleus is yellowiſh or browniſh, and it is uſually of the ſize of a pigeon's egg, and of the ſhape of the human teſticle; whence the name.

ENORMOUS, ſomething exceſſive, or monſtrous, eſpecially in bulk. The coloſſus of Rhodes was of an enormous ſtature.

The word is formed of the privative *e*, and *norma*, *rule*; q. d. *void of, or contrary to, rule or meaſure; contra normam.* In the corrupt ages of Latinity, they uſed *innormis*, and *inormis*.

In the French juriſprudence, *læſio enormis*, *enormous damage*, is that which exceeds half the value of the thing ſold.

ENOTAEVSK, in *Geography*, a town of Ruſſia, in the government of Caucaſus, on the Volga; 72 miles N.N.E. of Aſtrachan.

ENOUREA, in *Botany*, (a barbarous name, from the Caribæan word *Enourou*.) Aublet Guian. v. 1. 587. t. 235. Juſſ. 249. The only ſpecies is E. *capreolata*, a climbing ſhrub, with ſomething of the habit of a *Paullinia*, furniſhed with circularly-turned tendrils, pinnated leaves, ſpiked flowers, and a remarkable globular capſule of three valves, containing a globular ſeed imbedded in farinaceous pulp. Juſſieu has copied its characters from Aublet, but Schreber has paſſed it by.

ENQUEST, or Inquest, in *Law*, denotes an inquiſition of a jury by hearing of witneſſes.

This is the moſt uſual manner of trial, in all cauſes, both civil and criminal, within this realm. In civil cauſes, after proof is made, on either ſide, of ſo much as each party thinks good for himſelf; if the doubt be in the effect, it is referred to the diſcretion of twelve indifferent men, impanelled by the ſheriff for that purpoſe; and as they bring in their verdict, ſo judgment paſſeth: for the judge ſaith, *the jury findeth the fact thus.* See Writ *of Enquiry.* For the enqueſt in criminal cauſes, ſee Jury.

ENRICHED Column. See Column.

ENRICHING Plants, a term uſed, by the Engliſh farmers, to expreſs ſuch plants as are found to do good to land, rather than to exhauſt it, and in conſequence of which the ſame piece of land will produce a good crop of corn, though it would, without the aſſiſtance of their having been planted on it, have yielded a very poor one. The myſtery of this difference between plants, ſome of which are found to burn up, that is, impoveriſh lands, while others enrich it, and leave it fitter for ſucceeding crops than they found it, is explained by Mr. Tull. This author having obſerved, that breaking the earth, by digging, or horſe-hoeing, between the plants, gave them great increaſe, found that it was this practice that enriched the earth: and that, while corn and ſuch plants as ſtand cloſe, and cannot be hoed between, impoveriſh the ground, and ſuffer no means of enriching it again to be uſed, there were ſome other things, the crops of which being planted thinner, gave room to the earth to be ploughed, dug, or hoed between, and that theſe were the plants which were called the enriching kind by the farmers; and the whole ſecret lay in this, that the hoeing, ploughing, or otherways breaking the earth between them, in order to kill the weeds, enriched the ground greatly more, in proportion, than theſe plants exhauſted it; and the conſequence was, that though they had thriven very well, yet the earth was left richer than before, notwithſtanding all that they had imbibed from it. Tull's Horſehoeing Huſbandry, p. 37.

On this obſervation, this excellent author ſeems to have founded the ſyſtem of what he calls horſe-hoeing huſbandry, concerning which he has written a large and uſeful treatiſe. He found that this ſtirring up of the earth enriched it ſo greatly, that, where it was uſed in a proper manner, the kind of plant need not be changed, but that the ſame earth would yield a ſucceſſive ſeries of crops of the ſame plant, and that even without dunging, or ever lying fallow, and every crop, for a long time, would be better than the former ones. The method of ſowing, to this purpoſe, is not by ſcattering the corn with the hand, but ſowing it in rows, and leaving large intervals between, the naked earth of which might be turned up by the hoe. See Alley and Hoeing.

ENROL, in *Military Matters*, ſignifies the regiſtering of ſuch perſons as, being inliſted, or appointed, are placed upon the rolls, or ſtrength, of any particular regiment, troop, company, or portion of the military eſtabliſhment. The act of enrolment ſeems to be held neceſſary in proof of a ſoldier's having become a ſervant of the ſtate; equally ſo with the circumſtance of his having received pay, or ſome money, however trifling, in advance. For it does not appear reaſonable, that a ſoldier ſhould be puniſhed for abſenting himſelf from that employ in which he has not received either pay, or ſubſiſtence. It is not, however, to be underſtood, that, after being duly inliſted in the preſence of a magiſtrate, the recruit is at liberty to quit the party by whom he has been entertained: far otherwiſe; for though we hold a decided opinion regarding the devices often practiſed, to enſnare young men from their homes and families, we conſider it indiſpenſible that the ſacred engagement ſhould remain purely inviolate, after being once legally acknowledged by the party to be enrolled. See Inlist and Entertain.

In regiſtering, that is to ſay in enrolling, a recruit, it is uſual to be very exact in aſcertaining the place of his nativity, his religion or ſect, his age, his ſtate of health, eſpecially whether he be ſubject to fits, or be ruptured; while, for the purpoſe of apprehending him in caſe of deſertion, his height, complexion, general figure, the colour of his hair, and of his eyes, together with any particular diſtinguiſhing marks, whether natural or accidental, are all noted; compriſing, in the aggregate, what is called "deſcription roll," of which a tranſcript is ſent with each ſoldier, whenever draughted from one company or regiment to another.

Although a recruit is bound to the ſervice after being examined and deemed competent to ſerve, by the inſpecting ſurgeon, and the ſuperviſor of the recruiting ſervice of the diſtrict reſpectively, and after having acknowledged his being duly inliſted in preſence of a magiſtrate, by whom the oath of allegiance ſhould be tendered as ſpeedily as convenience might admit, he is not ſaid to be enrolled until he is efficiently placed upon ſome liſt, whether under the recruiting officers, or in any particular regiment, troop, or company. In ſome inſtances, eſpecially in the ſervice of the Eaſt India Company, the whole of the recruits are lodged at a general depot, under the charge of officers fixed thereat, but without being attached to any particular regiments until their arrival in India: in the mean while they are formed into ſquads, under the immediate controul of non-commiſſioned officers, by whom they are trained in the rudiments of military diſcipline. We cannot with ſtrict propriety ſay, that ſuch men are enrolled; nor, indeed, do we hold the term to be applicable until they are in a certain degree fixed in ſome particular company, and entered upon its muſter-roll, as well as upon the long-roll of the regiment.

ENROLLMENT. See Inrollment.

Clerk of the Enrollment *of fines*. See Clerk *of the Inrollments*.

ENS, in Latin *Aniſia*, *Anaſum*, or *Enſia*, in *Geography*, a town of Auſtria, in the province called Upper Auſtria, or the country above the Ens, in the diſtrict of Traun. It is ſituated on an eminence in the river Ens, which, not far from this place, falls into the Danube, 15 miles S. E. of Lintz, and 108 miles W. of Vienna. N. lat. 48° 11′. Its origin dates from the year 900, and it is built on the ſame ſpot where ſtood the Laureacum of the Romans, one of their colonies, which was deſtroyed by the Huns about the year 450. Ens is ſtrongly fortified; its citadel is called *Enſeek*, or the corner of Ens.

Ens, in Latin *Aniſus*, or *Anaſus*, a river of Germany, which has its ſource in the mountains of the former biſhopric, now grand duchy of Saltſburg, flows through Upper Auſtria, and falls into the Danube near the town of Ens.

Ens, *Entity*, *Being*, in *Metaphyſics*, is applied, in a general ſenſe, to every thing which the mind any way apprehends, and whereof it affirms, denies, proves, or diſproves, any thing. This other philoſophers call cogitable, and intelligible; and the logicians, thema.

Ens, in a leſs general ſenſe, ſignifies ſomething that is, or exiſts, ſome way farther than by being conceived, or being capable of being conceived, in the mind. This is particularly called ens poſitivum, or reale; poſitive, or real, being. In oppoſition to which ſtands non ens.

Ens, in its proper, or reſtrained ſenſe, is that to which there are real attributes belonging, or that which has a reality, not only out of the intellect, but in itſelf. This is what is properly meant by *res*, thing; and what we otherwiſe call ens reale, and alſo ſubſtance.

Ens *rationis*, is that which depends wholly on the mind, or which exiſts only in the imagination: of which they diſtinguiſh three kinds: ens rationis affectivum, which is done or produced by the mind, as knowledge; ens rationis ſubjectivum, which is received into the mind, as ſcience; and ens rationis objectivum, which is repreſented by the mind, as a chimera, a golden mountain, or the like. Which laſt, if it have no other manner of being, i. e. if it be preſented ſo as it does not, or cannot be, is what we moſt properly call ens rationis. The generality of ſchool philoſophers, and the Peripatetics among the reſt, aſſert, that there are of theſe entia rationis objectiva. Others deny there are, or can be, any ſuch things.

Ens, or Ens *primum*, in the *Ancient Chemiſtry*, denotes the moſt efficacious part of any natural mixed body, whether animal, vegetable, or foſſile, wherein all the qualities or virtues of the ingredients of the mixed are comprehended in a ſmall compaſs.

Paracelſus pretends to have been able to ſeparate the ens primum from bodies, and with it to effect prodigious things towards the renovation and reſtoration of youth; but his proceſſes are ſo obſcurely delivered, that no body has been induced to try them.

Ens *primum ſalium*, a name given by Paracelſus to a preparation of ſea ſalt, which he calls alſo a perpetual oil, and *ſal circulatum*, which ſee.

Ens *martis*, and *Ens veneris*. If the filings of iron or of copper be mixed with ſal ammoniac and ſtrongly heated, a decompoſition, greater or leſs in proportion to the quantity of metal employed, will take place: the ammonia will be liberated in the form of gas, while the muriatic acid will combine with the metal. The metallic muriat thus formed will ſublime at nearly the ſame heat as the undecompoſed reſidue of the ſalt, whence will reſult an accurate mixture of the two in the form of flowers, or a cruſt of a red colour: if iron filings have been uſed, and of a green colour if copper has been employed. The former of theſe is ens martis, the latter, ens veneris.

ENSATÆ, in *Botany*, from *enſis* a ſword, alluding to their ſword-ſhaped leaves, a name very happily applied by Mr. Gawler to the natural order of *Irides* of Juſſieu, it being deſirable that, if poſſible, every natural order ſhould have an expreſſive name, independent of any particular genus it may contain; or at leaſt that its name ſhould not be a mere unchanged repetition of that of any ſuch genus. This order is illuſtrated by the able botaniſt above-mentioned, in Sims and Konig's Annals of Botany, v. i. 219, and eſpecially in Curtis's Botanical Magazine.

ENSCONCED, in the *Military Art*. See Insconced.

ENSEELED, in *Falconry*, a term uſed for a hawk which has a thread drawn through her upper eyelids, and made faſt under her beak, to obſcure her ſight.

ENSEINT, in *Law*, a term uſed to denote a pregnant woman.

ENSEMBLE, a French term, ſometimes uſed in our language, literally ſignifying *together*, or *one with another*; being formed from the Latin, *in*, and *ſimul*.

In *Architecture*, we ſay, the enſemble, or tout enſemble of a building; meaning the work or compoſition, conſidered together, and not in parts; and ſometimes alſo the relative proportion of the parts to the whole. All thoſe pieces of building make a fine enſemble.

To judge well of a ſtatue, or other work of ſculpture, one muſt firſt examine whether the enſemble be good.

The tout enſemble of a painting, is that harmony which reſults from the diſtribution of the ſeveral objects of figures whereof the whole is compoſed. This picture is good, taking the parts ſeparately: but the tout enſemble is bad.

Ensemble, *Fr.* together. This adverb, uſed ſubſtantively, and received in the French muſical technica, is, according to Rouſſeau, inveſted with a very extenſive ſignification. To regard an object in its enſemble or totality, is to conſider the effect which the ſeveral parts produce, when united in a whole.

It is only in the execution of a piece of muſic, that this term is applicable, when the performers are ſo perfectly together in time and tune, ſeeming to be all ſo much animated by one ſoul, that they communicate exactly to the ear, all that the eye can ſee in the ſcore.

The being together does not merely depend on the accuracy with which each reads his part, but in the intelligence with which he feels its peculiar character and connection with the whole; whether in the exactitude of phraſeology, the preciſion of the movements, or ſeizing the inſtant and degree of pianos and fortes; or finally in the nice attention to ſuch ornaments, which the author has thought ſo neceſſary as to be indiſpenſible. It is in vain for muſicians to have abilities, they can never be together without an intelligence of the author's deſigns, and perfectly underſtanding each other: for it would be impoſſible to keep together a band of performers that are deaf, nor in the execution of muſic in a ſtyle with which they are totally unacquainted. It belongs to the maſters, conductors, and leaders of an orcheſtra, to guide, check, or accelerate individual performers, and to keep them together in the aggregate, which is always the office of a judicious firſt violin: who, by a certain firmneſs and energy in his manner, ſtrongly impreſſes the character of the piece in every ear. The vocal part is ſubordinate to the baſe and the time; the firſt violin ought to watch and follow the voice; the repienos ſhould liſten to and be guided by the firſt violin: and, finally, the harpſichord or piano forte, at an opera where the compoſer is ſuppoſed to ſit, ſhould be the principal and moſt important guide of the whole. In general, the more character there is in the ſtyle, periods, phraſes, melody, and harmony, the more eaſy it will be to ſeize the enſemble; becauſe the ſame idea, ſtrongly impreſſed on all minds, will preſide in the whole execution. On the contrary, when the muſic ſays nothing, and nothing is heard but a ſucceſſion of notes without meaning: then as there is no whole to which each performer can refer his part, the enſemble goes ill.

This (ſays M. Rouſſeau) was the reaſon why French performers could never be together.

ENSENE′, called alſo *Inſiné*, *Scheick Abadè*, and by the Arabs *Enſiné*, in *Geography*, a town of Egypt, ſituated towards the middle of the Said, eaſt of the Nile, and dependent on the province of Achmounain, which is on the other ſide. Abulfeda repreſents it as an ancient city, ſurrounded by a well cultivated country, abounding in fruits and harveſts. But theſe fertile plains have diſappeared with their inhabitants, and given place to ſands and deſerts. See Antinoe.

ENSHEMESH, i. e. *the fountain of the Sun*, a town or fountain, which lay on the frontiers of Judah and Benjamin. (Joſh. xv. 7.) The Arabians give this name to the ancient metropolis of Egypt, which the Hebrews called *On*, and the Greeks *Heliopolis*.

ENSIFORM, in *Anatomy*, a term equivalent to xiphoid, and meaning dagger-ſhaped. It is applied to the cartilage placed at the lower end of the ſternum. See Trunk.

Ensiform *Leaf*, in *Botany*, a vertical two-edged leaf like a ſword, as in many ſpecies of Iris. See Leaf.

Ensiform *Cartilage*. Dr. Hunter remarks, that, "if this cartilage be forced inwardly by a blow, it will occaſion vomiting and violent pains, by preſſing againſt the pylorus: in this caſe, it would be proper to lay it bare and elevate it." However, the ſame eminent writer admits, that as part of the diaphragm ariſes from the cartilage, the latter would be likely to be drawn out of its proper ſituation again by the action of ſo powerful a muſcle.

ENSIGN, in *Military Affairs*, is an officer whoſe duty it is to carry the colours; hence, when a youth firſt obtains a commiſſion in the infantry, he is ſaid to "receive a pair of colours." This is the firſt gradation above the rank of cadet, or volunteer, but is the loweſt of all the ranks in which commiſſions are held, and though obtainable by purchaſe, cannot be realized without ſatisfactory recommendations, and the approval of the commander of that regiment to which the nomination is to be made. From this, of courſe, ſome deviations are occaſionally admitted; but the neceſſity for aſcertaining that none but proper perſons be included within the circle of commiſſioned officers, occaſions conſiderable ſtrictneſs to be obſerved in this particular; notwithſtanding which, inſtances have occurred of men, by no means eligible to ſo honourable a diſtinction, having obtained commiſſions even in ſome of what are technically termed "crack regiments."

The duty of an enſign requires much attention, and at times ſome ſhare of bodily ſtrength; for, on a windy day, when the colours are fully diſplayed, a puny perſon might ſuffer conſiderable inconvenience; and, indeed, at all times, though ſupported in a ſling, the colours are rather oppreſſive; eſpecially to thoſe unaccuſtomed to carrying them. With regard to the ſtation of the enſign when acting with his company, or when bearing the colours, we refer to the head of Evolution; where the various changes of locality to which this officer is ſubject will be exhibited.

It is proper to remark, that although there are two ſtands of colours to each regiment, only one of them is properly called "the enſign." The flag, conſiſting of the union only, is called the king's colour, and always takes poſt of the other, which being in general of the ſame colour as the facings of the corps, and bearing any device or motto, by which it is diſtinguiſhed, is appropriately called "the regimental enſign."

In caſe of defeat, the enſigns bearing the colours muſt be very careful to collect as many of the fugitives as poſſible for the purpoſe of rallying the corps, or, at leaſt, of preventing it from being further diſgraced by the loſs of their facings, which formerly was an inſeparable conſequence annexed to the loſs of the colours. This regulation certainly muſt often produce conſiderable enthuſiaſm; and we may reaſonably conclude, that the attack made by a regiment under ſuch a privation, (which could only be remedied by its taking the colours of their opponents,) muſt be of the moſt arduous deſcription. In truth, we find in every walk of life, that where an imputation is to be removed, conſiderable energy is created by the exiſting diſgrace; and, that the moſt determined reſolution is formed not only to remove it, but to obtain a claim to pre-eminent conſideration in future.

The pay of an enſign in the Guards is five ſhillings and tenpence daily; in the line, only four ſhillings and eightpence: a ſum by no means adequate to the maintenance of a young gentleman in ſuch ſtyle as is at preſent too generally prevalent in almoſt every regiment. So far is this carried, that many young men of conſiderable merit are often compelled to exchange, or even to ſell out; becauſe their finances are inadequate to bearing a ſhare in the meſs expences. Nor is it unuſual for a notice to be given by the agent, or other perſon, to the candidate for a pair of colours, that ſuch a certain ſum annually will be needful, beyond his pay, to enable his keeping on a par with his brother officers. We are credibly informed, that in ſome regiments it is actually impoſſible for an officer to aſſociate with his peers, unleſs he may poſſeſs from 500 to 1000*l.* income, over and above his allowances!

When we analyſe this, we cannot but conſider it to be a national evil, and that too of no ſmall extent. We are far from wiſhing to ſee the reſpectability of our officers, in the ſmalleſt degree, tarniſhed; but it certainly cannot fail to ſtrike, even the moſt ſuperficial obſerver, that ſuch an exceſs of expence amounts nearly to a prohibition of the middling claſſes, and operates in the ſame manner, though not ſo avowedly, as the ancient regime of France, which proſcribed all but thoſe of noble family, or of eſtabliſhed deſcents through generations devoid of mercantile ſpeculation, from entering within the military pale. The very dreſs of ſome corps muſt coſt ſo much as to preclude the poſſibility of moderate fortunes being admitted. What ſhall we ſay to the charges made on a young gentleman's purſe, when it is ſtated, that in ſome regiments of horſe, full ſix hundred pounds may be required to equip him as a cornet! While an equal ſum per annum, will be *in requiſition* (here the term ſeems peculiarly appropriate) to enable him to eat, drink, and appear in the ſame company with his brother officers. Nor is this all; for the commiſſion may coſt a large ſum, ſuch as added to the other items would form a capital wherewith the youth might purchaſe an annuity, far exceeding the pay he would be likely to receive, for at leaſt ten or twelve years. We believe the Scotch regiments are no ſlouches in the field, and that they bear as many good characteriſtics as any in our ſervice; yet their dreſs is generally very plain, and their fare very far from ſumptuous. They are born economiſts; and from being brought up in a hardy, active routine, are capable of enduring great fatigue, and of putting up with various privations, which, to a perſon brought up with leſs ceremony, and habituated to the enjoyment of various luxuries, might be at leaſt unpleaſant, if not abſolutely diſtreſſing.

The Turkiſh enſigns are horſes' tails; the number of which diſtinguiſhes the rank of their commanders; the ſultan has ſeven, the grand vizier only three, &c. Thoſe of the Europeans are pieces of taffety, with divers figures, colours, arms, and devices, thereon. Xenophon tells us, that the enſign borne by the Perſians was a golden eagle on a white flag; the Corinthians bore the winged horſe, or Pegaſus; the Athenians, an owl; the Meſſenians, the Greek letter M; the Lacedæmonians, the A.

The Romans had a great diverſity of enſigns; the wolf, minotaur, horſe, boar, and at length the eagle. See Signa.

A military enſign, on a medal of a Roman colony, denotes it a colony peopled with old ſoldiers.

Ensign, in *Naval Affairs*, is the large flag hoiſted at the ſtern of a ſhip, whether of war or in the merchant ſervice, and denotes the country to which ſhe appertains, or the government under whoſe protection and authority ſhe is navigated. Of the ſeveral diſtinguiſhing enſigns, a more ample deſcription will be found under the head Flag: we ſhall briefly obſerve in this place, that this, as well as moſt of the colours of ſhips, whether *jacks* or *pennants*, are commonly conſtructed of bunting, and, that it is uſual to make them ſo ample as to occupy two-thirds of the flag-ſtaff in height, and to give them depth enough juſt to touch the ſurface of the water, when in a quieſcent ſtate. All enſigns are hoiſted with their unions, or diſtinguiſhing cantons, uppermoſt, next to the truck on the head of the flag-ſtaff: when hoiſted in the ſhrowds with the union, or diſtinguiſhing canton, lowermoſt, ſo as to reverſe all the figures, decorations, or inſcriptions, it is indicative of diſtreſs. The liberality of ſome nations has been conſpicuous in forbearing from making prizes of veſſels ſo circumſtanced, provided their commanders have engaged to return to the neareſt port, without intermediately offering any violence to ſuch as they might meet, there to remain in ordinary until the concluſion of the war.

The diſplay of an enſign in preſence of a ſtrange ſail is generally conſidered a mark of civility during times of peace, and in times of war ſerves to diſtinguiſh between friends and foes. During the latter period, ſuch veſſels as do not hoiſt their enſigns may be reaſonably ſuſpected to be privateers, or to be deſirous of evading every kind of communication. So long as the enſign remains hoiſted, during an engagement, the ſhip is to be conſidered in a ſtate of defiance; but when it is lowered, ſhe is ſaid to ſtrike; that is, to give up the conteſt, and to ſubmit, as a prize to her opponent. It occaſionally happens that a ſhip's enſign ſtaff, or the haulyards by which the enſign is hoiſted to the mizen-peak, is ſhot away; this does not indicate ſubmiſſion; on the contrary, the annals of warfare exhibit many inſtances of extraordinary courage in individuals, who, at ſuch moments, have ran aloft, or even ſtood on the poop, there to ſuſtain a portion of the enſign as a token of the moſt determined oppoſition. In the Britiſh ſervice we have three enſigns, namely, the white, the red, and the blue; the firſt is divided into equal portions, by a broad St. George's croſs of red, of which the upper canton, or quarter, is filled up with the union. The ſecond and third are both plain, with the exception of the union in the ſame canton. Theſe ſeveral enſigns indicate the rank of the admiral under which a ſhip of war is commiſſioned, or employed. Thus, an admiral of the white bears a white, or, as it is commonly called, a St. George's enſign, at the main top-gallant maſt head; a vice admiral of the white has one at the fore top-gallant maſt head; and a rear admiral one at the mizen top-gallant maſt head; the ſame rules of precedence obtain, with the admirals, vice-admirals, and rear-admirals of the red and blue reſpectively; each bearing a flag of his proper colour at that maſt head correſponding with his rank. When fleets are ſeparated into ſquadrons or diviſions, each ſhip aſſumes for the time the enſign of that admiral who commands the ſquadron, or diviſion, in which it acts. The ſame is obſerved by all veſſels acting under any particular port-admiral; all under his authority invariably bearing an enſign conformable to his deſignation, whether of the white, red, or blue.

ENSIGNCY, denotes the rank of that officer who bears the enſign or colours of a regiment of foot; and correſponds with that of "cornet" in the cavalry, and of "ſecond-lieutenant" in the artillery. It is, perhaps, one among the curious anomalies which pervade many parts of our ſyſtem, that an enſigncy ſhould exiſt in the engineer department, there being no colours to be carried in that corps, while the colours of the artillery battalions are borne by the ſecond lieutenants.

An enſigncy in a marching regiment may generally be obtained for about three hundred pounds, when ſerving within the realm: but in various ſituations abroad, eſpecially in the Eaſt Indies, where an increaſe of pay is given, the price is uſually much higher. See Ensign, *military*.

ENSISHEIM, in *Geography*, a handſome town of France, in the department of the Upper Rhine, in the diſtrict of Colmar, with a population of 1809 individuals. It is ſituated on the river Ill, 12 miles N. of Mulhauſen, 12 miles S.W. of Briſack, 294 miles S. by E. of Paris. N. lat. 47° 52′, and is the chief place of a canton, which has a territorial extent of 257½ kiliometres, 17 communes, and 10,122 inhabitants.

ENSTASIS, Ενστασις, of εν and ἵστημι, *ſtatuo*, in *Logic*, a manner of replying to an opponent, either by confuting his argument, or denying the juſtneſs of his concluſion. Voſſ. Rhet. lib. iii. p. 380.

Enstasis, in *Medicine*, a term uſed to expreſs the ingreſs of moleculæ into the vacuity of the pores which obſtruct them, and thereby cauſe diſeaſes. It is a word familiar with Eraſiſtratus and Aſclepiades, who was a follower of Democritus, and taught that moſt diſeaſes were cauſed by ſuch an ingreſs of matter into the pores. Thus Aſclepiades defined a phrenzy to be ſuch an enſtaſis in the membranes of the brain. Plutarch, in his precepts of Health, alſo mentions this enſtaſis: and Galen and Caſſius, who is ſuppoſed to have been of the ſect of the Rationaliſts, expreſſes the ſame ſenſe by the ſame word.

ENSTORF, in *Geography*, a town of Germany, in the circle of Bavaria and Upper Palatinate; 22 miles N. of Ratiſbon.

ENT, *Sir* George, in *Biography*, an eminent phyſician, was born at Sandwich, in the county of Kent, on the ſixth of November, 1604. After going through the uſual courſe of claſſical inſtruction, he was ſent to Sidney college, in Cambridge. He afterwards travelled to the foreign ſeats of learning, received the degree of doctor of phyſic at Padua, and on his return was incorporated in the univerſity of Oxford, on the ſeventh of November, 1638. During the uſurpation of Cromwell he ſettled in London, where he obtained conſiderable eminence in the practice of his profeſſion: he was elected a fellow, and afterwards preſident of the College of Phyſicians; and at length his merits were rewarded with the honour of knighthood by king Charles II. He enjoyed for a long period the eſteem and confidence of the public, and died at the age of eighty-five, on the 13th of October, 1689. He was buried in the church of St. Lawrence in the Jewry. He was a very intimate friend of the celebrated Dr. Harvey, and wrote a defence of his great diſcovery, entitled "Apologia pro circulatione ſanguinis contra Æmilium Pariſanum," which was publiſhed in 8vo. in the year 1641, and again in 4to. in 1685. About 1651 he prevailed with Dr. Harvey to conſent to the publication of his "Exercitationes de generatione animalium," which he ſuperintended, and preſented to the College of Phyſicians in a ſenſible and elegant dedication. He likewiſe publiſhed a treatiſe of his own in 1679, which was reprinted in 1682, entitled, "Animadverſiones in Malachiæ Thruſtoni, M. D. diatribam de reſpirationis uſu primario," in 8vo. His works were collected, and publiſhed in one volume 8vo. at Leyden in 1687, under the title of "Georgii Entii Opera omnia Medico-Phyſica, &c.:" and after his death, his "Obſervationes ponderis teſtudinis, cum in autumno terram ſubiret, cum ejuſdem ex terra verno tempore exeuntis pondere comparati, per plures annos repetitæ," were printed in the Philoſophical Tranſactions, N° 194, anno 1691. See Eloy Dict. Med. Biog. Dict.

ENTABLATURE, in *Architecture*, is that part of an order of column which is over the capital, comprehending the architrave, frize, and corniche.

The word ſeems formed of *tabulatum* or *intabulamentum*.

The entablature is alſo called the *trabeation*, and by Vitruvius and Vignola *ornament*. It is different in the different orders; indeed, it conſiſts of the three grand parts or diviſions above-mentioned, in all; but thoſe parts conſiſt of a greater or leſs number of particular members or ſubdiviſions, as the orders are more or leſs rich.

Vignola makes the entablature a quarter of the height of the whole column, in all the orders.

In the Tuſcan and Doric, the architrave, frize, and corniche, are all of the ſame height; in the Ionic, Corinthian, and Compoſite, the whole entablature being fifteen parts, five of them are allowed for the architrave, four for the frize, and ſix for the corniche. See Ionic, Corinthian, &c. and Column.

Entablature, or *Entablament*, is ſometimes alſo uſed for the laſt rows of ſtones on the top of the wall of a building, whereon the timber and covering reſt.

As this is frequently made to project beyond the naked of the wall to carry off the rain, ſome authors call it in Latin *ſtillicidium*, or *drip*. Such an entablature does not ſtand out far enough; it lets the water fall on the foot of the wall.

ENTABLER, in the *Manege*, is ſaid of a horſe whoſe croupe goes before his ſhoulders, in working upon volts; for, in the regular manege, one-half of the ſhoulders ought to go before the croupe. Thus we ſay, your horſe entables; for, in working to the right, he has an inclination to throw himſelf upon the right heel; which fault you may prevent, by taking hold of the right rein, keeping your right leg near, and removing your left leg as far as the horſe's ſhoulder. A horſe cannot commit this fault without committing that called aculer; but aculer may be without entabler.

ENTAIL, in *Law*, ſignifies fee tail, or fee entailed, that is, abridged, curtailed, or limited to certain conditions. For the docking of an entail, ſee Docking and Recovery. See Tail and Estate, &c.

ENTALIUM, the *pipe-ſhell*, in the *Materia Medica*, a ſhell of the ſame genus with the dentalia, being a ſpecies of the tubuli marini. It is frequent in the Eaſt Indies, and ſometimes is found on our own ſhores. The virtues aſcribed to it are the ſame with thoſe of the dentalium; but neither of them have any title to more than thoſe of alkaline abſorbents, like the other teſtaceous powders.

ENTE', in *Heraldry*, literally implies *engrafted*, and is uſed by foreign heralds to expreſs a method of marſhalling, little known among us; yet we have an inſtance of it in the fourth grand quarter of his majeſty's royal enſign, whoſe blazon is Brunſwick and Lunenburgh, impaled with ancient Saxony, *enté in pointe*.

ENTELECHIA, Εντελεχεια, of εντελεχης, *perfect*, a Greek term, by which Ariſtotle defines the ſoul; and which, not occurring in any other author, has given the critics and philoſophers infinite perplexity to diſcover its true meaning. See Soul.

Hermolaus Barbarus is even ſaid to have conſulted the devil about it; after which, in his paraphraſe on Themeſtius, whether from the devil or himſelf, we know not, he renders it by *perfectihabia*, which is not a whit the clearer.

Cicero, whoſe interpretation ſhould be preferable to that of any modern, defines entelechia (Tuſc. Queſt. lib. i. cap. i.) to be, "a certain, continued, and perpetual motion;" whence it ſhould ſeem, that Ariſtotle took the ſoul for the mode of the body; a continuous motion being, doubtleſs, a mode of body.

The common Peripatetics hold entelechia to ſignify act, and under it ſuppoſe the form of the compound or animal to be underſtood.

Laſtly, others, and thoſe the lateſt Peripatetics, agree, that the act, or entelechia, whereby Ariſtotle meant to explain

plain the nature of the ſoul, is either ſome mode of the body, as motion, or it is nothing.

ENTENDEMENT, in *Law*. See Intendment.

ENTER, *To, a Hawk*, among *Sportſmen*, is uſed of a hawk when ſhe begins to kill.

Enter, *To, a Hound*. See Entrance *of Hounds*.

ENTERADENES, of εντερον, *inteſtine*, and αδην, *gland*, in *Anatomy*, a name by which many authors have called the inteſtinal glands.

ENTERENCHYTÆ, of εντερα, *the viſcera*, and εγχυω, *I infuſe*, in *Medicine*, a name given by authors to the ſeveral inſtruments contrived for throwing clyſters into the bowels; ſuch as the bladder and pipe the ſyringe, and the like, for liquid clyſters; and the box with the double pipe for conveying the ſmoke of tobacco. See Clyster, and Fumigator.

ENTERFERING, in the *Manege*. See Cutting.

ENTERITIS, in *Medicine*, from ἔντερον, *inteſtine*, ſignifies an inflammation of the inteſtines. The diſeaſe has been variouſly denominated *ileus*, εἰλεος, *iliac paſſion*, *chordapſus*, &c.

The ſymptoms of inflammation of the bowels generally come on ſuddenly. An acute and fixed pain, with a ſenſe of heat in the abdomen, more eſpecially about the umbilicus or navel, often with a feeling of twiſting in that part, attacks the patient; this pain is increaſed by preſſure. Previouſly to its occurrence, or together with it, the uſual ſymptoms of fever come on, ſuch as rigor or ſhivering, followed by fluſhes of heat, thirſt, and dryneſs of the tongue; the pulſe becomes frequent, hard, and commonly ſmall; conſiderable anxiety enſues; the bowels are obſtinately coſtive; the ſtomach is ſoon deranged; and eructations, nauſea, and vomiting ſucceed. As the diſorder advances, the pain becomes more acute, without any diſpoſition to evacuation; the abdomen becomes diſtended with flatulence, and more tender under preſſure; and the urine is often voided with difficulty and pain. If the inflammation be not alleviated, gangrene generally enſues, often within twenty-four hours from the commencement of the diſeaſe, and terminates the life of the patient.

The occurrence of gangrene is indicated by a ſudden remiſſion of the pain, while, at the ſame time, the ſtrength fails, the pulſe ſinks, the voice grows feeble, the countenance ſhrinks, and aſſumes even a cadaverous aſpect, yet the diſtenſion of the belly is not diminiſhed, but often increaſed. This tendency to terminate ſpeedily in mortification conſtitutes the great danger of inflammation of the inteſtines. Sometimes the diſeaſe terminates in ſuppuration, which, though leſs rapidly fatal, moſt commonly wears out the patient's ſtrength and life in a lingering manner; but occaſionally this condition ends in recovery. The formation of pus is indicated in this diſeaſe, as in other internal inflammations, by the remiſſion, but not total ceſſation of the pain, and by the occurrence of frequent fits of rigor, and ſometimes by a purulent diſcharge by ſtool. But the diſeaſe, eſpecially when the aid of medicine is early and actively obtained, frequently terminates favourably, by reſolution, as it is called; *i. e.* by a gradual diminution and ceſſation of the ſymptoms. If the pains abate gradually, and the tenderneſs and diſtenſion of the abdomen leſſen, while the pulſe becomes ſofter and fuller, natural evacuations of fæculent matters are paſſed, and a free general perſpiration breaks out, this favourable termination may be anticipated. Whereas, the continuance of the conſtipation, and of the fixed pain, the increaſe of the ſickneſs and vomiting, the occurrence of the ſymptoms juſt deſcribed as indicative of gangrene, eſpecially if accompanied with hiccup and cold ſweats, are among the unfavourable prognoſtics.

The principal ſource of miſtake, into which the practitioner is likely to fall in treating this diſeaſe, is in confounding it with *colic*; a ſpaſmodic diſorder, which requires a treatment eſſentially different, but which, nevertheleſs, occaſionally terminates in enteritis. The diagnoſtic ſymptoms of the two complaints have been already ſtated at length, under the former article. See Colica.

Enteritis occurs moſt commonly in perſons ſomewhat advanced in life, generally after the age of forty, or fifty; and it ſeems to be moſt frequent in plethoric habits, and in thoſe particularly who indulge in indolence and full living. In ſome individuals there appears to be a conſtitutional irritability of the inteſtines, which renders them liable to attacks of inflammation, upon the application of ſlight cauſes.

The *exciting cauſes* of enteritis are various; among the moſt common are obſtructions in the bowels, which neceſſarily retain the fæces, until theſe, by their quantity or quality, become extremely irritating, and excite inflammation. Theſe obſtructions to the paſſage of the ſtools through the inteſtinal canal are occaſioned by different circumſtances. A ſpaſmodic contraction of any part of the canal, as in colic, if it continue for any conſiderable time, is liable to induce inflammation: a ſtricture, occaſioned by a chronic thickening of the coats of the bowels, ſometimes brings it on: *intro-ſuſception*, or the inverted paſſage of one part of the gut into the adjoining part, produces a ſimilar effect; as well as the ſtrangulation of the inteſtine from *hernia*, or rupture: the formation of calculus in the inteſtinal canal, which, though a rare occurrence, ſometimes takes place, may alſo occaſion a ſimilar obſtruction, and conſequent inflammation. Enteritis is likewiſe excited by irritating ſubſtances conveyed into the inteſtines, which, by their bulk, ſhape, or indigeſtibility, or by their chemical or ſpecific acrimony, produce much excitement in the canals. Thus, the ſwallowing of hard kernels, ſeeds, or ſtones of fruit, of pieces of metal, &c. has often induced the diſeaſe; and the preſence of *ſcybala*, or hardened fæces, and of calculous concretions, operates partly by the immediate irritation which they occaſion. Thus alſo, ſtrong concentrated acids or alkalis, ſpirituous liquors, high ſeaſoned food in large quantities, draſtic purgatives, worms, &c. in the inteſtinal canal, have excited inflammation in it in different inſtances. Hence the diſeaſe has ſometimes been the immediate effect of repletion, or of a fit of intoxication: and even a mild cathartic, when the bowels were loaded with much hardened fæces, which the medicine was incapable of removing, has, in ſome rare caſes, produced inverted motion and *intus-ſuſception*, terminating in enteritis. A very common cauſe of inflammation in the bowels is the application of cold to the legs and feet, or to the abdomen itſelf, eſpecially if ſudden or long continued. The retroceſſion of gout, rheumatiſm, eryſipelas, or chronic eruptions, from the external parts, is ſometimes followed by ſymptoms of inteſtinal inflammation.

In the *cure* of enteritis, as in all other acute inflammatory diſeaſes, the leading object is to remove the inflammation, from which all the other ſymptoms of the diſeaſe originate. This, though apparently an identical propoſition, cannot be too ſtrongly inculcated, in the treatment of enteritis; becauſe the exceſſive conſtipation of the bowels, which, in common with the reſt of the ſymptoms, is in general merely an effect of the inflammatory condition of the bowels, in ſome part, is often attacked by the inattentive practitioner with active purgative medicines, as if it were the primary object, and the ſource of all the miſchief. The inflammation is to be ſubdued by blood-letting, from a large orifice, to an extent which muſt be various according to the conſtitution of the patient, and the violence of the ſymptoms. This depletion may be aided in its effects by the application of leeches, and afterwards of a bliſter to the abdomen; and by the ſtricteſt abſtinence from all ſtimulating and nutritious aliment. The blood-letting muſt be repeated in a ſhort time, if the ſymptoms do not abate, and the ſtrength of the patient is ſufficient to ſupport the evacuation; which can only be determined by the obſervation and experience of the practitioner. If the pulſe ſhould become fuller and leſs wiry after the operation, it will afford a ſtrong reaſon for the repetition of it, ſhould the continuance of other ſymptoms appear to require it. The uſe of emollients externally was in great vogue among the ancients; and fomentations, or, what is better, the warm bath, may be reſorted to with advantage. Celſus recommends the uſe of warm cataplaſms, frequently changed, and covering the greater part of the trunk, "à mammis uſque ad inguina et ſpinam," and alſo a bath of warm oil;—"demittere totum hominem in calidum oleum." De Medicinâ, lib. iv. cap. 13. The dirty applications of living animals, or the ſkins of thoſe recently killed, can only operate as emollients, and are neceſſarily leſs effectual than fomentations; they are at preſent, therefore, fallen into diſuſe. Sydenham recommended the application of a live whelp to the abdomen in theſe caſes. Opera, ſect. i. cap. 4. p. 77. Edit. Lugd. 1726.

It muſt be obvious, that before the inflammation of the inteſtines is leſſened or removed by theſe meaſures, any additional irritation to the membranes, already in an acute ſtate of ſenſibility, whether by the immediate ſtimulus of a cathartic medicine, or by the contents of the bowels being forced forwards to the inflamed part, muſt tend to aggravate the diſorder, rather than to relieve it. In fact it is uſually found, that purgatives, given by the mouth, are not ſucceſsful, where this previous diminution of the inflammation has not been effected. And when this has been accompliſhed, ſome of the milder purgatives, as the neutral ſalts, ſhould firſt be adminiſtered, the action of the inteſtines downwards being at the ſame time ſolicited by emollient glyſters, which alſo contribute to the ſame relaxant purpoſes as the external fomentations. Dr. Gregory uſed to remark, in his lectures, that a purgative medicine had often been known to operate as ſoon as a bliſter, applied to the belly, began to riſe, which had not acted previouſly: and this obſervation is ſtill more commonly verified, after a free evacuation by blood-letting. See Edinburgh Med. and Surg. Journal, vol. i. p. 64. Some practitioners have attempted to open a paſſage for the fæces, by mechanically diſtending the large inteſtines, by throwing up five, ſix, or ſeven pints of warm water with an injecting ſyringe. This expedient may be uſeful in ſpaſmodic colic; but it is objectionable, in enteritis, on ſeveral grounds. Such diſtenſion can only be accompliſhed in the colon, or great gut; whereas the obſtruction by inflammation is commonly in ſome portion of the ſmall inteſtines, and therefore out of the reach of the enema. In the next place, any forcible diſtenſion of an inflamed and thickened canal, if it could be accompliſhed, would rather conduce to an increaſe of the inflammatory condition, than to leſſen it by the removal of fæces. In a word, all meaſures applied to the inflamed inteſtine ſhould be mild; ſince forcible ones cannot but augment the inflammation, upon which the impeded function of the organ depends. By way of glyſter, therefore, a little common ſalt, magneſia vitriolata, or infuſion of ſenna, with gruel or warm water, will probably anſwer every good purpoſe that can be expected from ſuch an expedient. Tobacco ſmoke has been often injected when milder means have failed, or infuſions of tobacco; but their ſucceſs, we believe, has not been often experienced. Indeed tobacco injections are liable to produce great ſickneſs and irritation, if that herb be not uſed in very ſmall quantities.

The extreme ſickneſs which often accompanies enteritis, and by which every thing that is taken into the ſtomach, whether liquid or ſolid, is rejected, renders it difficult, in ſome caſes, to produce any effect upon the bowels by internal medicine. In this caſe, the irritability of the ſtomach may be quieted by the ſaline effervеſcing draught, or by a ſmall opium pill, or, if this be rejected, by an opiate given in a glyſter; after which the neceſſary laxative medicines may be retained, and accompliſh the intended object. It ſhould be obſerved, however, that the ſtimulus of opium will prove rather injurious than uſeful, while the inflammation is unſubdued.

Where the inflammation has ariſen from ſtrangulated hernia, the operation, by which the ſtrangulation is removed, and the inteſtine returned into its place, can alone ſave the life of the patient. See Hernia.

We have already had occaſion to allude to a remedy for conſtipation of the bowels, which has been recommended as a laſt reſource, namely, a quantity of crude quickſilver; and to point out the abſurdity of the hypotheſes, which have led to its uſe, as well as ſome of the ill conſequences of it. Sydenham reprobates the practice, which appears to have been firſt adopted about his time. Loc. cit. p. 76. See Constipation.

When the inflammation of the inteſtines has been ſubdued, the utmoſt caution ſhould be employed, with a view to the prevention of a relapſe, to which the convaleſcent from enteritis is extremely liable. A thin, ſpare, and laxative diet, conſiſting of vegetable ſubſtances, of gruels, or barley water, or theſe mixed with milk, muſt be adhered to moſt rigidly for a conſiderable time after recovery; and all acrid, ſtimulating ſubſtances, or thoſe which are difficult of digeſtion, ſhould be moſt ſcrupulouſly avoided. The moſt fatal effects have been obſerved to take place, in ſome inſtances, from returning too ſoon to ordinary diet, after the removal of inflammation of the bowels. In order to guard againſt a future recurrence of the diſeaſe, the application of cold to the abdomen and feet ſhould be prevented by warm cloathing; and the occurrence of coſtiveneſs at all times avoided, by laxative diet or medicine, ſo that no accumulation of fæces can take place, and the ſteady action of the bowels be conſtantly preſerved.

ENTERMEW. See Falcon.

ENTEROCE'LE, (from εντερον, *an inteſtine*, and κηλη, *a tumour*, or *rupture*,) in *Surgery*; a hernia is ſo termed, when its contents are entirely compoſed of inteſtine.

ENTERODYNIA, from ἔντερον, *inteſtine*, and ὀδύνη, *pain*, in *Medicine*, a term uſed by ſome writers, as nearly ſynonymous with colic, but expreſſing a minor degree of pain; ſuch, for inſtance, as ariſes from the irritation of vitiated bile, loaded bowels, worms, &c. and which, therefore, laxative medicines generally relieve.

ENTERO-EPIPLOCE'LE, (from εντερον, *an inteſtine*, επιπλοον, the *omentum*, and κηλη, *a tumour*,) in *Surgery*, a term applied to a hernia, which contains both a portion of the bowels, and a piece of the omentum.

ENTERO-HYDROCE'LE, (from εντερον, *an inteſtine*, and ὑδροκηλη, *a dropſy of the ſcrotum*,) a ſcrotal hernia, containing a good deal of fluid.

ENTEROLOGY, from εντερον, *inteſtinum*, *a gut*, and λογος, *ſermo*, *diſcourſe*,) is properly a treatiſe of the bowels. Though the word is generally underſtood to include the contents of three cavities, head, breaſt, and all the viſcera or belly.

ENTERO'MPHALOS, (from εντερον, *an inteſtine,* and ομφαλος, the *navel,*) a hernia at the navel, and containing inteſtine.

ENTERORA'PHE, (from εντερον, *an inteſtine,* and ραφη, *a ſuture,*) a ſuture of the bowels.

ENTERO'SCHEOCELE, (from εντερον, *an inteſtine,* and οσχεοκηλη, *a rupture, or hernia ſituated in the ſcrotum,*) a ſcrotal hernia, the contents of which are entirely compoſed of inteſtine.

ENTERPEN, *To,* in *Falconry,* is a term applied to a hawk, when her feathers are wrapped up, ſnarled, or entangled.

ENTERPLEADER, in *Law.* See INTERPLEADER.

ENTERPRISE, denotes an undertaking attended with ſome difficulty and danger.

ENTERPRISE, in *Military Affairs,* appertains rather to thoſe deſultory expeditions which often prove of conſiderable importance in their conſequences; though, perhaps, apparently trivial, when compared with thoſe great events that ſometimes characterize a campaign. In ſome inſtances we ſee the moſt decided effects produced by the operations of enterpriſing partiſans, who, excluſive of the quantity of forage, and the intelligence they generally afford, diſtreſs the enemy ſeverely, by compelling him to act with ſuch circumſpection, and ſo to ſtrengthen his poſitions, as inevitably muſt weaken his other operations, as well as create conſiderable alarm among his troops, eſpecially when detached in expoſed ſituations.

In ſome countries, detached enterpriſes ſeem to conſtitute the chief incidents in warfare; thus, we find that irregular corps commanded by baron Trenck were peculiarly active, and haraſſed the enemy beyond meaſure! Thus, alſo, the Croats, the Pandours, and the Pindaries, of the Mahratta empire, the Sooties under the late Tippoo, and various other ſuch predatory eſtabliſhments, commanded by officers of a ſuitable diſpoſition, have ever been famous for annoying, and for cutting off the ſupplies of their adverſaries.

No enterpriſe, whether military or naval, ſhould be entruſted to the charge or conduct of an individual deficient in any one of the requiſites for ſuch a reſponſible, and, indeed, ſo arduous an appointment. In the firſt place, a knowledge of the geography of that country he is to infeſt, and of the language of its inhabitants, is indiſpenſably requiſite. His character for marked perſonal courage, and for the prompt application of ſuitable remedies againſt every ſpecies of diſaſter, or of diſappointment, ſhould be conſpicuous. He ſhould poſſeſs that kind of deportment which preſerves the ſtricteſt ſubordination, while it ſecures the affection, and excites the admiration, of all under his command. He ſhould be expert in all military exerciſes, and poſſeſs both an active mind, and the soundeſt conſtitution. With ſuch valuable gifts, added to a certain conciliatory mode of conduct towards the peaſantry, &c. of the diſtrict in which he is to carry on his enterpriſes, a partiſan may perform wonders, and far outdo all the exploits an equal number of regulars could achieve under a leſs capable leader. The truth is, that, generally ſpeaking, ſoldiers and ſailors are mere automatons, acting under the direction of an expert machiniſt, whoſe character is ever appreciated according to the ſucceſs of his movements. How far permanent reputation may be eſtabliſhed by the commander of ſuch an auxiliary force, may be collected from that dread which was created by the Tarleton legion among the Americans, during their ſtruggle with the mother country. That legion, even at this day, are ſpoken of in terms of admiration, by the very people who ſuffered ſo ſeverely from the exertions and abilities of its commander.

It being obvious that, on many occaſions, an army muſt depend greatly for ſupplies on the activity and talents of a partiſan, we cannot too forcibly point out the peremptory neceſſity which exiſts, for the rejection of all who may be deficient in the above qualities, without which, it is unreaſonable to expect that any enterpriſe of moment ſhould ever be ſafe to thoſe who might be employed; much leſs could it be of ſervice to thoſe in whoſe behalf it might be undertaken. Naval enterpriſes require no leſs attention in ſome caſes; though, for the moſt part, we find them rather indebted for ſucceſs to undaunted bravery, and a moderate portion of judgment. Theſe ordinarily are made under cover of, or ſupported by, ſome ſufficient force; whereby, in caſe of defeat, they are reſcued from total ruin: whereas, the military partiſan rarely has ſuch protection at hand.

ENTERSOLE. See MEZANINE.

ENTERTAIN. This term has, no doubt, crept into military phraſeology in conſequence of the entertainment afforded at public-houſes, &c. to ſuch candidates as prefer a ſcarlet coat and a muſket, to a frock and a pitch-fork. We cannot ſufficiently expreſs our regret, that no better mode has been ordinarily brought into practice, than that of plying men with liquor for the purpoſe of inducing them to inliſt. We are, indeed, rather infidels on the ſubject of any numerous acceſſions to the real ſtrength of our armies, in conſequence of this cuſtom: for we have had occaſion to learn, that a very large portion of the recruits obtained in conſequence of inebriety, either abſcond at ſome favourable moment, or prove to be the worſt ſoldiers in their regiment. If drunkenneſs has been habitual to them, they rarely relinquiſh their addictedneſs to liquor; and if, on the contrary, they had, until the moment of being inliſted, been of a ſober diſpoſition, their peace of mind is totally deſtroyed, and they ſerve without alacrity, without zeal, and generally, too, without health: they are often known to fall a prey to remorſe!

We are ſenſible that, ſpeaking abſtractedly, the affording of entertainment to perſons who appear deſirous of inliſting, may be defended under the plea of ſtate neceſſity; but it becomes a very ſerious queſtion, whether the nation does not pay conſiderably more in conſequence of the monies expended in this way? alſo, whether it is ſound policy to allow military perſons to be in any ſhape concerned in overwhelming the ſenſes of that man, who is to be for life aſſociated with them, and who will not always be unmindful of the condition to which they may have brought him? To condemn a practice, ſaid to be ſo neceſſary towards our ſafety as an independent nation, without offering a ſubſtitute of a more favourable deſcription, might, perhaps, juſtly ſubject us to the imputation of preſumptuouſly branding the exiſting cuſtom with obloquy; we ſhall, therefore, briefly remark, that, in all probability, not only as many, but more, valuable recruits would be obtained by deſiſting from what is vulgarly called *entertaining* the candidates; and from expending a very large portion of his bounty in liquor, raree-ſhows, and ſuch diſſipations as "make him poor indeed!" In place of this, let the whole of his bounty-money be given to the pariſh from which he may have been taken, for the ſupport of his family; and let the recruit himſelf be ſubſiſted and cloathed entirely at the expence of the ſtate. Should the recruit have no family ſubject to parochial aid, or likely to be ſo, let his bounty money be reſerved until he ſhould have ſerved a certain time, and then to be given to him in inſtalments; ſo that he might not diſſipate the whole adventitiouſly,

ventitiouſly, and that he ſhould be enabled, from time to time, to provide himſelf with various articles of apparel, or of comfort, ſuited to his profeſſion.

We cannot cloſe this ſubject without ſtrongly reprobating the practice of ſtopping certain ſums, for off-reckonings, and neceſſaries. If the ſoldier is to pay for them, let it be by a plain and peremptory reduction of his pay, in exchange for which he ſhould receive certain articles from government; but let there be no account-current between the ſoldier and his officer, for feathers, lace, buckles, canteens, knapſacks, and ſuch like: this kind of dealing ſets aſide that reſpect which the former ought always to entertain for the latter, and, not unfrequently, occaſions a certain kind of ſuſpicion by no means tending to promote either eſteem or ſubordination. While reform ſeems to be the order of the day, it may, perhaps, be at leaſt faſhionable, if not praiſeworthy, to point out this as an inſtance in which much melioration might be very eaſily, and ſafely, effected.

ENTERTAINMENTS, *epulæ*, among the ancients, were of various kinds, as, 1. Funeral entertainments, *epulæ funebres*. 2. Entertainments given by the huſband on bringing home his wife, called *epulæ geniales*. 3. Thoſe beſtowed on the ſoldiers, called *epulæ militares;* which was done before or after an engagement, or on occaſion of proclaiming the general imperator. 4. Birth-day entertainments, *epulæ natalitiæ*.

There were many other kinds, denominated either from the place where, the perſons by whom, or the occaſion for which they were given.

ENTERVIEW, in *Falconry*, a term uſed for the ſecond year of a hawk's age.

ENTHALIUM, in *Natural Hiſtory*, a name given by ſome to a ſpecies of the tubuli marini, more uſually known by the name of penicillum marinum, and pinceau de mer. See Penicilli *Marini*.

ENTHUSIASM, Ενθουσιασμος, a poetic, or prophetic rage or fury, which tranſports the mind, inflames and raiſes the imagination, and makes it conceive and expreſs things extraordinary and ſurpriſing.

The word is derived from the Greek, ενθεος, or ενθους, a man animated in an extraordinary manner with the ſpirit of God; in whom God is, or whom God animates. Whence the verb ενθουσιαζω, or ενθουσιαω, and the noun ενθουσιασμος, *enthuſiaſm:* and ενθουσιαστης, *enthuſiaſt*, a perſon ſubject to ſuch tranſports.

M. de Piles defines enthuſiaſm to be a tranſport of the mind, whereby it is led to think and imagine things in a ſublime, ſurpriſing, yet probable manner.

The ſublime he thinks a neceſſary ingredient in the definition, as being the proper effect and production of enthuſiaſm.

This is the enthuſiaſm felt in poetry, oratory, muſic, painting, ſculpture, &c. (ſee the next article); but this enthuſiaſm which belongs to the works of art, is very different from that attributed to the ſibyls and prieſteſſes of the oracles, and heathen gods, which was little elſe but fanaticiſm, and conſiſted principally in grimace, and contortions of the body. See Oracle and Pythian.

There is a degree of aſſent, ſays Mr. Locke, which, with ſome men, has the ſame authority as either faith or reaſon; and that is enthuſiaſm, which, laying by reaſon, would ſet up revelation without it; whereby, in effect, it takes away both reaſon and revelation, and ſubſtitutes in the room of it the ungrounded fancies of a man's own brain, and aſſumes them for a foundation, both of opinion and conduct.

Immediate revelation being a much eaſier way for men to eſtabliſh their opinions, and regulate their conduct by, than the tedious labour of ſtrict reaſoning; it is no wonder, that ſome have been very apt to pretend to it: eſpecially in ſuch of their actions and opinions as they cannot account for by the ordinary methods of knowledge and principles of reaſon. Hence we ſee, that in all ages men in whom melancholy has mixed with devotion, or whoſe conceit of themſelves has raiſed them into an opinion of a greater familiarity with God than is allowed others, have often flattered themſelves with the perſuaſion of an immediate intercourſe with the Deity, and frequent communications with the Divine ſpirit.

Their minds being thus prepared, whatever groundleſs opinion comes to ſettle itſelf ſtrongly upon their fancies, is an illumination from the ſpirit of God; and, whatſoever odd action they find in themſelves an inclination to do, that impulſe is concluded to be a call or direction from heaven, and muſt be obeyed.

This we take to be properly enthuſiaſm; which, though riſing from the conceit of a warm and over-weening brain, works, where it once gets footing, more powerfully on the perſuaſions and actions of men than either reaſon or revelation, or both together; men being moſt forwardly obedient to the impulſes they receive from themſelves.

When men are once got into this way of immediate revelation, of illumination without ſearch, and certainty without proof, reaſon is loſt upon them; they are above it; they ſee the light infuſed into their underſtanding, and they cannot be miſtaken: like the light of bright ſun-ſhine, it ſhews itſelf, and needs no other proof but its own evidence; they feel the hand of God moving them within, and the impulſes of the ſpirit, and cannot be miſtaken in what they feel. But, of this ſeeming and feeling, it is a perception of an inclination to do ſomething, or of the Spirit of God moving that inclination: theſe are two very different perceptions, and ſhould be carefully diſtinguiſhed.

If they know the thing to be a truth, they muſt do it, either by its own ſelf-evidence, or by the rational proofs that make it out to be ſo: if they know it to be a truth, either of theſe two ways, they in vain ſuppoſe it to be a revelation; for thus, all truths, of what kind ſoever, which men uninſpired are enlightened with, come into their minds. If they ſay, they know it to be true, becauſe it is a revelation from God, the reaſon is good; but then it will be demanded, how they know it to be a revelation from God? If they ſay, by the light it brings with it, they ſhould conſider, whether this be ſaying any more than that it is a revelation, becauſe they believe it to be true; for all the light they ſpeak of is but a ſtrong perſuaſion of their own minds that it is a truth, which is a very unſafe ground to proceed on, either in our tenets or actions. True light in the mind is nothing elſe but the evidence of the truth of any propoſition; and if it be not ſelf-evident, all the light it can have is from the clearneſs of thoſe proofs upon which it is received. See Evidence.

God, when he makes the prophet, doth not unmake the man; he leaves his faculties in their natural ſtate, to enable him to judge of his inſpirations, whether they be of divine original or not. If he would have us aſſent to the truth of any propoſition, he either evidences that truth by the uſual methods of natural reaſon, or elſe makes it known to be a truth which he would have us aſſent to by his authority; and convinces us that it is from him, by ſome marks which reaſon cannot be miſtaken in. Eſſay on Hum. Underſt. book iv. chap. 19.

The holy men of old, who had revelations from God, had ſomething elſe beſides internal light, of aſſurance in their own minds, to teſtify to them that it was from God; they had outward ſigns to convince them of the Author of thoſe revelations; and when they were to convince others, they had a power given them to juſtify the truth of their commiſſion from heaven; and by viſible ſigns, to aſſert the divine authority of the meſſage they were ſent with. Moſes ſaw the buſh burning without being conſumed, and heard a voice out of it. God, by another miracle, of his rod turned into a ſerpent, aſſured him likewiſe of a power to teſtify his miſſion, by the ſame miracle repeated before thoſe to whom he was ſent.

Enthuſiaſm is defined by Dr. Hartley (Obſ. on Man) to be a miſtaken perſuaſion in any perſon, that he is a peculiar favourite with God; and that he receives ſupernatural marks thereof. The vividneſs of the ideas of this claſs eaſily generates this falſe perſuaſion in perſons of ſtrong fancies, little experience in divine things, and narrow underſtandings, (and eſpecially where the moral ſenſe, and the ſcrupuloſity attending its growth and improvement, are but imperfectly formed,) by giving a reality and certainty to all the reveries of a man's own mind, and cementing the aſſociations in a preternatural manner. It may alſo be eaſily contracted by contagion, as daily experience ſhews; and indeed more eaſily than moſt other diſpoſitions, from the glaring language uſed by enthuſiaſts, and from the great flattery and ſupport which enthuſiaſm affords to pride and ſelf-conceit. The ingredients, ſays lord Lyttelton in his "Obſervations on the Converſion, &c. of St. Paul," of which enthuſiaſm is generally compoſed, are great heat of temper, melancholy, ignorance, credulity, and vanity, or ſelf-conceit.

The true ſources of enthuſiaſm, ſays Mr. Hume in his "Eſſay on Superſtition and Enthuſiaſm," are hope, pride, preſumption, a warm imagination, together with ignorance. From the influence of theſe cauſes ariſe raptures, tranſports, and ſurpriſing flights of fancy; and whilſt confidence and preſumption ſtill increaſe, theſe raptures, being altogether unaccountable, and ſeeming quite beyond the reach of our ordinary faculties, are attributed to the immediate inſpiration of that Divine Being, who is the object of devotion. In a little time the inſpired perſon comes to regard himſelf as a diſtinguiſhed favourite of the Divinity; and when this phrenſy once takes place, which is the ſummit of enthuſiaſm, every whimſy is conſecrated. Human reaſon, and even morality, are rejected as fallacious guides; and the fanatic madman delivers himſelf over, blindly, and without reſerve, to the ſuppoſed illapſes of the ſpirit, and to inſpiration from above.

Devotion, undirected, or unreſtrained by reaſon, degenerates into enthuſiaſm, or a religious phrenſy, founded in an apprehenſion of a preſent Divine energy on the mind, to which all its powers are ſuppoſed to be ſubject, and by which a perſon is carried on without attention to any thing elſe as his guide, and producing not only great perturbation of mind, but moſt amazing agitations of body. Many inſtances of this kind occur, both in ancient and modern times, to the diſgrace and injury of rational religion.

Mr. Hume (ubi ſupra) makes ſeveral reflections concerning the different influences of enthuſiaſm and *ſuperſtition* (which ſee) on government and ſociety. He obſerves, *firſt*, that ſuperſtition is favourable to prieſtly power, and enthuſiaſm not leſs, or rather more, contrary to it than ſound reaſon and philoſophy. He obſerves, *ſecondly*, that religions, which partake of enthuſiaſm, are, on their firſt riſe, more furious and violent than thoſe which partake of ſuperſtition; but in a little time become more gentle and moderate. When enthuſiaſm riſes to that height as to inſpire the deluded fanatic with the opinion of divine illuminations, and with a contempt for the common rules of reaſon, morality, and prudence, it produces the moſt cruel diſorders in human ſociety; but its fury is like that of thunder and tempeſt, which exhauſt themſelves in a little time, and leave the air more calm and ſerene than it was before. When the firſt fire of enthuſiaſm is ſpent, men naturally, in all fanatical ſects, ſink into the greateſt remiſſneſs and coolneſs in ſacred matters; there being no body of men among them, endowed with ſufficient authority, whoſe intereſt is concerned to ſupport the religious ſpirit: no rites, no ceremonies, no holy obſervances, which may enter into the common train of life, and preſerve the ſacred principles from oblivion. For the influence of ſuperſtition, ſee that article. He obſerves, *thirdly*, that ſuperſtition is an enemy to civil liberty, and enthuſiaſm a friend to it.

Enthusiasm, in *Poetry*, *Eloquence*, and *Elocution*, is a ſpecies of rapturous elevation and fervour, which tranſports the writer or ſpeaker beyond the limits of apparent rule, and mere methodical propriety. Like genuine ſublimity, to which it is very nearly allied, and with which it occaſionally co-operates, in producing the higheſt impreſſions that can reſult from human eloquence, it defies, perhaps, the exactneſs of logical definition; its very eſſence conſiſting in a ſtate of feeling, at once ſo potent and ſo evaneſcent, as to elude the cautious touch of analyſis. It belongs, therefore, only to perſons of ſuperior genius, and by ſuch alone muſt be attempted; ſince, like all ſuperlative excellencies, it verges for ever on the brink of abſurdity; and criticiſm has never yet been able to erect a ſufficient barrier to defend its utmoſt limits. Like every other paſſion, it muſt be felt before it can be expreſſed; and the mind of the writer or the ſpeaker muſt be well fortified with knowledge on the ſubject he is handling, and the judgment well exerciſed in the nice diſcriminations of taſte, of feeling, and of decorum, before he ventures to indulge it in compoſition or in delivery, if he addreſſes himſelf to the enlightened or educated portions of the community, or he will be worſe than diſappointed of his object. In circles of a different deſcription, however, it is evident that the mere ſemblance of enthuſiaſm, unaided by theſe preliminary qualifications, ſeldom fails of a very powerful effect: and, by this quality alone, bigotry and fanaticiſm frequently accompliſh their end, and maintain abſolute dominion over the minds of their ignorant votaries. It is therefore ſufficiently obvious, that it is a quality the orator, if he be ſuſceptible of it, ſhould never fail to cheriſh; and if he be not ſuſceptible of it, he is but a fragment of an orator. As for poetry, enthuſiaſm is admitted to be its very ſoul and eſſence. In the delivery of eloquence, or the recitation of poetry, genuine enthuſiaſm is expreſſed by a deep and powerful aſpiration, by an increaſe of quantity in all the ſyllables principally produced by the prolongation and increaſe of the power of the voice on the liquids and liquifiable conſonants; a reſtrained vehemence, which, without any of the diſguſting effects of vociferation, ſpreads the undulations of ſound through an extended circle. It is generally accompanied by a conſiderable dilatation of the noſtrils, a protruſion of the eye-balls, and great tenſion and rigidity of the whole muſcular ſyſtem. Shakeſpeare, who felt its influence ſo frequently, has finely deſcribed its operation in the ſpeech of Henry V. before Harfleur:

> "Now ſet the teeth, and ſtretch the noſtrils wide,
> Hold hard the breath, and bend up every ſpirit
> To its full height."

The whole ſpeech is one of the fineſt effuſions of enthuſiaſm ever penned, and requires in the reciter all the inſpiration of that powerful feeling.

ENTHUSIAST, Ενθυσιαστης, a perſon poſſeſſed with enthuſiaſm. See Enthusiasm, Fanatic, &c.

The word is generally underſtood in an ill ſenſe. It was applied by the ancients to a ſect of heretics, called alſo Maſſalians and Euchites; who, as Theodoret expreſſes it, were denominated enthuſiaſts, becauſe being poſſeſſed by the devil, they believed themſelves divinely inſpired. See Massalians and Euchites.

Among us, enthuſiaſt is ſometimes of like import with fanatic, and is applied to the Quakers, and ancient Anabaptiſts, and modern prophets, from their pretences to extraordinary lights, revelations, viſions, impulſes, &c. from heaven.

ENTHYMEME, in *Logic* and *Rhetoric*, an argument conſiſting only of two propoſitions, an antecedent, and a conſequent deduced from it.

The word is Greek, ενθυμημα, formed of the verb ενθυμεισθαι, to think, conceive, a compound of εν and θυμος, *mind*.

Ariſtotle calls it the rhetorical or probable argument; the ſchools, the imperfect ſyllogiſm, in contradiſtinction to the perfect, which conſiſts of three propoſitions, and is called the dialectical argument.

It muſt be obſerved, however, that the enthymeme is really a perfect ſyllogiſm in the mind, and only imperfect in the expreſſion, becauſe one of theſe premiſes is ſuppreſſed, as being ſufficiently clear and obvious, and eaſily ſupplied by the underſtanding of thoſe with whom we diſcourſe.

Thus, in every right-lined triangle, the three angles are equal to two right ones; and conſequently, they are ſo in an iſoſceles triangle, is an enthymeme; the propoſition, that an iſoſceles triangle is a right-lined triangle being omitted, as being ſufficiently known and granted.

The enthymeme is the moſt ſimple and elegant of all argumentations; being what a man, in arguing cloſely, commonly makes, without attending at all to the form. Thus, that verſe remaining of Ovid's tragedy, entitled Medea, contains an enthymeme: "Servare potui, perdere an poſſum rogas:" "I was able to ſave you; conſequently, to have deſtroyed you." All the beauty would have been loſt, had all the propoſitions been expreſſed; the mind is diſpleaſed with a rehearſal of what is no ways neceſſary.

Sometimes, alſo, the two propoſitions of an enthymeme are both included in a ſingle propoſition, which Ariſtotle calls an enthymematical ſentence, and gives this inſtance thereof: "Mortal, do not bear an immortal hatred." The whole enthymeme would be, "Thou art mortal; let not, therefore, thy hatred be immortal."

ENTIER, in the *Manege*, is uſed for a ſort of reſty horſe, that refuſes to turn, and is ſo far from following or obſerving the hand, that he reſiſts it. If your horſe is entier, and refuſes to turn to what hand you will, provided he flies, or parts from the heels, you have a remedy by putting the Newcaſtle on him; that is a caveſſon, made after the duke of Newcaſtle's way.

The word is French, and is alſo uſed among them to denote a ſtone-horſe.

This term, in its common acceptation, is applied to a horſe that refuſes to turn, and whoſe refuſal proceeds from the awkwardneſs and ſtiffneſs of the body and limbs, and ſometimes from malice and bad habits. In ſome caſes, a hurt in his foot, leg, or ſhoulder, may be the cauſe of his refuſing to turn to that ſide where he feels any pain. A hurt in his reins or haunches, a curb or ſpaving, which, by hindering him to bend and reſt upon his hocks, may make him guilty of this diſobedience. Theſe are evils which art can do little towards curing. The term entier, in its figurative ſenſe, in which it is always to be underſtood in horſemanſhip, means a ſtiff horſe, or one that is not ſuppled, and therefore refuſes to turn, from the pain and difficulty which he finds in putting himſelf into a proper poſture. Accordingly the Italians, from whom the terms of horſemanſhip are chiefly taken and adopted, or naturalized by other nations, figuratively call a ſtiff and undiſciplined horſe, a whole, entire, or unbroken horſe; which, from the ſtiffneſs and tightneſs of his joints and muſcles, is not able to bend himſelf, but in turning moves all of a piece, like a beam, or bar of iron; while the active and ſuppled horſe, who can bend himſelf readily, and becomes part of the circle he deſcribes in turning, may be ſaid, like a chain, ſo to looſen and ſhift his limbs, as to break and divide himſelf, as it were, into parts; whence, perhaps, the term "horſe-breaker," for one who forms the paces, and qualifies horſes for being rode. Berenger's Hiſtory and Art of Horſemanſhip, vol. ii.

ENTIERTIE, from the French *entier*, is uſed in our *Law-books*, in contradiſtinction to moiety, and denotes the whole. Thus a bond, damages, &c. are ſaid to be entire, when they cannot be divided or apportioned.

ENTIRE Leaf, in *Syſtematic Botany*, *folium integerrimum*, a leaf whoſe edge is not cut or toothed; the term has no reference to *folium integrum*, an undivided leaf, which laſt is deſtitute of lobes or ſegments, without regard to its margin.

Entire *Tenancy*, in *Law*, is contradiſtinguiſhed to *ſeveral tenancy*, and ſignifies a ſole poſſeſſion in one man; whereas the other denotes a joint, or common one, in ſeveral. See Tenant and Joint-tenant.

Entire *Arms*. See Arms.

ENTITATIVELY, Entitative, implies an abſtraction, or ſeparation of all the circumſtances, from a thing under conſideration.

Thus, a thing is ſaid to be taken or conſidered entitatively, or ſecundum entitatem, when conſidered nakedly and preciſely, according to what it is in itſelf, without any thing extrinſic. *E. gr.* Peter entitatively taken, is Peter, as a thing, a ſubſtance, a man, &c. without any regard to his being a lord, a huſband, learned, &c.

ENTITY, in the *School Philoſophy*, a phyſical ens, or being, conſidered according to what it is in its natural capacity.

Some dealers in diſtinctions give us ſeveral kinds of entity.

Or, entity denotes the actual eſſence or exiſtence of any thinking thing. See Ens.

ENTLIBUCH, in *Geography*, a village of Switzerland, in the canton of Lucern, the principal place of a bailliage, which extends from the Emme-thal in the canton of Bern to the bridge near Wertenſtein, about 15 miles in length and 9 in its greateſt breadth; and contains 11,000 perſons. It is governed by a bailiff, who is always a ſenator of Lucern; he continues in office two years, and generally reſides in that capital. The bailliage is divided into three diſtricts; the upper, or Eſchliſmat, the middle, or Shuepfen, and the lower, or Entlibuch; each of which has its ſeparate courts of juſtice, from which an appeal lies to Lucern. The valley of Entlibuch is watered by ſeveral rivulets, winding for ſome way between two ridges of well-wooded hills, and abounding in pictureſque ſcenery. It contains ſeveral villages, of which the principal are Eſchliſmat, Shuepfen, and Entlibuch, which takes its name from the river Entle, and gives it to the whole diſtrict. The inhabitants chiefly follow

low agriculture; they rear large quantities of horned cattle, ſheep, goats, and ſwine; they alſo make and export cheeſe in great abundance. The peaſants of Entlibuch are much eſteemed for their independent ſpirit, vigour, and ſtrength; and are remarkable for keenneſs and vivacity, for great quickneſs in repartee, for a peculiarity of garb, and for many ſtriking cuſtoms, which diſtinguiſh them from the natives of circumjacent diſtricts. The valley of Entlibuch may be conſidered as one of thoſe parts which unite with the mild and cultivated the wild and rugged ſcenery of Switzerland; its acclivities gradually aſcend and terminate in mount Pilate, whoſe barren top is ſeen towering above the fertile and well-wooded hills. In the 13th century, Entlibuch was ſubject to the counts of Wolhauſen, and came by purchaſe, in 1299, to the emperor Albert. In the following century it was held as a fief from the houſe of Auſtria by ſeveral ſucceſſive counts; till the nation, grievouſly oppreſſed by Peter of Torrenberg in 1386, threw itſelf under the protection of Lucern. That republic continued to poſſeſs Entlibuch, as a feudal tenure under the houſe of Auſtria, till the year 1405; when the archduke Frederic renounced all the rights of ſovereignty. For above a century and a half, the inhabitants, inflamed with a deſire of independence, and excited by the example of the popular cantons, frequently roſe in arms, and attempted to eſtabliſh a democracy, but without ſucceſs. Their laſt inſurrection broke out in 1653; ſince which time they have continued in a ſtate of perfect tranquillity under the adminiſtration of Lucern, enjoying, with contentment, the privileges with which they are endowed. The peaſants of Entlibuch were diſtinguiſhed by their attachment to the government, and by their decided oppoſition to French principles, during the late revolution. Coxe's Travels in Switzerland, vol. i.

ENTOGANUM, in *Botany*, Gærtn. t. 68. See Melicope.

ENTOMOLITHUS, in *Natural Hiſtory* and *Mineralogy*, is the name of a genus of the animal order of remains (*reliquia*, or relicts) of a former race of beings, which inhabited the earth or its waters, and includes the different kinds of inſects found in a foſſil ſtate. According to Mr. William Martin (Outlines of the Knowledge of extraneous Foſſils, p. 191), the eſſential characters, or diagnoſtics of the permanent ſpecies in this genus, are to be ſought, in "the upper external covering of the thorax, united to that of the abdomen;" the temporary ſpecies of this genus are to compriſe the detached head, thorax, abdomen, limbs, &c. of foſſil animals, reſembling the recent ſpecies of inſects. See Reliquia.

ENTOMOLOGY, the ſcience of inſects, or, as literally rendered from the Greek, a *diſcourſe on inſects*; the term by which the ſtudy of theſe animated beings is expreſſed.

Inſect, from *inſectum*, Latin, is of later origin than ἔντομα, the term made uſe of by Ariſtotle, who flouriſhed in the fifth century, before the Chriſtian era, and was invented much earlier than the time of that celebrated philoſopher. Ariſtotle defines it to ſignify an animal which by inciſions is nearly ſevered into two or more parts, and the Latins, long before the time of Pliny, (who lived in the reign of Titus,) employed the word *inſectum*, from *inſecor*, which preciſely bears the ſame interpretation.

The inſect race conſtitutes the moſt conſiderable portion of the whole claſs of organized bodies poſſeſſing the vital principle of life. The number of aquatic beings concealed from our reſearch in the depths of the ocean cannot be within the reach of human eſtimate; it is to the terreſtrial tribes, or thoſe which inhabit the ſurface of our globe, that we alone allude; and the entire amount of theſe, including every order, is confeſſedly inferior in point of number to the ſingle claſs of inſects. Among the larger animals the diſcovery of a few new ſpecies, or of individuals not correctly aſcertained before, is eſteemed of conſequence; but ſo extenſive are the limits of entomology, that the diſcovery of a multitude of inſects under the ſame circumſtances fail to excite aſtoniſhment, though it may awaken curioſity; and, indeed, its frequency ſeems calculated to confirm the commonly received opinion, that the inſect race, in the diverſity of ſpecies, much more in the number of its individuals, muſt be almoſt boundleſs.

In this view the ſcience of entomology becomes one of the moſt important that can engage the mind of the natural philoſopher. It is the difficulty of diſcriminating the particular affinities and characters of theſe beings, ariſing from their amazing number and variety of form, in addition to their minuteneſs, that more ſtrongly enforces their claim to his conſideration. The naturaliſt who neglects the ſtudy of inſects, cannot deſerve our reſpect as a general obſerver of nature. His views are partial; his enquiries circumſcribed; he regards only an inconſiderable portion of animated nature; and his remarks are confined chiefly to thoſe which, from their magnitude and diſtinctneſs of character, preſent the leaſt obſtacle to inveſtigation.

The ſtudy of every claſs of animals is indiſputably attended with peculiar advantages; and in none is this aſſurance more clearly manifeſted than in the tribe of inſects. In the mazy labyrinths of entomology, the naturaliſt will find abundant ſcope for the exerciſe of his zeal and application, and in the courſe of his enquiries the full exertion of his penetration will be oftentimes required to the aſcertainment of truth. The amazing number of ſpecies it embraces; their forms ſo extraordinary; ſo infinitely varied; and yet ſo gradually approximating through an endleſs ſeries of tranſitions from one ſpecies to another; the diverſity of ſtructure obſervable in their antennæ, their limbs, bodies, wings, and every other particular which conſtitute the eſſential differences of their orders, genera, and ſpecies; added to the ſurpriſing changes in form which the generality of inſects undergo at ſtated periods of their life:—theſe are circumſtances which contribute to render them objects of the moſt curious ſpeculation to the naturaliſt, and we ſhall venture to affirm, that it is from a knowledge of theſe, their characters, tranſitions, metamorphoſis, and the various modes of life theſe little beings are deſtined to purſue, that he will obtain a more intimate acquaintance with the great laws of animated nature, than can poſſibly be derived from the contemplation of any other tribe in the creation.

As inſects ſurpaſs all other animals in their number, variety, and ſingularity, ſo alſo it is a natural inference that they muſt deſerve the greateſt ſhare of attention. The hiſtory of theſe creatures abound with the moſt valuable information in a philoſophic view, and ſtrongly recommend the ſtudy to the attention of every curious obſerver. Entomology poſſeſſes many other attractions, ſome at leaſt of which have not been well conſidered. The only one to which we ſhall particularly advert at this moment, is the beauty of inſects in general, a point on which there can be no difference of opinion. Theſe little creatures are rendered engaging from the gaiety of their natural hues: from combining oftentimes with the moſt graceful forms a diſplay of colouring very far excelling in ſplendour, vivacity, delicacy, and harmony of diſpoſition, that beſtowed by the hand of nature on her other works. One defect in their appearance muſt be nevertheleſs conceded; and this may be regarded in point of beauty as a material deficiency indeed: they are not always ſo conſiderable in magnitude, as to become, even with theſe embelliſhments, ſtrikingly attractive: were they only equal in ſize to the minor tribes of birds and animals, their unrivalled elegance would certainly render them objects of high eſteem in the general opinion of mankind.

But the diminutiveneſs of inſects ought to operate in a contrary manner on the mind of the philoſopher. While this cauſe oppoſes the greater difficulty to the ſtudy, it ſhould more ſtrongly incite inveſtigation. This we are aware is not always conſidered as an inducement, and the diminutiveneſs of theſe creatures has been ſometimes urged as a reaſon that they do not merit the attention beſtowed upon them. However injudicious this opinion ought in candour to be conceived, it has obtained the countenance of many; and among the number, of ſome men at leaſt who, from their ſuperiority of talent, might be deemed incapable of advancing ſuch an argument againſt the ſtudy of any department of natural ſcience. Thus the ingenious Buffon, whoſe attention, as is well known, was reſtricted to the larger tribes of animals, intimates its inferiority in language ſufficiently pointed. "Who (ſays this lively author) gives us the grandeſt and moſt magnificent ideas of the creator of the univerſe? he who repreſents him in the plenitude of his power, directing the formation of ſuns and of planets, and guiding the revolutions of worlds, or he who diſcovers him buſied in regulating the economy of a hive of bees, or deeply engaged in folding the wings of a beetle?"

How different is this from the ſentiments expreſſed by other philoſophers, who, with more enlarged and liberal views, have held every branch of natural ſcience in its proper eſtimation! There are many who even aſſign a higher degree of perfection to the inſect race than to other claſſes of animals. We learn the opinion of Pliny from his own words. "In his tam parvis tamque fere nullis quæ ratio! quanta vis! quam inextricabilis perfectio!" Boyle declares, that for his own part his wonder was more excited by the contemplation of a mite than an elephant; and Reaumur ſpeaks more decidedly to the ſame effect, in language worthy of repetition. Pourquoi, (ſays this author,) craindrions-nous de trop louer les ouvrages de l'Etre Suprême? Une machine nous paroît d'autant plus admirable, et elle fait chez nous d'autant plus d'honneur à ſon inventeur, que, quoiqu' auſſi ſimple qu'il eſt poſſible par rapport à la fin à laquelle elle eſt deſtinée, il entre dans ſa compoſition un plus grand nombre de parties, et de parties très-différentes entre elles. Nous avons une grande idée du génie de l'ouvrier qui a ſu réunir et fait concourir à la même fin, autant de parties différentes et néceſſaires. Celui qui a fait, les machines animées que nous appelons des inſectes, n'a aſſurément fait entrer dans leur compoſition que les parties qui devoient y être. Combien, malgré leur petiteſſe, ces machines nous doivent-elles paroître plus admirables que celle des grands animaux, s'il eſt certain qu'il entre dans la compoſition de leur corps beaucoup plus de parties qu'il n'en entre dans celle des corps énormes des élephans et des baleines! Pour faire paroître au jour un papillon, une mouche, un ſcarabée, en un mot, tous les inſectes, qui ont à ſubir des transformations, il a fallu au moins faire l'equivalent de deux animaux, faire une chenille dans laquelle le papillon prit tout ſon accroiſſement, faire des larves dans leſquelles la mouche et la ſcarabée puſſent croître". Swammerdam is impreſſed with the ſame idea. "After an attentive examination (ſays this writer) of the nature and anatomy of the ſmalleſt as well as the largeſt animals, I cannot help allowing the leaſt an equal or perhaps a ſuperior degree of dignity to the former. If, while we diſſect with care the larger animals, we are filled with wonder at the elegant diſpoſition of their parts, to what an height is our aſtoniſhment raiſed, when we diſcover all theſe parts arranged in the leaſt, in the ſame regular manner! Notwithſtanding the ſmallneſs of ants, nothing prevents us from preferring them to the larger animals, if we conſider either their unwearied diligence, their wonderful ſtrength, or their inimitable propenſity to labour."

Another objection, for we ſhall not term it argument, has been advanced againſt this ſtudy, the validity of which cannot be ſo thoroughly examined in this place as we could wiſh; it has been ſtated, that becauſe inſects furniſh few of the articles of life they deſerve no conſideration. This is the language of ignorance, and ſuch as we could eaſily ſhew to be of the moſt futile kind. The ſtudy of theſe creatures is as replete with utility; and the knowledge of them as eſſential to the benefit of mankind, as moſt other branches of ſcientific purſuit; nor ſhall we ſcruple to aver, that in this particular reſpect entomology claims a decided ſuperiority over every other department of zoology. But the fact is evident, that the importance of this ſcience, at leaſt in Britain, has never been duly appreciated, and this ariſes from the moſt obvious of all cauſes, that it has not been ſufficiently explained.

Inſects may properly be divided into two kinds, thoſe which are either directly or remotely beneficial, or injurious to the purpoſes of mankind. Many inſects, it is true, do not ſeem to affect us in any manner; but appearances in this reſpect, let it be obſerved, are not always to be relied upon. Others, and the number of thoſe is very great, moſt aſſuredly fall within the denomination of one or other, and even both the firſt mentioned kinds, and for this reaſon ought ſurely to demand our attention. In the ordinary concerns of life it is deemed of as much, if not greater conſequence, to know our enemies, and aſcertain the powers of annoyance they poſſeſs, as it is to learn what benefit we may be able to derive from our friends: let us apply this plain and rational argument to the ſtudy of inſects, and we think it will appear equally conſiſtent, when we aſſert that it is as important to know thoſe which are injurious to our intereſts, as thoſe which contribute to our advantage. When we are convinced in what reſpects particular inſects have the means of doing us injury, we may guard againſt their attacks, or apply a remedy to the evil, and if we neglect to obtain thoſe ſervices from the beneficial kinds which they are deſigned by nature to afford us, it can be no proof of our wiſdom.

Leſt, to the ſuperficial obſerver, our alluſion to the utility of inſects ſhould appear theoretical, while the noxious propenſities of others may be too fully experienced in the affairs of agriculture, horticulture, and throughout the various branches of domeſtic economy, to admit of doubt, we ſhall be more explicit in this obſervation. The ravages of inſects upon vegetation are detrimental to us; but let it be remembered alſo, that even in theſe depredations they ſometimes repay the injury they commit. The locuſt itſelf, the moſt deſtructive of all inſects, and whoſe myriads ſpread deſolation through the vegetable world, are not unproductive of advantage, except on ſome very extraordinary occaſions, when their multiplication exceeds all bounds. At other times they deprive mankind of a certain portion of his vegetable food, and, in return, their bodies afford him animal nutriment of a wholeſome and palatable kind, and in infinitely greater abundance. The various ſorts of locuſts are the common food on which the inhabitants of many parts of the world, at particular ſeaſons, chiefly ſubſiſt. The honey of bees, both of the wild and domeſtic kinds, conſtitute another primary article of food in many warm countries, in the preſent as in ancient times. The hydromel of the Ruſſians, an excellent and delicious drink, is prepared from honey, as our beverage is from malt. The various tribes of ſilk worms, (for of this kind there are ſeveral ſpecies,) furniſh materials for the raiment univerſally worn by all ranks in the eaſtern parts of the world, and hence in thoſe countries the ſilky produce of theſe induſtrious little beings is of as much real conſequence to them, as the fleecy coat of the ſheep is to us the ſtaple article of clothing; as an object of traffic, ſilk is one of the utmoſt importance in China and Tartary, and in thoſe parts the paper in common uſe is alſo manufactured from the refuſe of the ſame material. The extenſive uſe of wax in all ages is well known; but it is leſs generally underſtood that wax is not the produce of the bee alone; the wax inſect of China is a very different creature, a ſpecies of cicada in the larva ſtate, and which, with the addition of a vegetable oil, forms the mixture of which the candles of that country conſiſt. (Donov. Inſ. China.) Certain inſects are employed with ſucceſs in medicine, and a further number might be applied to the ſame purpoſe; many others might be alſo rendered uſeful in the arts, and laſtly, we need only advert to the valuable properties of the different ſpecies of cochineal in the art of dyeing, to prove the abſurdity of an opinion very generally prevalent among us, that inſects are a race of creatures too inſignificant to deſerve the notice of mankind!

But, were all theſe benefits unknown; and allowing that the ſtudy of inſects did not ſeem to be productive of any ſubſtantial advantages, how abſurd would it ſtill be to treat ſuch a fair and extenſive portion of the creation with neglect. The objection that they are in no manner conducive to our intereſts, even if founded in truth, would be no evidence of the frivolity of the ſcience itſelf, unleſs we are to conclude that the only enquiries which merit the rational attention of mankind, are thoſe which tend to the gratification of ſelfiſhneſs. If this be admitted as a plauſible objection, how many objects of philoſophical inveſtigation muſt be rejected as frivolous!

From the earlieſt period of which any authentic records remain, this race of animals has obtained the attention of every civilized age. The ſtudy of theſe creatures has not aſſuredly been cultivated with equal ardour at all times, nor has every country produced entomologiſts of conſiderable talent. It will be ſufficient to ſhew, that the ſcience itſelf has never remained in utter neglect, from the remoteſt period in which the light of natural knowledge dawned upon the intellectual horizon of man. The experience of all ages diſtinctly proves the charge of frivolity to be inapplicable to this ſtudy: many advantages, beſides thoſe above enumerated, have been, and continue ſtill to be, derived from this ſource; and it is furthermore deſerving of our obſervation, that among the number of its votaries in diſtant periods of the world, we trace the names of the moſt diſtinguiſhed characters that adorn the page of hiſtory. Perhaps we are at this moment addreſſing, among the circle of our readers, ſome at leaſt who, nurtured in habitual indifference towards the ſubject under diſcuſſion, have incautiouſly fallen into the error of conſidering it as a trivial purſuit. But we are not without expectation, that even the ſlight obſervations which the limits of our paper allow, will direct their attention with more liberality towards this ſubject, and we ſhall not heſitate to think in the reſult of this, they will eaſily conceive much ſtronger arguments in its favour than we have adduced. To the idle, or the thoughtleſs confirmed in prejudice, it would be in vain to offer any reaſon in its behalf, and to thoſe we ſhall obſerve with brevity, that whatever opinion they may be inclined to entertain of its frivolity, the ſcience of entomology will be found in every civilized age and country to have engaged the ſtudy of men endowed with talents as ſplendid and judgment as refined, as the moſt exalted for ability among thoſe who affect to treat it unworthily.

Theſe obſervations opportunely introduce to our conſideration a review of thoſe writings which have contributed to enlighten the paths of ſcience in this particular ſtudy. The number of theſe; the value and intereſt which muſt unavoidably attach to their contents; and the names of thoſe illuſtrious characters by whom many of them were produced, will fully ſanction, it is preſumed, the aſſurances before advanced. Theſe works, even in point of number alone, we have no doubt will be found infinitely more conſiderable than moſt imagine; and this circumſtance, independently of any other, tends to prove that we are not ſingular in our commendation of entomology either as an inſtructive or uſeful ſcience; as morally, and intellectually beneficial; for thoſe who write on any ſubject like the preſent, muſt be impreſſed with ſome idea of its importance, and theſe opinions may be collected uniformly from the labours of writers on the ſtudy of inſects.

As we deem this ſubject of conſequence, it is our decided wiſh, even in the curſory view to which our limits are reſtricted, not to omit the mention of any work, however ſlight, that has been productive of material information. Our ſtrictures, it will be underſtood, are confined to thoſe we have had ſufficient opportunity to conſult with ſome attention; for this we conſider due, in candour, to the reſpective writers whoſe labours are devoted to the elucidation of ſcience. Sometimes we may be inclined to expreſs ourſelves with warmth in favour of merit, neglected, forgotten, mouldering in decay, or which, from latent motives, has never been ſufficiently appreciated by later authors. If we err in this, let it be remembered, that in the truth of criticiſm we oftentimes evince more judgment in beſtowing praiſe, than awarding cenſure. But we wiſh it to be explicitly underſtood, that we do not conſider it within our province, at preſent, to enter at large upon a critical analyſis of the multitude of writings before us. Our only object is to point out the exiſtence of the moſt valuable works that are extant within our own knowledge, deſcribing at the ſame time the leading intention of their authors reſpectively: the collateral remarks can be only thoſe immediately incidental to ſuch inveſtigation. The ſeveral works enumerated will be adverted to, as nearly as poſſible, according to the order in which they appeared before the world; and hence our review, however curſory, will be attended with this peculiar advantage, that it will ſerve to point out the progreſſive improvements the ſcience has derived from the labours of each ſucceeding author, in a more perſpicuous form than could perhaps be accompliſhed in any other manner. It will alſo by this means be found calculated to afford the general reader

An Hiſtorical view of the Riſe, Progreſs, and Preſent State of Entomology.

The deſtruction of the great public libraries of antiquity has for ever deprived us of the means of aſcertaining preciſely to what ſtate of perfection this branch of ſcience had attained, till within about two thouſand years of the preſent period. Of thoſe times a few ſcanty memorials alone remain, ſufficient, however, to teſtify that the ſtudy of inſects had then made ſome progreſs, and was held in eſtimation. Whatever may be our ideas with regard to ſtill earlier times, it would be needleſs to obtrude them in this place. We ſhall obſerve only, that ſome books muſt have been written on the ſubject before the exiſtence of thoſe which have deſcended down to us: the reputation of ſuch writings is preſerved, and in certain inſtances the names of authors recorded in the very earlieſt of thoſe works at preſent extant, which clearly demonſtrates the truth of this opinion. Time has not ſpared the labours of any writer on this ſubject of more remote date than the third, fourth, and fifth century before the Chriſtian era, and the amount of thoſe which have ſurvived is ſmall indeed ; but inconſiderable as they are, in point of number, we may, notwithſtanding, collect from them that the ſtudy of inſects, in thoſe days, held a rank among the liberal purſuits of their philoſophers.

We may, indeed, proceed ſtill farther in this retroſpect, if the ſacred writings of the Hebrews be conſidered. Theſe abound with paſſages relating to particular kinds of inſects, as the locuſt, the caterpillar, flies, and vermin. Moſes, the earlieſt of the inſpired writers, had probably acquired ſome knowledge of this ſubject, in common with the other ſciences, from the ſages of Egypt ; and among the books of Solomon, now loſt to the world, it is recorded that he treated on inſects, or "creeping things."

Hippocrates flouriſhed in the 80th Olympiad, or fifth century before the Chriſtian era ; he wrote on inſects, as we are told by Pliny, in whoſe time ſome remains of the entomological obſervations of this celebrated character were probably extant. The writings of the early Greek and Latin writers, quoted by Pliny, afford extracts from this production of his labour.

The ſucceeding age gave birth to that diſtinguiſhed natural hiſtorian and philoſopher Ariſtotle : the production of whoſe labour, his hiſtory of animals, is worthy of the patronage beſtowed on its author by the conqueror of the univerſe. No one can impartially peruſe this ineſtimable treaſure of antiquity without confeſſing the intimate knowledge its writer muſt have poſſeſſed of the great arcana of nature.

This work of Ariſtotle is rather of an elementary kind, embracing a general, wide, and comprehenſive view of the animated creation, and does not, except on particular occaſions, deſcend to the deſcription of individuals or ſpecies. The inſect tribe is treated under different points of compariſon and view in ſeveral parts of the work. In the ſeventh chapter of his firſt book, he informs us, that the name ἔντομα is generic, or that of a family, and that they conſtitute one of his four orders of exſanguineous animals, and points out with great accuracy in what reſpect they differ from the molluſca, cruſtacea, and teſtacea, the other three families of this claſs of animals. By exſanguineous he means only that they have no red blood, for he ſpeaks generally to their bodies being retained in a ſtate of moiſture by other fluids. The firſt chapter of the fourth book affords a definition of the eſſential character of inſects, which conſiſts in the inciſions or cuts either on the back or belly, and ſometimes on both, by which their bodies appear to be almoſt divided into two or more parts. But that portion of his work which is more particularly devoted to inſects, is entitled Περι τῶν ἐκτὸς χο ρίων τῶν ἐν τόμων. In this he more fully deſcribes inſects to conſiſt of three parts, the head, trunk, and belly or abdomen ; the ſecond part, or trunk, is denominated an intermediate portion, correſponding with the back and breaſt in other animals ; and he alſo mentions as a character of inſects that they are furniſhed with feet.

The ſubſequent paſſages deſcribe different genera, or, as termed, tribes of inſects, in which he treats of thoſe which fly and thoſe which walk. Among thoſe furniſhed with wings, he ſpeaks of ſome having theſe parts entirely naked, and others that have them protected by a ſheath, or covering, as in the beetle kind : as he furthermore ſtates, that in ſome beetles theſe ſheaths divide or open when the inſect flies, and that in others they are inſeparably united. The inſects which have naked wings, he obſerves, poſſeſs either four, as in the bee, or two, like the muſca or common fly. Some of thoſe with four naked wings have ſtings at the end of the body, while beetles, and inſects with two naked wings, are deſtitute of this apparatus ; but ſome of the latter, he tells us, have a proboſcis or inſtrument at the mouth, by means of which they draw blood from other animals. The horns before the eyes (by which he means the antennæ) attract his obſervation, and thoſe of the papiliones and grylli are particularly deſcribed. In his remarks on the different ſtructure of the feet, thoſe formed for leaping are exemplified by thoſe of the locuſt, and are compared to the poſterior feet of ſpringing animals. The humming noiſe of certain inſects in flight, the eruca, and various other circumſtances relative to this claſs of animated beings, have intereſted the philoſopher in this chapter.

The attentive entomologiſt will feel deeply ſenſible of the accuracy of every expreſſion, thought, and ſentiment, implied in the above-mentioned paſſages. He will be ſurpriſed at their conſiſtency. Their accordance with the entomological definitions of the beſt modern ſyſtematiſts will excite farther compariſon ; and in the reſult of this inquiry it muſt be obvious, that with the acquired knowledge of two thouſand years ſince his time, ſo far as he does proceed, we cannot materially amend his obſervations. This will be admitted ; and at the ſame time we believe even a curſory peruſal of the whole work will ſerve to ſhew, that whatever might be the merits of Ariſtotle, and we allow them to be tranſcendent, theſe writings evince too much acquaintance with the ſcience of nature, to be the produce of any individual genius ſhining with unborrowed light. When we reflect upon the ſlow and gradual progreſs with which all human knowledge is developed, we are really convinced that the ſcience of nature muſt have made ſome conſiderable advancements before his time ; and that he has derived many eminent advantages from conſulting the works of more ancient naturaliſts : men whoſe original labours have been loſt to poſterity for ages, and the only traces of which at preſent extant are to be found embodied in his pages.

Ælian, in his work on animals, ΠΕΡΙ ΖΩΩΝ ΙΔΙΟΤΗΤΟΣ, appropriates ſeveral detached chapters to particular kinds of inſects, without entering in a methodical manner into the hiſtory of the tribe. Thoſe he does include are deſcribed with attention : as, for inſtance, the ſcorpions, Σκορπίων ; ants, Μυρμήκων ; ſpiders, Ἀράχνα ; crickets, Τεττίγων ; the generation of waſps, Περὶ τῆς Σφηκῶν γενέσεως ; of cantharides, τῶν καλεῖων Κανθαρίδων, &c.

The Greek poet Phile, called alſo, from his ſuperior knowledge of natural hiſtory, "Phile Sapientiſſimi," introduces ſome pleaſing poetical effuſions relative to inſects among his poems on animals. The manners of the cicadæ, and the bees, τεττίγων, and μελισσῶν, are very prettily deſcribed in verſe by this writer. He entertains the ſame idea as Ælian, that the cicadæ, by which he means the cricket, (not the inſect named cicada by Linnæus,) lived on dew ; and that the female was mute, while the male "enchanted the grove with the harmony of ſong." He ſpeaks alſo of the lampyris, and various other inſects. The beautiful ode of Anacreon to the cicada is familiar to many.

Among the Greek writers who immediately, or within a few centuries after, followed Ariſtotle in treating upon inſects, were Democritus, Neoptolemus, Ariſtomachus, Philiſtus, Nicander, Menecrates, Dionyſius Mago, Empedocles, Callimachus, Attalus, Apollodorus, Eriphilus, Eraſiſtratus, Aſclepius, Themiſo, Poſidonius the ſtoic, Meander of Priene, Euphronius of Athens, and Meander of Heraclea, Theophraſtus, and Heſodius. Theſe were authors after the time of Ariſtotle, and preceding or contemporary with Pliny. The Latin writers, during the ſame interval, were alſo numerous, and appear to have been influenced to purſue this ſtudy in imitation of the Greeks, or were inſenſibly led into it from attending to the culture of bees. The moſt eminent among the latter were M. Varro, Hyginus, Scropha, Sarcana, Celſus Cornelius, Æmilius Macer, Virgil, Columella, Julius Aquila, Tarquilius, Umbritius, Cato Cenſorius, Domitius, Calvinus, Trogus, Meliſſus, Favonius, Fabianus, Mutianus, Nigidius, Manilius, and Opius. The cultivation of bees was attended to in thoſe times with the moſt enthuſiaſtic ardour, and their hiſtory detailed by many eminent writers. We are told that Ariſtamachus of Soli wrote upon this ſubject, from the reſult of ſixty years experience; and that Philiſcus the Thaſian acquired the name of Agrius, from having employed his whole life in foreſts and deſerts, attending to theſe inſects. The culture of ſilk-worms was another favourite object with the ancients, as we learn from Pliny, who relates that in his days garments of ſilk were greatly admired by the fair ſex, becauſe, from the delicacy of its texture, it diſplayed the beauty of their perſons almoſt as diſtinctly as though they were naked.

The eleventh book of Pliny treats of inſects, as the moſt ſubtle of all animals in nature. He ſpeaks of thoſe which fly; ſome with naked wings, and others with wings protected by a covering, as Ariſtotle had previouſly obſerved. The bees, waſps, hornets, ſpiders, graſshoppers, locuſts, ants, &c. are among the number of inſects deſcribed by this writer.

From the time of Pliny till the overthrow of the Roman empire, a period of ſeveral centuries, the ſcience of inſects ſeems to have made ſome progreſs, though to what extent we may probably never learn. The names of writers in thoſe times, and ſome few ſcattered memorials of their labours, are to be found recorded in the voluminous works of authors that appeared at the revival of learning in the ſixteenth and following century. The number of theſe could not have been very inconſiderable: among the principal of them were Ætius, Paulus Ægineta, Alexander, Trallian, and Oribaſius.

The laſt-mentioned authors lived between the fourth and ſeventh century. After this time, through the dark ages, while ignorance in every ſcience prevailed nearly over the whole world, this ſtudy might have been little attended to. But we are not to conclude that even during this time it was utterly neglected. Learning had then taken a retrograde courſe from Greece and Rome towards thoſe eaſtern regions, from whence they had originally emanated; and the ſciences, during this interval, were cultivated with ſome ſucceſs in Arabia. The advancement made by the Arabians in the ſtudy of botany, between the ninth and twelfth century, is known to have been rather conſiderable. Among the entomologiſts of thoſe ages we recognize ſome of thoſe Arabian botaniſts; ſeveral of whom were diſtinguiſhed for their acquaintance with plants, as Rhazes, Avicenna, Avenzoar, and Averrhoes, each of whom wrote on inſects.

From the twelfth to the fifteenth century, a darker period than the preceding, there are few writers on this ſubject. The principal of thoſe, at leaſt within our knowledge, during this period, are Myrepſus, Hildegardis, Platerus, Arnoldus de Villa Nova, and Petrus Creſcentienſis. There are a few others, but they are too obſcure to deſerve mention.

Some part of the general zoological work of Albertus Magnus, "De Animalibus," &c. relates to inſects. Its author was biſhop of Ratiſbon, and died in 1280; but his work, which is written in the Latin tongue, and was printed at Venice, did not appear till the year 1519.

In 1549, the work of Agricola, entitled, "De Animantibus ſubterraneis," made its appearance; and in this we find one of the earlieſt ſyſtematic arrangements of inſects extant. This author reduces all inſects to three principal claſſes, namely, * thoſe which walk, ** thoſe which fly, and *** thoſe which ſwim; and under each claſs deſcribes a number of ſpecies.

About the middle of the ſame century, Edward Wotton, a doctor of medicine in London, publiſhed "De Differentiis Animalium;" a work relating, among other tribes of animals, to that of inſects, a ſcience in which its author excelled. This work is in folio, and bears date 1552; from which it muſt have appeared three years before the author's death, which happened in 1555.

The work of Rondeletius of Montpellier, "Libri de Piſcibus Marinis," publiſhed in 1555, or rather earlier, treats, as the title intimates, on fiſhes, and other aquatic animals; to which, however, it is not entirely confined; for he alſo ſpeaks of inſects, and even accompanies ſome of his deſcriptions of theſe inſects with figures cut on wood. Leſſer mentions that in the library of the Jeſuits at Ratiſbon, there is a copy of this work in two volumes; on the margins of the leaves of which are large notes, ſaid to be in the hand-writing of Geſner. Whether theſe notes have in any manner appeared before the public we know not: the circumſtance is repeated only for the purpoſe of inquiry. If Leſſer afforded any intimation of the nature of thoſe notes, we might aſcertain whether they are the ſame with the obſervations of Geſner on Rondeletius, in his "Hiſtoria Animalium," an edition of which we ſuſpect was printed ſoon after the work of Rondeletius appeared.

Conrad Geſner, eſteemed the moſt diligent inquirer into nature which his age produced, and who, in reward for his aſſiduity, obtained the title of the German Pliny, has treated ſlightly on inſects in that part of his work which relates to the nature of ſerpents, "De Serpentium Natura," &c. printed in 1587. His diſcourſe is chiefly concerning the ſcorpion tribe. Some tracts of this author appear to have been publiſhed ſo late as 1620: neither of theſe, however, are on the ſubject of entomology.

A far more voluminous work than either of the foregoing was produced by the induſtrious and learned Aldrovandus, in 1602; a folio volume of ſeveral hundred pages, with the title "De Animalibus Inſectis," and forming part of his grand work on animals. Aldrovandus has not eſcaped cenſure. In the "Amœnitates Academicæ," Forſkal conſiders him as an indefatigable compiler, celebrated for the number of his works, but who thought he had acquitted himſelf in collecting together the undigeſted obſervations of the ancients. We cannot avoid expreſſing other ſentiments; and notwithſtanding that he has fallen into many errors of his predeceſſors, this work entitles his memory to reſpect. Aldrovandus was not merely a compiler; he availed himſelf of the labours of former writers, and in this reſpect with leſs ſervility, and certainly with more candour, than many who advance this objection againſt him: for he generally refers to his authorities. Aldrovandus was profeſſor of medicine in the univerſity of Bologna, and, according to his biographers, the ſtudy of inſects was his favourite object. In this purſuit he expended large ſums of money, travelling for information, and in the employment of artiſts; as he was unfortunately, like ſome other eminent naturaliſts, himſelf deficient in the talent of drawing. During the ſpace of thirty years, he paid two hundred florins annually to a painter, ſolely occupied in the delineation of inſects for him. From the fatigue of his reſearches, this indefatigable naturaliſt was unhappily deprived of ſight in his old age.

In his claſſification of inſects, he divided all theſe animals into two primary orders, the terreſtrial and the aquatic; the firſt called favica, the other non-favica. Theſe two claſſes are ſubdivided into many orders; the characters of which are determined by the number, nature, and poſition of the wings and feet.

The repreſentations of the inſect tribes, from their inferiority of ſize, added to the general minuteneſs of their characters, are rather more rudely expreſſed in the work of Aldrovandus, than the figures of the larger animals, which theſe volumes contain. A defect of this kind is leſs excuſable, becauſe from the liberality of Aldrovandus towards his artiſt it might not be expected; and furthermore, becauſe about that period a better taſte, and a deſire for more expenſive embelliſhments in works of this deſcription, began to prevail. The graphic art, or engraving on copper, though ſcarcely emerged from infancy, was now introduced in aid of this ſcience, in preference to cuts on wood, and with no ſmall ſucceſs, as we obſerve in the works of Hoefnagle, Hollar, and others of that period, whoſe labours are well known. Thoſe embelliſhments, though greatly admired in their time, were, however, too coſtly to be introduced into works of the ordinary kind; they were confined to the more expenſive productions, and, indeed, almoſt excluſively to thoſe produced by artiſts themſelves; for we ſeldom meet with them in any work of which the artiſt is not alſo the author. The beſt book of that period in our own country, for ſuch we conſider Mouffet's "Inſectorum Theatrum," affords only cuts on wood, an inſtance ſufficiently corroborative, as this work was printed in 1634. Even for the ſpace of nearly a century after this, copperplate engravings were ſparingly introduced. The learned Liſter, in his edition of the works of Geodartius, ſo lately as 1682, laments the great expence of engravings, at the ſame time that he expreſſes his conviction that they are indiſpenſable in works of this kind. "I have taken great care of the deſigns," ſays this writer, "in tranſferring them upon copper-plates, which I dare promiſe are exquiſitely performed by the beſt of our Engliſh artiſts, which was at my expence; and the bookſellers were not willing to reimburſe me."—"And upon this occaſion I muſt needs ſay, that natural hiſtory is much injured, through the little encouragement which is given to the artiſt, whoſe noble performances can never be enough rewarded; being not only neceſſary, but the very beauty and life of this kind of learning." But, to reſume the courſe of our ſubject in hiſtoric order, the next work immediately in ſucceſſion to Aldrovandus is that of Wolfang Frenzius, publiſhed in 1612, and called "Hiſtoria Animalium Sacra," a valuable work, as containing much original obſervation. After the manner of Agricola, he diſtributes all inſects into three claſſes, which he names aërea, aquatica, and terrea et reptantia. A ſmall octavo, printed three years after, though a ſlight production, ſhould be mentioned in this place; it is a treatiſe on ants, a pamphlet of about one hundred pages, and is written in Latin; the title "De formica," &c. by Jeremiah Wilde. The work of Fabius Columna, "Aquatilium et Terreſtrium aliquot Animalium Obſervationes," printed at Rome in 1616, relates alſo, in ſome degree, to inſects; and finally, in point of precedence to Hoefnagle, we have to notice another, a work of ſome moment, that appeared ſoon after, from the pen of Archibald Simpſon: this was publiſhed in North Britain, and from the motives of the author and ſingularity of its contents claims explicit mention. From the title of this book, which is ſufficiently explanatory, it will be perceived that entomology was only a remote object in the mind of the writer. The work derives its greateſt ſhare of intereſt, in our preſent view, from being one of the firſt publications connected with the ſtudy of inſects printed in Britain. This book, which is in quarto, was printed at Edinburgh in the year 1622, and bears the following title: "Hieroglyphica Animalium terreſtrium, volatilium, natatilium, reptilium, inſectorum, vegetivorum, metallorum, lapidium, &c. quæ in Scripturis Sacris inveniuntur et pluriorum aliorum, cum eorum interpretationibus."

At length our enquiry arrives at that particular period when the painting of inſects was eſteemed ſuitable and worthy of the pencil of the moſt ſkilful artiſts of the age, the painters retained with magnificent ſalaries in the courts of princes, and in the moſt poliſhed ſtates of Europe. Under the foſtering influence of ſuch patronage, it ought not to excite ſurpriſe that ſome advancement was made in this branch of the art. For our own part, we are not impreſſed with any very high opinion of the talents evinced in depicting theſe pleaſing objects, at leaſt by ſome of the artiſts thus employed. With ſuch inducements for the exertion of genius, and with the reward and credit naturally attached to their productions, they ought certainly to have ſucceeded better. But though the arts derived no very material advancement from their attention to this ſubject, to the cauſe of ſcience their aſſiduities were productive of infinite benefit. The cultivation of exotic plants, which about that time began to be held in proper eſtimation, afforded an ample field to thoſe artiſts whoſe labours were dedicated to the taſk of pourtraying theſe pleaſing objects. Their great forte prevailed in painting flowers, and though inſects offered ſo many charms of attraction, they appear at firſt to have been only introduced occaſionally, and as ſecondary objects, to their pictures. Theſe embelliſhments were attended with ſucceſs in proportion to their fidelity, force, and truth. In a ſtate of nature theſe lively creatures are conſtantly ſeen ſporting about the unfolding bloſſoms of the vegetable creation in ſearch of their nectareous ſuſtenance, and their introduction could not fail to infuſe a ſpirit of ideal animation into their beſt performances. Hence it ſeems, that inſects were afterwards repreſented in their compoſitions with a leſs ſparing hand; and, in the courſe of time, became with many artiſts the principal, inſtead of ſecondary object of imitation. Thus alſo, from caſual obſervers, thoſe artiſts were progreſſively led to a more intimate acquaintance with theſe creatures, and to an inquiry into their hiſtory, the novelty of which may be perceived to have amply gratified their curioſity, and rewarded their application. Their example fortunately inſpired a congenial taſte among their patrons, and hence, in the ſpace of a few years, a new and more propitious era ſeemed to dawn upon the ſcience of inſects. The ſtudy was by this means promoted, and rendered an object of attention among the higher orders connected with the moſt enlightened courts of Europe; as for inſtance, that of France, the imperial court of Germany, and thoſe of the princes of the empire.

An obſervation of the celebrated Juſſieu in the beginning of the laſt century is altogether applicable to this inveſtigation. "The arts and ſciences," ſays this writer, "owe their perfection to circumſtances which may appear the effect of chance," and the truth of this remark is completely verified in this particular inſtance; for, it muſt be recollected that the art of embroidery, a mechanical proceſs, and which in our days is ſuperſeded by the more dignified production of the pencil, is that which called forth the talents of the painter to the delineation of natural objects in the age adverted to. It was to the improvement of embroidery that his merits were at firſt ſubſervient; or at all events to a peculiar train of circumſtances ariſing originally from this cauſe, that we are to aſcribe the progreſs made in this branch of the profeſſion, from the cloſe of the ſixteenth till the middle of the ſucceeding century. About the reign of Henry IV. and Lewis XIII. of France, embroidery was in the zenith of faſhion, for the decoration of magnificent furniture, and drawings of the moſt beautiful plants were made expreſsly for the embroiderer's imitation. The obligation which botany lies under to this cauſe is well known, and that of entomology during the ſame period, if attentively conſidered, will be found no leſs conſpicuous.

The painters eminent for their abilities in this line, were Hoefnagle, Robert, Aubriet, De Bry, Vallet, and Robin. There were others to whom we ſhall advert more particularly afterwards. In order to demonſtrate the benefit which botany derived from the labours of ſuch artiſts, it need only be mentioned, that the celebrated Tournefort founded and arranged his ſyſtem of plants upon the drawings made by Robert and Aubriet for the royal library of France. The other artiſts alluded to were ſtill more converſant with the ſcience of inſects than the former, and the labours of their pen have contributed, in uniſon with their pencil, to promote this ſpecies of knowledge. Some eſpecially were very ſucceſsful in this reſpect.

Merian, Admiral, Schwertz, and Goedart, and alſo our own countryman Albin, were among the number of thoſe moſt eminent for their acquaintance with the hiſtory of inſects; and, were this liſt to be augmented with the names of other artiſts of ſomewhat later date, who have likewiſe diſtinguiſhed themſelves in the ſame manner, the reſult would teſtify that entomology, like many other branches of natural hiſtory, is greatly indebted for its advancement to this claſs of authors. It is from the works of the artiſt, or of thoſe who by their application have rendered themſelves competent to delineate the objects they deſcribe, that the moſt valuable information has been obtained. The works of Röſel will ſufficiently teſtify the truth of this obſervation, but were any other confirmation neceſſary, we would advert to Lyonet who, though not an artiſt by profeſſion, felt proudly conſcious of his ſuperiority as a naturaliſt, becauſe from perſeverance he had acquired the talents of an artiſt. Are they not the imitative labours of this claſs that furniſh ample materials for the productions of thoſe who are mere deſcribers: writers, who oftentimes like hornets enter the hives of induſtry, and plunder without moleſtation?

The work of Hoefnagle, a thin volume in 4to. was publiſhed in 1630, under the title of "Diverſæ Inſectorum volatilium icones ad vivum depictæ per D. J. Hoefnagle, typiſque mandatæ a Nicolao Joannis Viſcher."

The plates altogether contain figures to the amount of three hundred and twenty-ſix. The execution of theſe acquired the artiſt no ſmall ſhare of celebrity, yet it muſt be acknowledged that they are not invariably deſerving of approbation; ſome at leaſt are very indifferent. Hoefnagle does not adopt any particular mode of arrangement, and he contented himſelf with repreſenting the inſects in the ſtates in which chance preſented them, without always following them through their progreſſive changes.

Only four years elapſed after this volume of Hoefnagle's plates were brought forward, before another production of infinitely greater conſequence as a work of ſcience appeared in our own capital, namely, the entomological work of Thomas Moufet. This, as it profeſſes to be, is an improvement on the work of Dr. Wotton, begun in the year 1550, about five years before his death: it was continued by Conrad Geſner, was afterwards enriched, as it is expreſſed by Thomas Penny, and at length aſſumed the improved form in which it was publiſhed in 1634, from the hands of Moufet. This laſt mentioned editor reviſed the order of its arrangement, corrected and enlarged the deſcriptive matter, and embelliſhed its pages with nearly five hundred wood-cuts, the greater portion of which, though rudely executed, are not deſtitute of merit. The work is intitled "Inſectorum ſive minimorum animalium theatrum: olim ab Edoardo Wottono, Conrado Geſnero, Thomaque Pennio inchoatum; tandem Tho. Moufet Londinâtis operâ ſumptibuſque; maximis concinnatum auctum, perfectum: et ad vivum expreſſis iconibus ſupra quingentis illuſtratum." This author divides his work into two parts, the firſt containing twenty-nine chapters, the latter forty-two, under which he reſpectively deſcribes the ſeveral tribes of inſects, known among the early writers by the names of veſpis, muſcis, papilionibus, cicindela, blattis, cantharide, bupreſti, meloe, &c. terms familiarized to the Linnæan ſcholar, but which are not always applied by Linnæus to the particular tribes of inſects, deſignated by theſe names in the work of Moufet and his predeceſſors: a fault we truſt to ſee one day amended.

Hollar gained conſiderable reputation by his iconical work, "Muſcarum, Scarabeorum Vermiumque variæ figuræ et formæ omnes primo ad vivum coloribus depictæ et ex collectione Arundeliana," &c. publiſhed at Antwerp in the year 1646. The drawings were preſerved in the Arundel cabinet; the plates are etchings in the uſual ſtyle of its author.

About an hundred and fifty pages of the extenſive work of J. Jonſton, "Hiſtoria Naturalis." is devoted to the ſubject of inſects, which tribes he diſtributes into four books, the firſt of which treats on terreſtrial inſects provided with legs and wings, the ſecond of terreſtrial inſects which have feet and no wings, the third of the terreſtrial apodal order, and the fourth of aquatic inſects. Theſe are illuſtrated by twenty-eight plates engraved on copper by the author, who was doctor in medicine.

Few authors are condemned with more critical ſeverity than Jonſton; his work is certainly a compilation, and as it has been ſtated, his materials are moſtly taken from the works of Aldrovandus, Moufet, and others. Forſkal denominates him a perſevering compiler, and at the ſame time obſerves that he has not added a ſingle remark to what was before diſcovered. Theſe obſervations appear in the "Amœnitates Academicæ," in which there is alſo another paper by Bladh, where we find the ſame ſentiments repeated. The opinion thus expreſſed is known to have the ſanction of Linnæus. This deficiency in the arts, to which he aſpired, is warmly cenſured by Lyonet, who declares his butterflies to be of unſufferable deformity, and in form, or outline, to be conſtantly alike in all the figures. As an artiſt, nevertheleſs, he had his admirers: if we can place any reliance on the truth of his biographers, he was not deſtitute of ability. Moncoyns ſays, he ſaw in the hand of Mr. Platern of Baſil a ſet of drawings executed by him with tolerable accuracy. And Leſſer himſelf owns that many years ago he was ſhewn others very prettily painted by him on blue paper, in the poſſeſſion of a nobleman belonging to the houſehold of one of the kings of Poland.

The work of Jonſton, which is in folio, and dated 1657, was publiſhed at Amſterdam. In the year following, we meet with an Engliſh tranſlation of Moufet's work, printed by Topſal, chaplain of St. Botolph's, in London. Nearly about the ſame time the work of Goedart, a Flemiſh painter, made its appearance in Holland in the language of that country. The laſt mentioned production deſerves more explicit mention, for we think its merits have never been very candidly eſtimated,

eſtimated. The engravings are deſcribed as of miſerable execution, and the figures ſo indifferent in point of reſemblance to the objects intended, that they could only in particular inſtances be underſtood; and again, on the contrary, the details are repreſented as ſo defective, that unleſs accompanied by his valuable plates, they would be uſeleſs. So much is advanced by his various annotators, and yet with all theſe imperfections, thoſe individuals have condeſcended at different times to favour the world with tranſlations of his work, originally written in Dutch, into the Latin, French, German, and Engliſh; and with various editions of the plates alſo. The truth is, that Goedart was a painter; the mere deſcribers, from unworthy motives, were offended that he ſhould preſume to write, while they profeſſed to be enraptured with his talents in the arts; and the artiſts denied him praiſe becauſe they conſidered him as a naturaliſt, not a painter. Were this work of Goedart the production of our days, it would be undeſerving of comment; but let us conſider the period in which it was produced, and abating our expectation of excellence in thoſe times either in the accuracy of obſervation, the hiſtory of inſects, the ſtyle of language, or correctneſs of deſign; and we muſt acknowledge it in every reſpect as a valuable performance. The beſt of his annotators, even the ingenious Liſter, to whom the original work was certainly under moſt obligation, has committed ſeveral errors in endeavouring to correct him.

For the ſpace of about twenty years Goedart devoted great attention to the ſtudy of inſects. He followed them through their progreſſive changes with great preciſion: this renders his book more extenſively acceptable, and his figures, which have never been ſurpaſſed by his predeceſſors, are for the moſt part ſo far correct as to be underſtood. The Dutch edition of Goedart's work being ſoon ſold off, the firſt volume of a Latin tranſlation, by Dr. Mey, miniſter of Middleburgh, was brought forward under the title of “Metamorphoſes et Hiſtoria Naturalis Inſectorum,” in the year 1662; and a ſecond volume alſo, in the ſame language, tranſlated by M. P. Veezaerdt, miniſter in Zealand, who added thereto ſome remarks of his own. Another tranſlation of this latter part was afterwards publiſhed by Dr. Mey, with a farther addition of notes. Liſter allows thoſe annotators no credit for their labours; Goedart, he obſerves, left his writings in Dutch; “His Latin interpreters,” ſays he, “have added comments indeed, but were men wholly ignorant in natural hiſtory, and their comments are mere rhapſodies, and altogether impertinent to the explication of any one hiſtory of Goedartius.” Dr. Liſter re-arranged and corrected this work, and added at the ſame time many curious obſervations.

A hiſtory of animals and minerals, in the courſe of which the ſubject of inſects is noticed at ſome length, appeared in London in 1661, under the title of “Πανζωορυκτολογια.”

The invention of the microſcope opened to the curious a new opportunity of penetrating into the myſteries of nature, and diſcriminating with accuracy the moſt delicate organs of the minor tribes of animals, which from their minuteneſs had evaded obſervation before, and among theſe the inſect race alone conſtituted ſuch a vaſt proportion, that we may attribute to this cauſe that ſpirit and perſeverance with which the ſtudy of theſe minute bodies was purſued about this particular period, and for the ſpace of ſome years after. The era of this invention is aſcribed to the year 1680, and although this does not appear to be ſtrictly accurate, ſince an apparatus correſponding with it was in uſe at the earlier date of 1618, and that glaſſes poſſeſſing the power of enlarging the appearance of objects very conſiderably were known among the ancients; yet, upon the whole, it may be concluded, that what is now underſtood by the microſcopical inſtrument, received ſo much improvement about the time firſt mentioned, that, in qualified terms, we muſt date its invention from that period. The diſcoveries made by the aſſiſtance of the microſcope within a few years after this time renders it a memorable epoch in the ſcience of natural hiſtory, and ſo far as relates to inſects, it is probably owing to the introduction of this valuable inſtrument into general uſe, that the names of Hooke, Power, Pierre Borel, Bonomo, Antoine Van Leuwenhöek, Joblot, and Hartſoeker (the latter of whom detected the circulation of the fluids in inſects); and many other inquiſitive individuals appear in the liſt of entomological phyſiologiſts, or anatomiſts.

The work of Power is in quarto, and was printed in 1664; this relates ſlightly to inſects as objects of microſcopical inveſtigation. Hooke's “Micrographia” appeared the year after, and treats of inſects in the ſame view. In the memoirs of the French Academy of Sciences in Paris, for 1666, there are ſome entomological obſervations by Mignot de la Voye; and in the fifth volume of the Philoſophical Tranſactions a paper relating to “inſects lodging themſelves in willows,” by King and Willughby. But the letters of Liſter, which alſo appeared about the ſame time, or within the courſe of five or ſix years after, are ſtill more valuable; among theſe are “letters concerning a fly that is viviparous, and concerning an inſect feeding on henbain.” “A conſiderable accompt touching vegetable excreſcencies;” “Letters about muſk-ſcented inſects, vegetable excreſcencies, and ichneumon-worms;” “A Letter containing the projection of the threads of Spiders, and Bees breeding in caſes made of leaves, a viviparous fly, &c.”

A ſmall number of the inſects indigenous to Britain is deſcribed by Chriſtopher Merret, in his “Pinax rerum naturalium Britannicarum,” &c. publiſhed at London in the year 1667.

An account of the tarantula engaged the pen of Wolferdas Sanguerdius (a medical profeſſor) about the middle of this century; his work, entitled “Tractatus phyſicus de Tarantula,” appeared in the year 1668; it is a ſmall duodecimo of ſeventy pages, and was printed at Lyons. The general work of an Engliſh entomologiſt, Charleton, was the ſame year publiſhed in London, under the title of “Onomaſticon Zoicon, pluriorumque animalium differentias et nomina propria pluribus linguis exponens,” in which we have a ſyſtematic arrangement of inſects after the manner of Aldrovandus. There is a mantiſſa of this work printed in folio in Oxford, in 1677.

Another work on entomology, a treatiſe profeſſedly elementary, was publiſhed at Leipſic, the year after the firſt part of Charleton's work appeared. It is in quarto, and is entitled “Diſſertatio de Inſectis in Genere,” &c. Jacob Wolff, profeſſor of medicine at Jena, was the author.

Redi's “Experimenta circa Generationem Inſectorum,” for the time in which it appears (1671), is an intereſting little book. Its author combats the doctrine of equivocal generation, maintained among the ancient philoſophers; and deduces its fallacy from a variety of experiments and obſervations of great critical accuracy; in the courſe of which he demonſtrates that every living creature is produced from an egg. The ſame work contains about thirty figures of the lice peculiar to particular birds, ſuch as the pigeon, ſwan, pie, heron, &c. The ſame writer alſo publiſhed his work on the generation of inſects in his native language, “Eſperienze in torno alla Generazione degl' Inſetti,” 1688. There are ſeveral uſeful tracts by Redi on natural hiſtory; but the above-mentioned is that which principally relates to entomology.

Another curious work, "Experienze intorno alla Generazione dellé Zanzare," a ſmall tract of about twenty pages, and embelliſhed with one plate, was publiſhed in 1679. It is entirely confined, as the title implies, to the common gnat (culex pipiens), and is written by F. P. Sangallo.

A writer, whoſe celebrity for his anatomical knowledge of inſects can never be eraſed, while the ſcience itſelf continues to be reſpected, is the next in order for our conſideration: this is the indefatigable Swammerdam. One of the moſt important works of this acute obſerver of nature, his general hiſtory of inſects, bears date 1669. We allude to the firſt edition printed at Utrecht, in the Dutch language, under a Latin title, "Hiſtoria Inſectorum Generalis; ofte algemeenver handeling van de bloedeloose Dierkens." Of this work it has been well obſerved by a German critic, that it has no other fault than that of being written in a language not generally known. The work, in this original ſtate, is in the quarto form, compriſing rather more than two hundred pages, and is illuſtrated by figures contained in thirteen copper-plate engravings.

Some years paſſed away before the excellence of this work, the admiration of the learned in later times, was in any manner acknowledged; and the fate of Swammerdam, a man who, in the generoſity of his mind, had exhauſted the greater portion of his life in the completion of a work, ſo wiſely calculated to enlarge the boundaries of human knowledge, affords another and very ſtriking inſtance of genuine worth neglected:—another example of that culpable ſpirit of ingratitude which living merit ſo rarely fails to experience, in reward for the moſt ſplendid ſervices their talents confer upon an illiberal world!—Chilling thought! that gloomy reflection which oftentimes ſuppreſſes the bright, the enviable, but too fatal exertions of genius, and ſhrouds the mind in apathy and indifference! No ſooner was the death of Swammerdam announced, than his merits were diſcovered; and an anonymous tranſlator rendered his book into French. Almoſt immediately after, another appeared in Latin; and after ſome time, another in Engliſh: all which contributed, but too late, to the author's fame. He died in 1680. The firſt French tranſlation is dated 1682, and, like the original, is in quarto, and embelliſhed with plates. The Latin tranſlation correſponds with the two preceding, except that Hennius, in a ſecond edition of the Latin copies, enlarged one chapter which treats on the analogy between inſects and other animals and plants. The firſt Latin edition, "Hiſtoria Generalis Inſectorum, Latinam fecit H. C. Henninus," was printed at Lyons in 1685; the augmented copy in 1693, at Utrecht. The Engliſh tranſlation is by Thomas Flloyd, and is printed with the edition of the "Biblia Naturæ," in our own language, publiſhed in London, in 1758.

The latter work of Swammerdam was introduced to the public under very extraordinary circumſtances. Such was the ill ſucceſs of his former writings, that the "Biblia Naturæ," after being prepared in manuſcript for preſs, was left unpubliſhed. No bookſeller would venture to print it at his own riſk; and the means of Swammerdam were inadequate to its production. At the death of the writer, M. Thevenot, his friend, became poſſeſſed of his papers, and with the copy of this among the reſt. With him they remained ſome time, and then paſſed into the hands of Du Verney, an able anatomiſt, who enriched his own cabinet with the manuſcript of this work. With him it lay buried, till the zealous and illuſtrious Boerhaave purchaſed them; and he was no ſooner poſſeſſed of it than he haſtened to communicate this treaſure to the world, and it was accordingly put to preſs in 1736. He included in this publication the former works of the author, and publiſhed the whole under the title of "Biblia Naturæ, ſive Hiſtoria Inſectorum Belgice, cum Verſione Latina H. D. Gaubii, et Vita Auctoris per H. Boerhaave." This work is in folio: the firſt volume, conſiſting of five hundred and fifty pages, appeared in 1737; and the ſecond volume, of much greater bulk, and with many plates, in the year following.

The ſyſtem propoſed by the author of this work, for the arrangement of inſects, differs ſo materially from that given by any preceding author, that we cannot avoid conſidering it immediately relevant to our preſent ſubject. The general or principal claſſes into which inſects are divided in his ſyſtem amount to four; and the characters of theſe relate to the metamorphoſes the inſects undergo, rather than to their appearance in the perfect ſtate, the firſt claſs excepted.

The firſt of theſe four claſſes comprehends thoſe ſubject to no change of form, but which quit the egg in the ſame ſtate and appearance they are to retain during life. This claſs includes ſpiders, oniſci, &c.; and muſt be therefore underſtood as admitting of an increaſe in bulk, though not undergoing any change in form.

The ſecond claſs includes thoſe which, after leaving the egg, appear under the form of an inſect without wings, the other members formed; in which ſtate it eats and grows, till, having paſſed into the ſecond or nymph ſtate, it iſſues from thence with wings, and is in a condition capable of propagating its kind. The locuſts and dragon-flies are included by its author in this claſs.

In the third claſs, the animal, after having iſſued from the egg, where it remained in a diſguiſed ſtate, and without food, appears under that of an inſect which eats and grows, while the members of the animal into which it is to be converted are formed under the ſkin, and which it at laſt quits, and becomes a nymph or chryſalis (of the dormant kind). This claſs includes moths and butterflies, &c.

The fourth claſs conſiſts of thoſe which, having arrived at the nymph ſtate, like thoſe before mentioned, do not diveſt themſelves of the ſkin, in order to enter into that ſtate, but aſſume the form of the nymph under its ſkin, where it continues ſhut up, till, quitting two ſkins at once, it comes forth in the perfect ſtate. The inſects of this claſs, according to its writer, are exemplified in the ichneumon.

There are ſome few ſmall tracts publiſhed by this author during his life, neither of which is of material conſequence, except that on the natural hiſtory and anatomy of the ephemera horaria, "Ephemeri Vita, of afbeeldingh van 's menſchen leven, vertoont in de Hiſtorie van het uligent ende een-daghlevent Haft of Oever-aas," a work in octavo, printed at Amſterdam in 1675. Immediately after the author's deceaſe, namely in 1681, there were no leſs than two tranſlations of this work; one in quarto, in Engliſh, and printed at London; the other by M. Thevenot, at Paris.

No work materially important on the ſubject of entomology appeared after the firſt edition of the work of Swammerdam, till the years 1678 and 1679, in which Liſter publiſhed his valuable hiſtory of Engliſh ſpiders, and Madame Merian her extenſive work on the metamorphoſes of lepidopterous inſects. In the interval between there were ſeveral publications, which, though not of the moſt valuable kind, are ſufficiently intereſting to claim remark. Claude Perrault, one of the ableſt writers on exotic inſects of his age, and author of ſeveral papers in the Memoirs of the French Academy, produced a work in folio at Paris, in 1671, which treats on inſects, under the title of "Memoirs pour ſervir à l'Hiſtoire naturelle des Animaux;" and to this ſome additions were made in 1676. The work of Ferrand of Naples alſo relates to inſects, among other animals; and this appeared in 1672. The year after Frenzelio ſubmitted his "Inſecta novifolii cum nive delapſa;" and at Franckfort on the Main, D. W. Mollerus brought forward his "Meditatio de Inſectis quibuſdam Hungaricis prodigioſis anno proxime præterito, ex aëre una cum nive in agros delapſis," an uſeful treatiſe of 120 pages, with two wood cuts. In 1675, George Berelio printed at Upſal his elementary tract, περὶ τῶν ἐντόμων. The ſame year alſo, Samuel Bochart publiſhed his "Hierozoicon, ſive bipartitum Opus de Animalibus ſanctæ Scripturæ." Müller, in 1676, gave an orationary paper on the tarantula ſpider, "Diſſertatio de Tarantula;" and Hermannus Grube, a curious little octavo volume on the ſame ſubject, "De Tarantula, et vi Muſices in ejus curatione, conjecturæ phyſico-medicæ.

Dr. Liſter diſtinguiſhed himſelf in the annals of entomology about this period. Previous to the publication of his "Hiſtoria Animalium Angliæ Tractatus de Araneis," ſeveral papers by this author appeared in the Philoſophical Tranſactions, the principal of which relate to this tribe of creatures; ſuch as his obſervations on the darting of ſpiders, in the fourth and fifth volume; his paper entitled, "Some Inquiries concerning Spiders;" and his "Tabulæ compendiariæ Araneorum Angliæ," in the ſixth volume. Liſter's work on ſpiders, before mentioned, relates chiefly to thoſe indigenous in England, and are arranged and deſignated by conciſe ſpecific characters with much ſcience, correſponding with that adopted afterwards by Linnæus. This is in quarto, and was printed at London in 1678; the appendix, "De Araneis addenda et emendanda," &c. in 1681. There is a tranſlation of this work in the German language, by F. W. H. Martini, printed in 1778.

We are in poſſeſſion of the firſt tranſlation of the works of Goedart by Liſter, a book printed at York in 1682, under the following title, "Johannes Godartius of inſects, done into Engliſh and methodized, with the addition of notes; the figures etched upon copper by Mr. F. Pl." The name of Liſter does not appear; but the initials at the cloſe of the addreſs to the reader are M. L.; and in our copy, the letter L is rendered Liſter, in the hand-writing of an entomological collector well known in the earlier part of the laſt century. The latter circumſtance, though not apparently of much moment, is related becauſe the fact might admit of doubt, the work being anonymous, and perhaps forgotten. The impreſſion conſiſted, as the preface acquaints us, but of 150 copies, which were intended only for the curious; and in the courſe of nearly 130 years, it may be naturally concluded many of theſe muſt have been loſt. The notes in this book are very copious. In 1685, an edition of Goedart by Liſter appeared in Latin. The tranſlator in this, as in the former work, diſtributes the materials of Goedart's performances into a new form of arrangement, the merits of which are too obvious not to be conſidered as an improvement on the original production. He divides them altogether into ten ſections; for they are not ſtrictly, in every inſtance, what we might denominate *orders;* in ſome they certainly are. The firſt, ſecond, and third ſections are of the lepidoptera kind, and very clearly diſcriminate the papiliones from the moth tribe.

The 1ſt includes thoſe with erect wings; theſe are the butterflies which fly by day, and the chryſalids of which are angular.

2d. Moths with the wings placed horizontally, and which proceed from the caterpillars called geometræ by Goedart, becauſe of their gait, which is like that of a meaſurer of land.

3d. Moths with deflected wings, or thoſe with hanging wings ſitting cloſer to the body than in either of the two preceding.

4th. Libellulæ, or dragon flies.

5th. Bees.

6th. Beetles.

7th. Graſshoppers.

8th. Dipterous flies.

9th. Millepedes.

10th. Spiders.

Goedart ſpent forty years of his life, as he expreſſes it, "daily converſing with inſects;" and from the courſe of his obſervations, it is manifeſt he was well acquainted with his ſubject. Liſter is nevertheleſs unwilling to concede this point: he neither allows him credit as a naturaliſt or a writer, at the ſame time that he extols his excellent ſkill in limning. Theſe opinions are delivered in a ſtyle of affected ſuperiority over his author, neither becoming, nor ſtrictly true; and ſeem to be dictated ſo nearly in the ſpirit of ſome more modern critics, that one cannot avoid ſmiling at the compariſon. "Goedart," ſays he, "after forty years attention, ſeems to have made little advancement in his ſkill in the nature of inſects: he ſeems rather to have diverted himſelf with them, than to have given himſelf any trouble to underſtand them; and yet after all, you will find him every where very juſt, and true in his obſervations, but in many places very ſhort, and hardly intelligible." Our Engliſh annotator gained no reputation on the continent for theſe general remarks, although the merit of his notes relating to the metamorphoſes of inſects was acknowledged; the works of Goedart ſtill maintained their credit.

Maria Sybilla Merian, vel Gräffinn, the wife of John Andrew Gräffinn, was a native of Franckfort on the Main, and early in life imbibed a taſte for the ſtudy of inſects, from being occupied at times in painting theſe pleaſing objects as embelliſhments to her flower-pieces. The taſk of painting inſects was performed by this fair artiſt with no very faſtidious ſhare of accuracy. In point of drawing ſhe rarely excels; and her productions, though ſplendid memorials of her talents, and the great encouragement ſhe obtained, are marked by a peculiar exuberance of ſtyle incompatible with any faithful reſemblance of nature. Her firſt work was publiſhed in 1679, and relates to European inſects, chiefly thoſe of the lepidopterous order, with their changes, and is entitled "Der Raupen wunderbare verwandeleng, und ſonderbare blumen-nahrung:" another part appeared in 1683. Theſe were publiſhed at Nuremberg. In 1718, another work by the ſame authoreſs was publiſhed at Amſterdam, called "Erucarum ortus, Alimentum et Paradoxa Metamorphoſis." After this we have an hiſtory of the European inſects, rendered from the Dutch text of Madame Merian into French, with an augmentation of the deſcription of the plants by J. Marret, a work printed in folio at Amſterdam, in 1730. But the beſt of all her publications came out at the Hague in 1726, in a folio of ſuperior ſize, with the title "De Generatione et Metamorphoſibus Inſectorum Surinamenſium," &c.; the materials for which were collected by herſelf, or under her own inſpection in Surinam. This lady had made a voyage from Holland to South America in 1699, for the avowed purpoſe of forming a collection of natural curioſities for this work, and was occupied at Surinam during the ſpace of two years in taking drawings and deſcriptions of various objects for this purpoſe. This work is not entirely devoted to entomology, as, beſides inſects, it contains a miſcellaneous ſineous aſſemblage of toads, lizards, ſerpents, and other reptiles, and likewiſe a pretty extenſive number of plants.

In the Philoſophical Tranſactions are to be found ſome obſervations concerning inſects, made in Virginia in 1680, with remarks by J. Petiver. Hoppio, in 1682, publiſhed at Jena a diſſertation on the gryllus migratorius. Two years after, another ſmall tract appeared alſo at Jena, a paper on ants, "Reſpublica Formicarum," by A. Schmidt.

The fifteenth volume of the Philoſophical Tranſactions affords an account of the "Connough-worm," by Wm. Molyneux, a paper afterwards tranſlated into Latin, and inſerted in one of the continental journals under the title of "Obſervatio de Inſecto Hibernico vocato Connough-worm." Some few entomological obſervations of a miſcellaneous nature, extracted from the manuſcript hiſtory of Pembrokeſhire by George Owen of Henllys, lord of Kemmes, occurs in the eighteenth volume of the ſame Tranſactions. The original MS. of this hiſtory we have ſeen in the Britiſh Muſeum. Beſides the above, the Tranſactions about the ſame time contain ſeveral intereſting papers relative to inſects; as Allen's account of the gall-bee, and the death-watch, in vol. 20. "A Letter concerning an Inſect commonly called the Death-watch," vol. 22. which reſpects both ptinus pulſator, and hemerobius pulſatorius, written by William Durham; and alſo a ſupplement to an account of pediculus pulſatorius or death-watch, in vol. 24.

But, in point of priority, we ought previouſly to have mentioned the earlier works of Leeuwenhoek, a writer whoſe aſtoniſhing aſſiduity, aided by means of powerful microſcopes, has contributed more than any other man, except Swammerdam, to diſcloſe to our view the wonders of the inviſible creation, in the ſphere of which the minima of the inſect race become of the firſt conſideration. One of the firſt papers of this intelligent obſerver appears in the eighth volume of the Philoſophical Tranſactions, and is entitled "A Specimen of ſome Obſervations made by a Microſcope contrived by M. Leeuwenhoek." His communications to the world after this became numerous; and, as the object of his purſuit was of a nature to ſtimulate a ſpirit of inveſtigation, it could ſcarcely at the ſame time fail to excite controverſy. It led, therefore, to the production of many papers by different writers, all which tended, in ſome degree, to the further elucidation of the ſubject. As theſe, however, are only in part connected with entomology, it would be fruitleſs for us to follow, through the varied branches of diſcuſſion, and to ſelect thoſe particular paſſages which relate to our preſent inquiry; for theſe we refer the curious reader to Tranſactions of the Royal Society, from the eighth to the thirty-ſecond volume; and to various publications printed at Leyden and Delft in 1686, 1693, 1697, 1704, &c. Among the principal works of Leeuwenhoek, are "Anatomia, ſeu interiora rerum, cum animatarum tum inanimatarum (ſic) ope et beneficio exquiſitiſſimorum microſcopiorum detecta," 1687; "Arcana naturæ detecta," 1695; and "Opera omnia," 1722; an Engliſh edition of the ſelect works of this author was undertaken in London in 1798.

Geyerus, in 1687, was author of a medical tract in quarto printed at Leipſic and Frankfort, called "Tractatus phyſico-medicus de cantharidibus," and which, as the title implies, relates to the medicinal properties of thoſe well known inſects, the cantharides. Bononius, in the ſame year, publiſhed a letter at Florence, in which he enters on an extenſive detail of his obſervations on many inſects, with the microſcope, and lays claim to ſeveral diſcoveries. And J. F. Griendel, Von Ach, canon of the order of the Holy Ghoſt, produced his "Micrographia nova" at Nuremberg alſo at this time; a quarto volume of ſixty-four pages, ſome of which are dedicated to his microſcopical obſervations on inſects.

The work of Stephen Blankaart of Amſterdam made its appearance in 1688. Its author, a Dutch phyſician, was an aſſiduous collector, and in this inſtance produced a work, the plates of which have been as much admired for the beauty of their execution as the work in other reſpects has been condemned. Friſch, and after him Lyonet, conſider it as an indifferent production. It relates chiefly to the larva of different inſects, as the caterpillars of ſeventeen lepidopterous inſects, twelve maggots of flies, and a few other inſects, amounting altogether to forty-ſeven ſubjects. The title is, "Schou Berg der Rupſen, Wormer, Maden en vliegende Dierkens daar uit voort-kommende." The paper of John de Muralto, and alſo that of C. Mentzelius, relating to different inſects, appeared about this period; and the work of John Cyprien, "Hiſtoriæ Animalium," was alſo printed in 1688; it was publiſhed at Frankfort, and relates to inſects among other animals. A ſmall tract, an orationary paper of eight pages, with a ſingle plate, entitled "Chymica Formicarum," is from the pen of profeſſor Sperling in 1689. Koenig's "Regnum Animale," &c. printed in 1690; Bilberg's "Locuſtæ," a diſſertation, printed at Upſal in 1690; and "Hiſtoria Vermium" by Jungius, printed at Hamburgh in 1691, are all intereſting, and a paper by Sedileau, publiſhed in 1692 in the Memoirs of the French Academy, is rather curious; this latter is denominated "Obſervations ſur l'origine d'un eſpece de Papillon," and the inſect treated upon is bombyx pavonia γ major. The prodigious ravages occaſioned by the ſwarms of locuſts which, in the month of Auguſt 1693, over-ran Germany, and extended their ſcattered legions throughout the reſt of Europe, even to the borders of the moſt northern countries, were an event of ſuch an afflicting nature, that it could not fail to engage the obſervations of many writers, in the number of which we meet with the names of ſome naturaliſts of ability, whoſe diſſertations on this occaſion are acceptable. Treunero, Hebenſtreit, Woollenhaupt, Crellius, Kirkmajor, and Ludolfus, wrote at this time on the ſubject, relating the particulars of their appearance, the devaſtations committed, and the moſt effectual means of deſtroying them. The ſpecies was the common migratory kind, gryllus migratorius. Theſe tracts were generally trifling in point of ſize, that of Hebenſtreit, however, "De Locuſtis immenſo agmine aërum noſtrum implentibus, et quid portendere putentur," conſiſts of 65 pages and one plate, and that of Ludolphus, entitled "Diſſertatio de Locuſtis, anno præterito immenſa copia in Germania viſis, cum diatriba, qua ſententia autoris de שלוים defenditur," is a folio of eighty-eight pages, and embelliſhed with figures.

Albino publiſhed a ſmall tract on the cantharides in 1694, and the following year "Jacobi Petiveri Muſæum," a ſmall octavo, was publiſhed in London. Theſe, with the elementary work of Jacobæus, "Diſſertatio de vermibus et inſectis," and that of Baglivus, printed at Rome in 1696, on the effects of the bite of the tarantula, and a paper of Homberg on the libellula virgo in the Memoirs of the French Academy for 1699, appear to be the only publications deſerving of mention till the commencement of the eighteenth century.

The earlier part of the eighteenth century forms an era in which the ſcience of entomology was cultivated with the happieſt ſucceſs. It is with ſome pride alſo, we obſerve, that even in the comparatively improved ſtate to which the ſcience had then attained, it derived no inconſiderable

ſiderable advancement through the labours of our own countrymen. The works of Ray and Liſter, with thoſe of Petiver in England, and thoſe of the indefatigable Reaumur in France, contributed eſſentially to this purpoſe, and to the preſent day ſerve in ſome meaſure to maintain the reputation of ſcience. The works of thoſe authors were ſucceeded within the firſt fifty or ſixty years by other works of high conſideration, as will be found hereafter. In the interval of time that elapſed between the publications of thoſe more extenſive and valuable works, others of leſs importance, but which yet deſerve mention, made their appearance; as, for inſtance, in 1701 the ſmall, but curious diſſertation of Heucherus, called "Araneum homini pernicioſum et ſalutarem;" the little treatiſe by Vallerio of Upſal on the tarantula, publiſhed the year after; the entomological part of the work of G. B. Rumphius, in 1705, and that of Ruiſch, "Theatrum univerſale omnium animalium," publiſhed in 1710—1718. Henninger produced a ſmall medical tract relating to millepedes, in 1711. Wedelio on an old ſubject, the utility of the cantharides, in the Materia Medica, at Jena, in 1717; and Whitaker, the year following, on the ſame inſect: the remarks of J. Pontedera, "De Cicada," &c. annexed to his botanical work; and two tracts by Laurentius Roberg, medical profeſſor at Upſal, "Formicarum Natura," and "Libella inſecta."

It was in the year 1702 that Petiver produced the firſt decade of his "Gazophylacium naturæ et artis," the publication of which was carried on progreſſively till for about ten years after, during which period the work was extended to ten decades, each containing plates excluſive of the "claſſical and topical catalogues." This work relates to inſects among other animals, plants, and foſſils. About twelve months before the author's death, which happened in 1718, there was, however, another work printed by him under the title of "Papilionum Britanniæ Icones," &c. and which, as the title expreſſes, relates to the Engliſh butterflies, and is entirely confined to entomology.

A work by Ray, appropriated to this branch of ſcience, was publiſhed in 1705, under the title of "Methodus Inſectorum, ſeu in methodum aliqualem digeſta," and which can be conſidered only as the introduction or prelude to the great work, "Hiſtoria Inſectorum," which the world received in 1710, through the care of Dr. Derham; for Ray did not live to ſee it publiſhed.

This celebrated naturaliſt divides all inſects into two principal claſſes, thoſe which undergo transformation in their form, and ſuch as do not paſs through any tranformation after being produced in the firſt inſtance. Each of the two principal claſſes are ſub-divided into ſeveral orders, which are variouſly characterized, as by the number of the feet, or by being deſtitute of thoſe limbs. Some are determined by the habitation of the inſects; by the ſize or conformation of various parts of the body; by the odour they emit; the form of the caterpillars, and various other peculiarities. This arrangement is in part conformable with the writer preceding; the intranſmutablia, or order of thoſe which do not paſs through any metamorphoſes, is due to Willughby; and the three orders of changeable inſects correſpond with the 12th, 13th, and 14th orders of Swammerdam's claſſification. His claſs of changeable inſects is divided into ſeveral families, as vaginipennes, from having the wings covered with a ſheath, papiliones, quadripennes, bipennes, &c. There is an appendix to this work by Liſter, "Appendix de Scarabæis Britannicis," &c. Ray, like many other writers, includes certain tribes of the vermes with inſects, from which they are ſeparated by Linnæus; it is poſſible that Ray might conceive what has been ſince proved by indubitable authority, that ſome few, at leaſt, of the ſuppoſed vermes are no other than the larvæ of inſects.

The work of Albin, for the time in which it was executed, was conſidered as an elegant publication; it is in one volume quarto, containing one hundred copper plates, with a brief deſcription of the objects repreſented in each, and was originally ſold at four guineas a copy, a great price in thoſe times, being publiſhed in the year 1720. If we miſtake not, another edition is dated a few years later; there is certainly one printed with notes and obſervations by Dr. Derham, in 1749. Albin was author of a work on Engliſh ſpiders, in which the lice of ſeveral animals and birds are repreſented from the plates of Redi.

At the ſame time that Albin was engaged in the preparation of the above-mentioned work in England, J. L. Friſch, rector of the Royal Academy at Berlin, was occupied on his hiſtory of the inſects of Germany, "Beſchreibung von Inſecten in Deuſchland," the firſt part of which appeared in 1720; the whole work conſiſts of thirteen parts, and each part is embelliſhed with three plates. Copies of this work have been printed ſince that time; the lateſt we have ſeen bears date 1766.

Valiſinieri, in his work, entitled "Eſperienze et Oſſervazioni intorno agli inſetti," publiſhed in 1730, diſtributes all inſects into four claſſes, according to the different places in which they are found. The firſt comprehends thoſe inſects which live on plants; the ſecond, ſuch as live in water and other fluids; the third, thoſe that live in the earth, or among ſtony ſubſtances; and the fourth, thoſe which ſubſiſt on the other animals, or in their bodies.

Reaumur produced the firſt volume of his "Memoirs pour ſervir à l'Hiſtoire des Inſectes," at Paris, in the year 1734. The five ſucceeding volumes appeared between that time and 1742. This voluminous work contains ſome thouſand pages, and nearly two hundred plates; and is one of the beſt productions on the ſubject that has been ſubmitted to the world. There are two editions of this work, one publiſhed in Paris by its author, in quarto ſize; the other is in octavo, a pirated concern by the Dutch bookſellers.

After the works of Ray, Liſter, and Petiver, the intelligent entomologiſts of our own country, in the commencement of this century, the name of Bradley ought perhaps to have been introduced. His publication, "A Philoſophical Account of the Works of Nature," which was printed in London ſo early as the year 1721, contains a brief account of inſects. This author, though a profeſſor of botany in one of the univerſities, ſeems not to have been poſſeſſed of any very extenſive or accurate information on this ſubject of entomology; his work at leaſt abounds in the marvellous, but was, perhaps, for this very reaſon, more likely in his time to have been peruſed with pleaſure by the common reader. As a popular work, it was not in other reſpects without its advantages. The works of Reaumur in France contributed materially to facilitate the ſtudy of entomology on the continent. And about the ſame time that he was engaged in this field of enquiry, ſeveral tracts and papers made their appearance from other individuals. In the memoirs of the French Academy for 1731, there is one entitled "Eſperiences ſur les Scorpions," by Maupertuis; and in 1734, ſome others by Trew, as "Inſectorum quodam genere," "De duabus Erucis," and "Peculiare quoddam Quercus excreſcentiarum genus," all which are inſerted in the "Commerc. Literar." of Nuremberg. Theſe papers immediately preceded the publication of the firſt entomological work which the celebrated Linnæus produced to the world.

The principal writings of Linnæus on this branch of natural ſcience are to be found in his deſervedly eſteemed production the "Syſtema Naturæ, ſive regna tria naturæ ſyſtematice propoſita per claſſes, ordines, genera, et ſpecies;" the firſt edition of which is in folio, and was publiſhed in 1735. Linnæus in this work diſtributes inſects into four orders, according to the number and form or nature of their wings, under the ſeveral names of coleoptera, angioptera, hemiptera, and aptera. The firſt order contains thoſe inſects which have covered wings; the ſecond thoſe with naked wings, as butter-flies, dragon-flies, ephemeræ, &c. In the third, he enumerates crickets, locuſts, bugs, &c.; and in the fourth, thoſe which have limbs, but no wings, as the ſpider, lobſter, &c. Beſides theſe four orders, this primary arrangement of inſects comprehends three other orders of animals, referred ſince to the vermes claſs, but which, at the period of the firſt publication of the "Syſtema," Linnæus conſidered to be genuine inſects. The firſt of theſe includes all creeping "inſects" whoſe body is naked and deſtitute of limbs, as the earth-worm and the leech: the ſecond, both land and ſea-ſhell animals; and the third, thoſe furniſhed with limbs, as the echinus, aſterias, &c.

Linnæus by no means deviated from the received opinion of his time, in placing the firſt and third of theſe laſt mentioned tribes of animals with inſects. Theſe bodies were conſidered as appertaining to the inſect race by moſt of his immediate predeceſſors, and by ſome naturaliſts in earlier times. In a ſubſequent edition of the Linnæan work, theſe orders are ſeparated, and the latter conſtituted into a diſtinct claſs after the manner of Ariſtotle, who points out the natural obvious difference which prevails between theſe two orders of animals with ſo much clearneſs, that we are not without ſome ſurprize his example was overlooked by Linnæus in the firſt inſtance. Linnæus, according to this plan, in his later works, ſeparates the echini, &c. under the denomination of vermes. The inſects alone were then extended by him from four to ſeven orders. This is the arrangement which his claſs "Inſecta" finally aſſumed in the edition of 1767, and which is ſtill adopted by the admirers of Linnæus. The following are the definitions of the ſeveral orders eſtabliſhed by this eminent naturaliſt.

Coleoptera, ſuch as have cruſtaceous elytra, or ſhells, which ſhut together, and form a longitudinal ſuture down the back of the inſect, as in the chafer-beetle. In moſt inſects of this claſs, the elytra cover the abdomen entirely, in others but partially, as in the ear-wig, &c. The word is derived from κολεὸς, *a ſheath*, and πτερὸν, *a wing*.

Hemiptera, which have their upper wings moſt commonly half cruſtaceous, and half membranaceous, not divided by a longitudinal ſuture, but incumbent on each other; as in the water ſcorpion and graſshopper. From ἥμισυ, *half*, and πτερὸν, *a wing*.

Lepidoptera, having four wings covered with fine ſcales in the form of powder or meal; as in the butterfly and moth, from λεπὶς, *a ſcale*, and πτερὸν, *a wing*.

Neuroptera. In this order the wings are membranaceous, tranſparent, and naked, and are generally reticulated with veins or nerves; the tail is without a ſting, as in the libellula or dragon-fly. The term is derived from νεῦρον, *a nerve*, and πτερὸν, *a wing*.

Hynenoptera, have four membranaceous wings, and the tail furniſhed with a ſting for various purpoſes, as in the waſp, ichneumon, &c. From ὑμὴν, *a membrane*, or *pellicle*, and πτερὸν, *a wing*.

Diptera, with two wings only, and poiſers as in the houſe-fly; from δύω, *two*, and πτερὸν, *a wing*.

Aptera, have no wings; as the ſpider, &c. from ἀ, *without*, and πτερὸν, *a wing*.

The great perſpicuity of the Linnæan ſyſtem of entomology aroſe from its author having made choice of the moſt obvious characters which inſects afford for the leading diſtinctions of his orders, ſuch for inſtance as the number, texture, and poſition or folds of the wings, or the abſence of theſe parts; and in the conſtruction of the genera, the like attention being devoted to the form of the head, thorax, and wings; and in particular to the ſtructure of the antennæ: theſe latter being conſpicuous in moſt inſects, and ſo infinitely varied in their appearance as to conſtitute in general a permanent definition. That there are other characters which, in the opinion of later entomologiſts, are better adapted to the purpoſe of claſſification the reader muſt be aware, but theſe, although really preferable in ſome reſpects, are perhaps too minute to become always uſeful. The ſtructure of the various parts of the mouth, the character on which the Fabrician ſyſtem is founded, however definitive, and therefore excellent, requires that degree of attentive ſcrutiny in their examination, which is rarely beſtowed by the ordinary obſerver of nature; and which cannot for this reaſon be ſo well calculated for the general purpoſe of diſcriminating the families of inſects, as thoſe which are at once too obvious to be miſtaken.

The ſimplicity of the arrangement adopted by Linnæus, the celebrity of his name, and the princely patronage under which he wrote, conſpired with other favourable circumſtances to render this ſcience more univerſally cultivated, admired, and reſpected about his time, than it had probably been at any former period. The credit due to this naturaliſt for his labours in entomology is great. This we allow, but, let us alſo remember, that he is not alone entitled to our commendation for the arrangement propoſed in his work. We muſt in candour acknowledge the merits of many among his predeceſſors, who wrote under circumſtances of leſs encouragement, and have neverthelеſs excelled in this ſcience: men to whom the writings of Linnæus ſtand in a very high degree indebted, and without the aid of which it is impoſſible to imagine the ſyſtem, which now commands our admiration, could have been produced, at leaſt in its preſent ſtate of purity.

From the various entomological works extant before the time of Linnæus, it may be collected that the hiſtory of theſe creatures was deeply inveſtigated prior to the appearance of his writings; and even that ſyſtem itſelf, the prominent feature of his labours, from progreſſive advancement, had gradually attained to a ſtate of conſiderable perfection. In the works of Ariſtotle and Pliny, in thoſe of Agricola, Aldrovandus, Frenzius, Moufet, Swammerdam, Ray, Wilughby, Liſter, Valliſnieri, and various others whoſe names have been already repeated, we diſtinctly perceive, with ſome occaſional variation, the outline of the ſuperſtructure raiſed in the "Syſtema Naturæ."

Theſe valuable ſources of information furniſhed him with abundant materials, from which he ſelected with profound judgment, and interwove with ability, induſtry, and ſucceſs. Linnæus was in this reſpect commendable; he did not ſuffer his mind to be ſwerved on this occaſion from any ambitious or innovating motives; and ſo far as he deemed it conſiſtent with his plan, he appears to have adhered to the examples of his predeceſſors. The characters of his ordines are to be found in ſeveral earlier publications than his own, and ſo likewiſe are moſt of his genera, and the far greater number of his ſpecies. But theſe he remoulded throughout with ſo much ſkill, that this "Syſtema" conſtitutes the central point in which the ſcattered rays of natural ſcience are concentrated with more preciſion than they really appear in the original authors, to whoſe induſtry he ſtands indebted. It was in the conciſe and very expreſſive ſtyle which Linnæus adopts in all his works, and which was almoſt peculiar to himſelf, that he excelled.

Our limits are inadequate to the fair diſcuſſion of this important ſubject; and of this we feel ſo deeply ſenſible, that for the preſent we ſhall wave all further comment, reſerving to ourſelves a future opportunity for entering upon a more extenſive view of the merits of the Linnæan ſyſtem, as contraſted with thoſe of other authors who have appeared ſince his time, and which have obtained the ſanction of public approval.

After the firſt edition of the “Syſtema Naturæ,” Linnæus wrote ſeveral papers on the ſubject of entomology; ſome of which are printed in the Tranſactions of the Royal Society of Upſal. One of the earlieſt of theſe appeared in 1739, under the title of “Om Renarus Brömſkulor i Lapland;” and another dated Stockholm, in the ſame year, “Tal om Märkwardighter uti Inſecterne.” In 1746, we find a paper, jointly the production of Linnæus and Degeer, relative to the lantern-fly of China (fulgora candeleria); and about the ſame time, his “Fauna Suecica,” an enlarged and improved edition of which was publiſhed in 1761. That elegant inſect, panorpa coa, a ſcarce ſpecies at that period, forms the ſubject of a ſmall Linnæan paper in 1747. His diſſertations “Miracula Inſectorum,” and “Noxa Inſectorum,” bear the ſame date, 1752: they were both printed at Upſal, and poſſeſs merit: the latter is in particular valuable, from the object in the contemplation of the writer. Six years after this he produced a diſſertation, called “Pandora Inſectorum;” the year after, a paper on the coccus; and in 1761, his “Fundamenta Entomologiæ,” a book in thoſe days of conſiderable value as an elementary work, or introduction to this ſtudy. There is a tranſlation of the tract by W. Curtis, printed at London in 1772. His laſt entomological paper is upon the genus pauſus, a curious coleopterous tribe, diſtinguiſhed by the comparatively enormous magnitude of the antennæ.

The work of L'Admiral, entitled “Naawkeurige Waarneemingen van Geſtaltverwiſſelende gekorwene Diertjes,” appeared in 1740 at Amſterdam. It is in folio, and contains a ſeries of elaborately finiſhed etchings, which, though engraven in a diſſimilar ſtyle, have ſomewhat the air of Merian's work on the inſects of Surinam, or as is diſtinctly copied in the Aurelian of Moſes Harris. The work of L'Admiral is confined to the European inſects, of which it comprehends about fifty ſpecies of the larger kinds, and thoſe principally of the lepidopterous tribe. Theſe are repreſented in a heavy, though not unpleaſing, and often very beautiful manner, in various attitudes, with large branches of the different kinds of plants on which they feed; and in moſt inſtances, the perfect inſect is accompanied on the ſame plate with the larva and pupa. L'Admiral's work began in numbers, and was intended to contain, according to its author, one hundred plates and four hundred pages of letter-preſs. This deſign was never completed. There are few copies with more than twenty-five plates, and about five pages of letter-preſs. Our copy contains thirty-two plates and twenty pages, and is the moſt complete in this reſpect we have ſeen.

A ſmall treatiſe relative to the larvæ of phalænæ, by Detharding, “Diſquiſitio Phyſica Vermium in Norvegia, qui novi viſi,” was publiſhed in quarto in 1742. The ſame year, the tarantula ſpider engaged the attention of Franceſco Serao of Naples, who on this ſubject only has given a quarto of two hundred and ſixty pages, entitled, “Della Tarantola o vero Falargio di Puglia.” The hiſtory of the tarantula about this time engaged the pen of ſeveral curious perſons; and, among others, N. Caputus had the year preceding publiſhed a book nearly the ſame ſize, “De Tarantulæ Anatome et Morſu.”

The work of Leſſer, “Inſecto-theologia,” &c. written in the German language, and better known from the French tranſlation by Lyonet in 1742, entitled “Theologie des Inſectes,” is rather a curious than valuable publication. The ſucceſs of this book in Germany renders it worthy of particular mention. The views of its author, (a clergyman at Nördhauſen,) as he himſelf explains, was to “promote the glory of God.” He does not aſpire to the eſtabliſhment of any new facts relative to entomology: his attention is directed ſolely to the ſelection of ſuch anecdotes and particulars of the hiſtory of inſects, gleaned from other works, as could be rendered a convenient medium for the theological remarks with which his pages abound. The piety of his mind we ſhall not diſtruſt: to an entomologiſt his work is of no material worth; he was not very well acquainted with this ſubject, and his remarks are often erroneous. As a theological production, and in this view the author wiſhed it to be conſidered, certain paſſages in the work of Leſſer may have an uſeful tendency: it is calculated to expoſe ſome glaring errors in the writings of other theologians, who in a ſpirit of fanaticiſm had entered upon the ſame ſubject. One of his beſt chapters on this head is that relating to the “abuſe of inſects in theology;” in which he points out the groſs outrage on reaſon committed by the pagans, in making certain inſects the idols of their worſhip; and remarks how much more abſurd it muſt appear, that the Jews and even Chriſtians ſhould have followed their example: a fact inferred by him from various authorities. The Jews are accuſed of ſtating many wonderful things relative to inſects, which can only be conſidered as fables. Among others, after repeating the ſacred text, 1 Kings, vi. 7. concerning the erection of the temple, which was “built of ſtone made ready before it was brought thither; ſo that neither hammer, nor ax, nor any tool of iron was heard in the houſe, while it was building,” he ſtates, that the Jews explain this paſſage in the following manner. The workmen, they affirm, employed a worm to ſhape the ſtones; which inſect, named ſchamir, cut and broke them to pieces in places where applied. They add, that it was the figure of a grain of barley, and was kept in a leaden box, becauſe, had it reached any rocks, it would have cleft and deſtroyed them. This fable, with ſome others invented by the rabbis, is particularly mentioned. Among the legends of Catholic ſuperſtition he ſelects other anecdotes equally remarkable. Baldus, he ſays, in order to prove the real preſence in the euchariſt, relates that a number of bees being found on holy ground, paid it homage, and carried a portion of it reſpectfully to their hive. Baptiſte tells us, that a ſpider having accidentally fallen into the chalice, while St. Francis was ſaying maſs, the holy man determined to ſwallow it; and adds, that the ſpider came afterwards out of the bone of his leg. But to conclude with one of theſe tales of fanaticiſm not unworthy of record with the reſt: it is gravely ſtated that St. Francis, once walking in a garden, ſaw a graſshopper, which immediately quitted the plant it ſat upon, and perched on his hand; he ordered it to ſing to the praiſes of God, and with a pretty loud voice it immediately began a very fine pſalm! If ſuch holy impoſtures were actually liſtened to with any faith, the time of Leſſer could not be miſapplied, as a divine, in endeavouring to expoſe their abſurdity.

Degeer publiſhed at Stockholm, in the year 1744, an intereſting little octavo on the utility of the ſtudy of inſects, called “Tal om nyttan, ſom Inſecterne och deras ſkärſkâdande, tilſkynda oſs;" in which he points out the advantages likely to reſult from our acquaintance with this tribe of animals, and which appears to be the firſt tract expreſsly written under this view of entomology. About this ſame period, Röſel of Nuremburg, by profeſſion a miniature painter, was engaged in the preparation of a valuable entomological work, the firſt part of which was ſhortly after produced to the world. This work bears the title "Der Monatlich-herausgegebenen Inſecten-Beluſtigung," and conſiſts of ſeveral volumes in quarto. The firſt part was produced in 1746, and two ſucceeding volumes in 1749 and 1755; to theſe a fourth volume was added by his relation Kleemannin, 1761, two years after the death of Röſel; and ſince that period Kleemanahus publiſhed three other parts in continuation.

Röſel does not adopt any ſcientific order of arrangement: his work was produced as a miſcellany, and, according to the title, as an amuſement in the ſtudy of inſects. Many of the inſects included are European; others are natives of Aſia, America, &c. Beſides inſects, ſome few of the cruſtacea are contained; and a portion of the third volume is devoted to the vermes tribe. The text is in the German language, and exceedingly copious; the ſlighteſt peculiarity in every individual inſect being deſcanted upon with as much minuteneſs as the more important details of its hiſtory. The plates are numerous and intereſting. The ſupplemental faſciculi, given by Kleemann, "Beyträge zur Natur-und Inſecten-Geſchichte," &c. relate to European inſects, and a ſmall number of the extra European kinds.

A tract, dedicated to the purpoſe of explaining the advantages ariſing from the ſtudy of inſects, was printed in 1747, by C. F. Mennander, "Diſſertatio de Uſu Cognitionis Inſectorum." Bazin, the ſame year, publiſhed his "Abregé de l'Hiſtoire des Inſectes, pour ſervir de ſuite à l'Hiſtoire naturelle des Abeilles," in Paris; and in London, William Gould, "An Account of Engliſh Ants." T. C. Hoppe publiſhed, the year after, two ſmall entomological tracts, as "Antwort-Schreiben auf Hrn Schreibers zweifel," at Gera; and "Eichen-Weiden-und Dornroſen," at Leipſic; and J. Dutfield of London, ſix numbers of a natural hiſtory of Engliſh moths and butterflies, after which the work diſcontinued.

About this ſame period, or rather earlier, but certainly before the year 1749, a work was undertaken in London by Benjamin Wilks, under the title of "The Engliſh Moths and Butterflies, together with the Plants, Flowers, and Fruits whereon they feed, and are uſually found." This publication, conſiſting originally of plates only, appeared in the firſt inſtance without a date. From collateral circumſtances we are, however, enabled to ſtate that it muſt have preceded the year laſt mentioned; becauſe at that time the whole work, conſiſting of 120 plates, was nearly completed, as we learn from comments upon that work in the third volume of Röſel's Inſecten Beluſtigung. The nature of this work is rather incorrectly ſtated in its title page; for the plants on which the groups of inſects are reſpectively diſplayed are not thoſe which conſtitute their natural food: they conſiſt of gaudy flowers, auriculas, roſes, monſtrous varieties of cultured plants, fruits, &c. the introduction of which, in preference to their natural food, has incurred blame. But another charge, and one in our opinion of more importance, is brought againſt our author by Röſel; an imputation tending to depreciate the reſpectability of the Engliſh entomologiſts of that particular criſis, when the ſcience ought, from the labours of former writers, to have ſtood in this country on very high ground, and the public judgment to have been ſo far matured as to diſcover impoſition. He plainly accuſes our author of piracy; and when we reflect on the celebrity this work has heretofore enjoyed as an original production, it does attach ſome little reproach at leaſt that facts ſtated with the utmoſt publicity on the continent ſhould have remained unknown to us. The remarks are curious; and as in all probability they have not before met the eye of the Engliſh reader, we ſhall tranſlate the paſſage in this place: "In dem nachtragoder 3," &c. "In the ſupplement, or third part of my Amuſements of Inſects, I have mentioned a certain work which Mr. Wilks in London publiſhes monthly, and promiſed that I would be more circumſtantial at another time. Since then the plates amount to ninety, all which I have examined with great attention: they are as yet deſtitute of any deſcription, which, however, is to appear at ſome future period. If the notice which accompanies theſe plates deſerves credit, all thoſe inſects are drawn after life; but to thoſe who know other works, and examine theſe plates with caution, it ſoon appears that the author has copied ſeveral from Albin's inſects, from Merian's book, and a great many from my own. Whether he has been ſucceſsful in his attempt, I leave to the judgment of others. An ape mimicks every thing, but does not always ſucceed. This may appear to many to be too ſevere; but let them conſider that the author counterfeits the works of others, and gives them out as his own. I venture to aſſert that in the future deſcription of his work, he will take care not to tell us from what books he has compiled his own; for he already ſtrives to hide on his plates whatever he has copied from others, by reverſing the figures, or by giving them a different poſition." Vol. iii. p. 192, A.D. 1749. This we muſt conſider as in ſome meaſure the language of reſentment for the liberties taken with his work: it is nevertheleſs in ſubſtance true; for the eye of the artiſt will perceive, on comparing the two publications, that Wilks has taken an unlimited range through the firſt volume of Röſel. The remarks are repeated at length, becauſe we wiſh to impreſs on the public mind the value and importance of any genuine work, in preference to productions of this nature. Wilks was the publiſher of "Twelve new Deſigns of Butterflies," in which the inſects are diſpoſed in ſtars, feſtoons, circles, or other whimſical groups, forming what are uſually denominated "Butterfly pictures."

The firſt volume of the invaluable work of baron Charles de Geer, the "Memoirs pour ſervir à l'Hiſtoire des Inſectes," was printed at Stockholm in 1752, and was received with every demonſtration of praiſe, to which its merits are entitled. From the teſtimony of the author's talents which this volume afforded, the continuation was expected with impatience; but nine years elapſed before the ſecond volume appeared, and it was altogether twenty-ſix years from its commencement to its termination. It was completed in 1778, in which year the labours of its author cloſed with his life. De Geer was the author of many other publications, which are to be found diſperſed through the Tranſactions of various learned ſocieties; but that above noticed is the moſt conſiderable of his works.

Dr. Hill, in his hiſtory of animals, publiſhed in London in the year 1752, divides inſects into three claſſes: the firſt of which, apteria, comprehends all inſects without wings; the ſecond, pteraria, is devoted to the winged kinds; and the third, called gymnarthridia, conſiſts of thoſe which have ſoft and naked bodies, and are furniſhed with limbs. The apteria is divided into two families; and pteraria, or the winged inſects, into diptera and tetraptera, or thoſe with two wings and four wings.

The "Entomologia Carniolica" of Scopoli appeared in 1753.

1753. This author diſtributes all the inſects of which he treats into orders, genera, ſpecies, and varieties, nearly after the manner of Linnæus; changing, nevertheleſs, the names they bear in the works of the latter for others he deemed more appropriate. Thus, for example, proboſcidea is ſubſtituted for hemiptera, in reference to the beak by which theſe inſects are diſtinguiſhed; aculeata for hymenoptera, from the abdominal ſting; halterata for diptera; and pedeſtria for aptera.

As a ſyſtematic work, this publication of Scopoli is of ſmall importance; in other reſpects it is valuable. The arrangement of inſects, better known on the continent as the ſyſtem of Scopoli, appeared in a work, entitled "Introductio ad Hiſtoriam naturalem," printed ſo lately as the year 1777, and which, as the title expreſſes, does not relate excluſively to the ſcience of entomology. He divides inſects into five tribes, under the ſingular appellations of Swammerdamii-lucifuga, Geoffroy-gymnoptera, Roeſelii-lepidoptera, Reaumurii-proboſcidea, and Friſchii-coleoptera: by this means, identifying each particular tribe with the name of an author, who in his opinion had been moſt ſucceſsful in the explanation of that to which his name is attached.

The order lucifuga includes two genera, cruſtacea and pedicularia; gymnoptera comprehends halterata, aculeata, and caudata; lepidoptera, the genera ſphinx, phalæna, and papilio; proboſcidea are divided into two parts, the terreſtrial and aquatic; and the coleoptera, in the ſame manner, conſiſt of two families, the inhabitants of the water and thoſe of the land.

The ardour with which the ſcience of entomology was cultivated about this period in various parts of Europe, is to be aſcribed to the occaſional labours of Linnæus and his immediate coadjutors, whoſe example excited the moſt laudable aſſiduity; and though no work of any material conſequence appeared exactly at this time, we may ſafely conclude that this ſpirit of emulation laid the foundation of ſeveral which were ſubmitted to the world a few years after. Among the entomological tracts and papers of this time, ſome only are worthy of notice. Kalm, a name familiar to the botaniſt, beſtowed attention on this ſubject, as we perceive from a paper on a ſpecies of cicada, (ſeptemdecim,) written in the Swediſh language; and alſo from another by the ſame author on acarus americanus: theſe appeared in 1754. The year after G. W. Sigwart treats ſlightly on coleopterous inſects; and Sauvages produced ſome papers of little moment in the Memoirs of the French Academy. And now we proceed gradually to the conſideration of other works of greater conſequence; the uſeful work of Clerk on the ſpiders of Sweden, printed in 4to. at Stockholm, in 1757, is one of the beſt works extant on this curious tribe. Another production by the ſame author is alſo valuable, his "Icones inſectorum rariorum," a thin and ſmall quarto, publiſhed two years after. Indeed, this laſt mentioned work may be conſidered as having the immediate ſanction of Linnæus, from being produced under his own direction, and, we believe, inſpection. The work contains a moderate number of coloured plates, ſome of which are appropriated to the diſplay of ſelect exotic inſects of the moth and butterfly tribe, and others to the mere choice and rare lepidopterous inſects of Europe, all which are highly finiſhed in colours. There were only a few copies of this work printed off, and it is now become ſcarce, and bears a conſiderable piece. Dr. Smith poſſeſſes one copy, that originally in the library of Linnæus, and there is another in that of ſir Joſeph Banks.

An intereſting little work, called "Inſecta Muſei Græcenſis," from the pen of Nicolaus Poda, publiſhed in 1761, affords an account of the inſects of Greece, arranged in the Linnæan manner. The ſame year an introductory work to the ſtudy of inſects by J. H. Sulzer, was printed at Zurich: it is in quarto, with a number of plates, and bears the title of "Die Kennzeichen der Inſekten durch 24 kupfertafeln erläutert, und mit derſelben natürlichen geſchichte begleitet." The ſame writer, in 1776, produced another publication alſo introductory to the ſcience of inſects, called "Abgekürtze geſchichte der Inſecten," illuſtrated with thirty-two coloured plates; which latter, with five or ſix additional plates, form the hiſtorical part of the quarto work publiſhed in Switzerland, in 1789, by J. J. Roemer, as an elucidation of the Linnæan and Fabrician ſyſtems. The title of the latter is "Genera Inſectorum Linnæi et Fabricii iconibus illuſtrata." The outline of the Fabrician ſyſtem, which this work contains, is conformable with that propoſed in the earlieſt work of the laſt mentioned entomologiſt.

As a ſyſtematic production, the work of Geoffroy, printed at Paris in 1762, demands the particular attention of the modern entomologiſt. The work is entitled "Hiſtoire abrégée des Inſectes," and compriſes all the inſect tribes in the ſix following claſſes: 1ſt, coleopteres; 2d, hemipteres; 3d, tetraptères à ailes farineuſes; 4th, tetrapteres à ailes nues; 5th, dipteres; 6th, apteres. The firſt claſs correſponds with the Linnæan coleoptera; the ſecond is more accurately regulated by the form of the proboſcis; the third agrees with the lepidoptera, having the wings covered with fine powder; the naked-wing tribe unite the neuroptera and hymenoptera; the dipteres and apteres are the ſame with the Linnæan orders. It is a material diſtinction of this ſyſtem, that the characters of the orders are determined chiefly by the number of joints in the feet; the generical characters are taken from various parts of the body, wings, &c. The genera differ exceedingly in their conſtruction from thoſe of Linnæus, and many of them are in uſe to this day among the continental writers.

Brünniche is the author of two entomological tracts, printed about the ſame period, as, "Prodromus Inſectologiæ Siællandicæ," and an elementary work in Latin and Daniſh, called "Entomologia ſiſtens Inſectorum tabulas ſyſtematicas, cum introductione et iconibus." Sepp began his work, "Beſchouwing der wondern gods in de minſtgeachte ſchepzelen of Nederlandſche Inſecten," in the year 1762; it is dedicated entirely to the more uncommon moths and butterflies of Holland; the text is in the Dutch language, and the plates, which are not numerous, are admired for their peculiar neatneſs, being engraven in the dot or ſtipple ſtyle, with conſiderable delicacy.

This elaborate kind of engraving was in great eſteem about the period adverted to, as appears from the encomiums beſtowed on the plates executed by the hand of Lyonet, for his laborious work, "Traité Anatomique de la Chenille," printed in Holland the ſame year. This work of Lyonet is a treatiſe dedicated ſolely to the anatomy of the caterpillar, which lives in the wood of the willow, (phalæna coſſus,) upon the diſſection of which this author enters with ſuch minuteneſs of inveſtigation, that his deſcriptions of this object alone occupy rather more than ſix hundred quarto pages. The plates, eighteen in number, with the exception of the firſt, which repreſents the microſcope employed in his examinations, are entirely appropriated to the repreſentations of the muſcles, tendons, fibres, medullary veſſels, ſpiracles, &c. every part of which throughout the whole animal are exhibited in their natural and magnified appearance. Theſe plates, as before intimated, are finiſhed ſpecimens of the ſtipple ſtyle of engraving then prevalent, and which, from the cloſeneſs of its texture, nearly reſembles mezzotinto.

Lyonet is ſaid to have left at his death two manuſcripts on the ſubject of entomology, neither of which have, to our knowledge, appeared before the world. One of theſe is inſcribed "Œuvres Melées ſur les Inſectes," and contains his obſervations on the inſects found in the environs of the Hague, where he reſided. The other, an "Eſſai Anatomique ſur la Chryſalide et la Phalene qui range le bois de ſaule," a work on the ſame plan, and forming a continuation of the hiſtory of the ſame inſect, as his former eſſay on the caterpillar. This unpubliſhed work on the chryſalis and fly was to be accompanied by no leſs than fifty-four plates, all the drawings of which were executed, and ſome of the plates engraved, previouſly to the death of the author, which happened, at an advanced age, in 1789.

The ſcience derived ſome improvement from the various publications of Schæffer between the years 1764 and 1777. He produced, among others, an elementary work in German, "Zweifel und Schwürigkeiten, welche in der Inſectenlehre annoch vorwalten," and another, entitled "Elementa Entomologica," containing no leſs than 132 plates, appropriated to the illuſtration of the principles of his ſyſtem; and an additional ſection with two more plates, deſcribing the various apparatus for catching, and the manner of feeding inſects, microſcopes for examining them, &c. "Vierter abſchnitt von den Werkzeugen der Bedhandlung und Sammlung der Inſecten." The moſt important of Schæffer's works, is that entitled "Icones Inſectorum circa Ratiſbonam indigenorum," compriſed in three volumes 4to. with a vaſt number of coloured plates, the latter of which poſſeſs a character of great peculiarity in having two impreſſions on every print, one on the front of the leaf as uſual, and the other on the back; by which means the plates are compriſed in half the number of leaves they would otherwiſe occupy. The claſſification of Schæffer differs extremely from that of Linnæus; it approaches that propoſed by Geoffroy, from which, however, it is ſtill ſo far diſtinct, that being a ſyſtem in ſome repute, it may not be amiſs to preſent an outline of it in this place.

Schæffer divides all inſects into ſeven claſſes, in the following manner;

1. Inſecta coleoptero-macroptera, inſects whoſe elytra are cruſtaceous throughout their whole length, and extend beyond the abdomen when cloſed.

2. Inſecta coleoptero-microptera, differ from the former only in having the wing-caſes ſhorter than the abdomen.

3. Inſecta coleoptero-hymenoptera, or hemiptera, ſuch as have the elytra half cruſtaceous, or becoming membranaceous towards their extremity.

4. Inſecta hymeno-lepidoptera, or having wings imbricated with ſcales.

5. Inſecta hymeno-gymnoptera, or with naked and membranaceous wings, comprehending the two Linnæan orders neuroptera and hymenoptera.

6. Inſecta diptera, or inſects having two wings.

7. Inſecta aptera, or without wings.

The ſecond part of "Zoophylacium Gronovianum," by Laur. Theod. Gronovius, contains the deſcription of about ſix hundred inſects with ſynonyms after the Linnæan manner, accompanied by four illuſtrative plates. The work is in folio, and was printed at Leyden in 1764.

Seba, in his ſplendid folio work, "Theſaurus Naturæ," publiſhed at Amſterdam in 1765, deſcribes a number of the larger kinds of extra European inſects, with figures executed with great force, and in a ſtyle correſponding with the other plates of his work.

In 1769, Berkenhout publiſhed the firſt edition of his "Outlines of Natural Hiſtory of Britain;" ſince which time two other editions of the ſame work have appeared. That portion of the work which is devoted to entomology includes a ſmall ſelection of the ſpecies moſt conſpicuous for their ſize, under each of the Linnæan genera, the inſects being arranged throughout in the order of that ſyſtem. The number of inſects deſcribed amount to about ſix hundred. The work is deſtitute of figures.

Among the number of exotic inſects figured in the plates of "The Hiſtory of Birds," and the "Gleanings," by George Edwards, ſome are intereſting from their beauty. There are a few alſo remarkable for their rarity, particularly ſcarabæus atlas, one of the three larger "Indian beetles;" libellula chinenſis, called "the green-winged libellula;" and the larva or pupa of an extraordinary gibbous kind of locuſt, repreſented only, we believe, in this work. Inſects were not ſparingly introduced, notwithſtanding that they were conſidered only as ornamental objects, the work being devoted principally to ornithology. In the courſe of the whole of this voluminous production, more than fifty ſpecies of the inſect tribes are noticed, the greater part of which are butterflies. Edwards began this publication in 1743, from which period it was continued progreſſively till 1764. The catalogue was publiſhed in 1770, and forms part of the tracts entitled "Edwards on Natural Hiſtory."

John Reinhold Forſter, one of the eminent naturaliſts who accompanied the celebrated Capt. Cook in his voyage round the world, has left us a catalogue of Britiſh inſects printed in 1770. It is only a liſt of Latin names of a certain number of ſpecies, and was intended as a prelude to the copious work on the inſects of this country, which its author intended to write. This catalogue, however, and his "Novæ Inſectorum Centuriæ," which appeared in London the year after, are the only entolomogical works that author publiſhed. Of the latter we ought to ſpeak more at large. The avowed purpoſe of this little book, as the reader is informed in the preface, was to give a deſcription of one hundred inſects not mentioned in the lateſt work of the illuſtrious Linnæus. The inſects included are partly indigenous, ſome are from China, and others from South America. The greater number of theſe are coleopterous inſects, and are arranged after the manner of Linnæus, though the genera anthribus and ciſtela are taken from Geoffroy. It may be laſtly obſerved, that although theſe inſects do really appear to be undeſcribed by Linnæus, ſome few of them were previouſly made known to the world by the works of Schæffer and Drury. This its author was aware of, but as they had eſcaped the obſervation of the author, whoſe work he was ſolicitous to improve, it was ſtill conſidered right to introduce them.

The firſt volume of the "Illuſtrations of Natural Hiſtory, wherein are exhibited figures of exotic inſects," &c. by D. Drury, was publiſhed in 1770. The plates, fifty in number, form a miſcellaneous aſſemblage of the more beautiful extra European inſects, which the extenſive collection of its author afforded. The ſecond volume was produced three years after the firſt; and the third, which concludes the work, ſo far as the author proceeded with the publication, appeared in 1782. Beſides the inſects repreſented in theſe volumes, the extenſive cabinet of the author contained many very choice ſpecimens, reſerved as materials for the fourth volume which was in contemplation; and among the reſt, a number of curious ſpecies collected in the interior of Africa, and other countries rarely viſited by Europeans, the introduction of which would have rendered the fourth volume of much greater intereſt to the entomologiſt than either of the preceding; this may be collected from the manuſcripts of Mr. Drury, in the poſſeſſion of the writer of this article, and which are now before us. From an inſpection of theſe papers, it likewiſe appears, that the author intended, in a reviſal of his former volumes, to have aſſigned the Fabrician names to all the inſects contained, ſo far as theſe could be obtained, and that for this purpoſe Fabricius had himſelf furniſhed Mr. Drury with a number of names and references, independently of thoſe which had been publiſhed in his "Species Inſectorum," a paper by Sebaſtiani, "Inſecta ad aquas Mattiacas ſuper nive deprehenſa," bears the ſame date with Drury's firſt volume of exotic inſects, and as nearly as we can aſcertain Kahn was about this very period engaged at Berlin in his publication "Anecdoten zur Inſekten-geſchichte," a work written in German, and publiſhed in numbers. The tract of Kahn, relative to the mode of catching and preſerving inſects, called "Kurze anleitung Inſecten zu ſammlen," is dated 1773.

The "Inſtitutions of Entomology," by Thomas Pattinſon Yeats, is the only production of its unfortunate author relative to this ſubject: it is a tranſlation of the Linnæan orders and genera, collated with three other ſyſtems, namely, thoſe of Geoffroy, Schæffer, and Scopoli, together with obſervations by the tranſlator. This was a valuable book at the time of its production. In the preſent day it is become rather obſolete; and it is in particular defective in the compariſon drawn between the Linnæan ſyſtem and that of Scopoli; not from any error of the tranſlator, but an event that could not be anticipated. Scopoli coincided nearly with Linnæus in his arrangement of inſects, when he wrote his "Entomologia Carniolica;" after which, however, he abandoned that method, and adopted another; that which has ſince obtained currency on the continent under the name of "Scopoli's Syſtem." This laſt mentioned work was not printed till four years after the tranſlation by Yeats.

"The Aurelian's Pocket Companion," by Moſes Harris, is a kind of alphabetical catalogue of the larger butterflies, ſphinges, and moths collected in England by its author: a tract of no utility to the naturaliſt, unleſs he firſt condeſcends to become an adept in the jargon of the aurelian, or, as now termed, the entomological ſociety; the inſects being throughout deſignated by the ſilly names impoſed by the few illiterate perſons aſſociated under this denomination. In this Engliſh lexicon of entomology, we have "The Wall," "The Bank," "The Turnpike-gate Keeper," "Ghoſt," "Old Woman," "Diſh-clout," and a vaſt number of others equally capricious and replete with abſurdity.

J. C. Fabricius, the indiſputable founder of a new ſyſtem of entomology, publiſhed in the year 1775, his "Syſtema Entomologica," in which the principles of his novel mode of claſſification is for the firſt time developed. The eſſential characters of the claſſes are determined from the organs of manducation, or mouth (inſtrumenta cibaria). In this work inſects of every deſcription are comprehended in eight claſſes to which the ſeveral names of eleutherata, ulonata, ſyneſtata, agonata, ungonata, gloſſata, rhingota, and antliata, are aſſigned.

This work obtained for its author very high reputation, and ſuch further inducements to the proſecution of his entomological ſtudies, that in the courſe of a few years after ſeveral other works appeared from his pen on the ſame ſubject, among which were his "Species Inſectorum," "Entomologia Syſtematica," &c. in all which his original manner of claſſification was adopted with progreſſive improvement. His "Supplementum Entomologiæ Syſtematicæ," preſents an outline of his ſyſtem in its lateſt ſtate, and is the baſis on which the laſt work in which he was engaged, his "Syſtema Eleutheratorum" was undertaken. Part only of this valuable work has hitherto appeared, its completion being impeded, if not finally interrupted, through the death of the author; but ſo far as he did proceed, the arrangement propoſed in his ſupplement is adopted, and we cannot entertain any other concluſion than that it would have been acceded to throughout. This may hence be admitted as the beſt he had formed in the opinion of its author, and a concluſion, the reſult of ſo much extenſive knowledge in the ſcience as Fabricius poſſeſſed, deſerves our ſerious conſideration.

In this ſyſtem Fabricius diſtributes all inſects into thirteen claſſes, the characters of which are as follow:

Claſs 1. *Eleutherata.* Jaws bare, free, and bearing feelers.

2. *Ulonata.* Jaws covered by an obtuſe mouth-piece

3. *Syniſtata.* Jaws elbowed near the baſe, and connected to the lower lip.

4. *Piezata.* Jaws horny, compreſſed, and uſually elongated.

5. *Odonata.* Jaws horny, dentated; palpi two.

6. *Mitoſata.* Jaws horny, vaulted; no palpi.

7. *Unogatæ.* Jaws horny, unguiculated.

8. *Polygnata.* Jaws ſeveral (uſually two) within the lip.

9. *Kleiſtagnatha.* Jaws ſeveral, outſide the lip.

10. *Exochnata.* Jaws ſeveral, outſide the lip, and covered by the palpi.

11. *Gloſſata.* Mouth compoſed of a ſpiral tongue, ſituated between two palpi.

12. *Rhyngota.* Mouth compoſed of a beak or articulated ſheath.

13. *Antliata.* Mouth compoſed of a ſucker, not articulated.

This able entomologiſt is the author of various tracts on entomology, written in the Latin and German languages; and alſo of two principal introductory works, "Genera Inſectorum," and "Philoſophia Entomologia."

The inſects of Switzerland are deſcribed by J. C. Fueſſlin, in an intereſting little work, to which its author gives the title "Verzeichnis der ihm bekannten Schweitzerſchen Inſeckten," printed at Zurich, and bearing the ſame date (1775) with the Fabrician "Syſtema Entomologica."

The number of inſects figured in the "New Illuſtrations of Zoology," by Peter Brown, in 1776, is by no means conſiderable; ſome few of which it does contain are nevertheleſs ſufficiemtly important in point of rarity to deſerve explicit mention. The purple-winged locuſt is, in particular, a magnificent inſect: at the time this artiſt made his drawing, the ſpecimen, which is preſumed to be unique, was in the poſſeſſion of Mr. Tunſtal; at preſent it enriches the ſplendid collection of Mr. Macleay. The work of Stoll, it ſhould be obſerved, affords likewiſe a figure of this ſpecies, and which, it is believed, was taken from the ſame ſpecimen previouſly to its being purchaſed in Holland for Mr. Tunſtal.

The extenſive ſyſtematic work of J. A. E. Goeze, called "Entomologiſche beyträge zu des Ritter Linné zwölften aufgabe des Natur ſyſtems," began to be publiſhed at Leipſic in 1777, and was continued progreſſively in parts till 1783. In the ſame year, with the commencement of this publicaton, Eſper produced in Germany the firſt part of his uſeful book on the lepidopterous tribe of inſects, "Die Schmetterling in Abbildung nach der natur mit beſchreibungen," a work with many plates, and of which a ſecond part was publiſhed in 1779. Between that time and 1786 two other parts appeared likewiſe, and which altogether form a very extenſive publication. Two other very coſtly works, devoted excluſively to this beautiful order of inſects, were alſo begun in 1779, one at Paris in the French language; the other in Holland, and in the language of that country: the firſt of theſe is entirely appropriated to the inſects of Europe, and is named "Papillons d'Europe, peints d'après nature;" the latter is by Pieter Cramer, and conſiſts of the extra European ſpecies. The title of this work is, "De uit landſche kapellen, voorkomende in de drie waereld deelen Aſia, Africa, en America," and including the continuation publiſhed about the year 1782, conſiſts of four volumes quarto, with many plates. The production of theſe expenſive works ſufficiently demonſtrates the encouragement beſtowed on the ſubject of entomology upon the continent of Europe.

An elementary work by James Barbut, bearing the title of "The Genera Inſectorum of Linnæus, exemplified by various ſpecimens of Engliſh Inſects," was publiſhed in London in 1781; and which, beſides the text, contains altogether about twenty-two plates, two of which are explanatory, and the reſt comprehend indifferent figures of a ſmall number of ſpecies in each genera. As an illuſtration of the Linnæan ſyſtem, this work may be in ſome reſpects uſeful to the Engliſh reader: its views are too limited to admit of more general utility. The author does not ſeem to be aware of the improvements the ſcience had undergone upon the continent, in the interval between the publication of the "Genera Inſectorum" of Linnæus, and the time in which he wrote, and has not therefore drawn thoſe compariſons between them, which, without innovation on either, could not fail to have placed the ſcience in a more lucid point of view. It is, indeed, to the ſilence of Engliſh writers in this reſpect, generally ariſing either from the want of information, from ſentiments of illiberality, or from negligence, that we muſt aſcribe the very low ſtate of entomological knowledge in Britain, even to the preſent period. Franciſcus de Paula Schrank diſtinguiſhed himſelf by his enumeration of the inſects of Auſtria in 1781, written in Latin, "Enumeratio Inſectorum Auſtriæ indigenorum," afterwards rendered into German by Fueſsly. The ſame year John Nepomuk von Laicharting publiſhed at Zurich his catalogue of the inſects of the Tyrol, "Verzeichniſs und beſchreibung der Tyroler Inſecten," a ſecond part of which appeared in 1784. Laicharting adopts a ſyſtem ſomewhat different from that of Linnæus; he divides inſects into ten claſſes, characterized from various parts of the body. His claſſes are ſcarabæides, grylloïdes, cimicoïdes, papilionoïdes, libelluloïdes, veſpoïdes, muſcoïdes, cancroïdes, aranoïdes, and oniſcoïdes. In 1782, a paper by Morand was publiſhed in the Tranſactions of the Paris Academy, entitled "Memoire ſur les vers de Truffes, et ſur les mouches qui en proviennent." A ſmall octavo by J. S. Semler, in the German language, bears the ſame date, and is worthy of attention, "Verſuch eines Diarium über die Œconomie mancher Inſecten im Winter," and there is beſides this another more extenſive book printed in 1783, relative to the aphides, called "Nachleſe zur Bonnetiſchen Inſektologie." A catalogue of lepidopteræ, written by Lang in the German language, came out in the ſame year. And, laſtly, a "Short hiſtory of the brown tail Moth," by W. Curtis. The caterpillars of this moth, it may be recollected by many readers, appeared in ſuch immenſe ſwarms in the fields ſurrounding London during the ſummer of 1782, and from their ravages deſpoiled ſo many trees of their foliage, as to create very ſerious apprehenſions of approaching deſtruction to the whole vegetable tribe. The object of this pamphlet was to prove that graminiferous plants, not being the natural food of theſe voracious vermin, would eſcape their attack. This circumſtance alone will ſerve to teſtify, that ſome benefit at leaſt may reſult from an acquaintance with the ſcience of inſects. Its author was by this means enabled to diſpel the uneaſineſs occaſioned through the appearance of theſe ſuppoſed miniſters of famine; and which prevailed to ſuch an alarming extent throughout the whole population of this vaſt metropolis, that prayers were ordered to be read in all the churches to avert the impending calamity.

An elementary work by J. A. B. Bergſtræſſer, a ſmall octavo, entitled "Entomologia, ſcholarum in uſus concinnata," was publiſhed in 1784; this author had previouſly diſtinguiſhed himſelf by his German work, entitled "Nomenclatur und beſchreibung der Inſecten in der Grafschaft Hanau-Müntzenberg," &c.

The entomological tracts publiſhed about this period, and rather earlier by Thunberg, contributed to promote this ſcience; his diſſertations, named "Novæ Inſectorum," of which ſeveral appeared between 1781, and ten years after; and alſo his "Diſſertatio ſiſtens Inſecta Suecica," the firſt of which occurs in 1784, are intereſting. The relation of his travels to the Eaſt abounds with information reſpecting natural hiſtory, and relates in ſome degree to entomology; and he alſo produced a curious memoir on the pauſus genus, called "Beſkrinfning poa tuänne nya Inſecter," beſides other tracts in the Swediſh and Latin languages.

Retzius, in 1783, produced his "Genera et Species Inſectorum," in which the method of Degeer is ſimplified, and the Linnæan terminology adapted to that performance. Inſects, according to this ſyſtem, are divided into fourteen claſſes; namely, lepidoptera, alinguia, neuroptera, hymenoptera, ſiphonata, dermaptera, hemiptera, coleoptera, halterata, proboſcidea, ſuctoria, ancenata, atrachelia, and cruſtacea.

Harrer wrote on the inſects of Germany, in a ſmall book printed in 1784. The year after Jablonſky began the important ſyſtematical work, called "Natur ſyſtem aller bekannter in-und auſländiſchen Inſecken," printed at Berlin; about the ſame time Fourcroy publiſhed his catalogue of the inſects found in the neighbourhood of Paris in Latin, under the title of "Entomologia Pariſienſis;" and another illuſtration of the elements of entomology, written in German, appeared at Leipſic from the pen of Schmiedlein. Some African inſects, that inhabit the Cape of Good Hope, were deſcribed in 1786 by Xavier Walfen; and two publications on the lepidopteræ of Germany, and both written in the language of that country, came out in the ſame year, one by W. Geſenius, the other bearing the title of "Beitrage zur geſchichte der Schmetterlinge," and printed at Augſburg, is by Hübner.

The inſects of Naples are deſcribed by Dominicus Cyrillus in a folio work publiſhed in 1787, called "Entomologiæ Neapolitanæ." A curious and uſeful little tract on the oeſtrus, or gad-fly genus, was the ſame year printed at Leipſic by J. S. Fiſcher under the title of "Obſervationes de Œſtroovino atque bovino factæ," to which a copious appendix was annexed in 1788. The cochineal inſects diſcovered at Madras ſome few years before, gave riſe to a ſeries of letters on this important ſubject, by James Anderſon, addreſſed from Madras to ſir Joſeph Banks, fourteen of which were printed together in that country in the year 1788; there are, beſides theſe, two other letters which have been publiſhed ſince, alſo a ſeparate publication by the ſame author, containing an account of the importation of American cochineal inſects into Hindooſtan. Swederus, in 1788, publiſhed a monograph on that curious coleopterous genus terapterus, in a memoir entitled "Beſkrifuing poa elt nytt genus ibland inſecterna, hörande til Coleoptera."

The ſcience of entomology obtained ſome further advantages about this period, from the publication of the enlarged edition of the Linnæan "Syſtema Naturæ," by J. F. Gmelin; not from poſſeſſing in itſelf any peculiar merit, but becauſe as a general, and therefore uſeful work, it combines much valuable information, compiled from the labours of various naturaliſts of the firſt conſequence ſince the time of Linnæus. In the entomological part, conſiſting of three volumes, publiſhed at Leipſic in 1788, the editor is conſiderably indebted to the writings of Fabricius; for although he rejects his mode of claſſification, his orders, and moſt of his genera, he has copied no inconſiderable portion of his new ſpecies, and by that means very materially augmented and improved the original work of Linnæus. Beſides this, the pleaſing works of Stoll contributed about this time to facilitate the ſtudy of the hemipterous order of inſects, from affording ſigures of many extraordinary ſpecies of the locuſt, fulgora, cicada, cimex, and other tribes, extant in the various continental cabinets at that time, and, among others, that of the prince of Orange. His firſt work is called "Natuurlykye af beeldingen en beſchryvingen der Cicaden in alle vier waerelds deelen." The two publiſhed ſince are only a continuation, including other genera beſides the cicadæ, as the locuſtæ, phaſmæ, &c. Theſe works were printed at Amſterdam. The work of M. B. Borkhauſen, written in the German language, relates entirely to European inſects of the lepidoptera kind, and bears the title of "Naturgeſchichte der Europaiſchen Schmetterlinge nach Syſtematiſcher ordnung." The firſt part appeared at Franckfort in 1788; and ſince that time the work has been conſiderably extended. The article entomology, inſerted in Hall's Encyclopædia, as it appeared originally in 1788, was written by Marſham, and is exemplified by three plates; and about the ſame time, Roemer publiſhed in Switzerland his "Genera Inſectorum Linnæi et Fabricii iconibus illuſtrata," including thirty-ſeven explanatory plates, nearly all of which, however, had previouſly conſtituted the work of Sulzer.

Immediately after this, the publication of one of the moſt voluminous works on entomology that has been attempted was undertaken at Paris, by G. A. Olivier. Its title is conciſely "Entomologie, ou Hiſtoire naturelle des Inſectes;" from which we may infer, that its author propoſed to have treated on every claſs and order, and, in conformity with the firſt part, to have accompanied the whole with figures. Several faſciculi or numbers were publiſhed, amounting altogether to about three volumes; the whole of which are confined to the order coleoptera, and that even remains very incomplete. So far as it does proceed, the work is valuable. Olivier is the author of ſeveral other entomological writings. In the "Journal d'Hiſtoire Naturelle," he has a memoir, "Sur l'Utilité de l'etude des Inſectes, relativement à l'Agriculture et aux Arts." He is alſo the propoſer of a methodical diviſion of inſects, in the "Dictionnaire Entomologique." According to this plan, inſects are to be divided into four parts, namely, 1. Inſects with four wings; 2. Inſects with two wings and two wing-caſes; 3. Inſects with two wings; 4. Inſects without wings in either ſex. Theſe are ſubdivided into eight orders, the characters of which are taken from the mouth.

The inſects of Europe were further deſcribed by C. de Villers, in a ſmall work publiſhed at Lyons, in 1789, under the title of "Linnæi Entomologia," &c.; in which he profeſſes to avail himſelf of the works of Scopoli, Geoffroy, Degeer, Fabricius, and others. Paykull was at this time engaged alſo upon the inſects of Sweden, at leaſt on the coleopteræ; and this year he publiſhed his "Monagraphia Staphylinorum Sueciæ;" and which, a while after, was ſucceeded by two other tracts on the curculiones and the carabi, "Monagraphia Curculionum Sueciæ," and "Monagraphia Caraborum Sueciæ." But the moſt extenſive of the works of Paykull is his "Fauna Suecica," in three octavo volumes, printed at Upſal in 1799.

In the "Journal für die Entomologie," the name of Meyer occurs as the author of ſome remarks on the melolontha. Preyler, in the year 1790, publiſhed at Prague a "Verzeichniſs," or catalogue of the inſects of Bohemia. Quenſel is the author of a tract on the papilio, entitled, "Beſkrifningar öfer 8 nya Suenſka Dagfjärillar;" and alſo of another on noctua pruni, "Beſkrifning öfver en y Nattfjäril."

The firſt part of a conſiderable work, "The Natural Hiſtory of Britiſh Inſects by E. Donovan," appeared in the early part of the year 1792; and having obtained a favourable reception, has been continued in a courſe of monthly numbers from that period to the preſent time (1809). The deſign of this undertaking is to afford ſcientific and general deſcriptions, accompanied by appropriate coloured figures of every inſect diſcovered in this country; and ſo far as that deſirable object could be accompliſhed, in all their various ſtates of transformation. In its preſent form, the work conſiſts of fifteen volumes; the number of plates exceed 500, and theſe include an extenſive variety of ſpecies. Without incurring the charge of preſumption, the writer of this article believes he may be allowed to obſerve that the preſent conſtitutes the moſt copious work of its kind that has hitherto, or probably ever may be undertaken, as an elucidation of the entomology of Britain.

The inſects of Germany afforded materials for another entomological work of a local nature, commenced by Dr. G. W. F. Panzer, in 1793, under the title of "Faunæ Inſectorum Initia, oder Deutſchlands Inſecten;" and this was ſhortly after ſucceeded by his "Entomologia Germanica," &c.; both which are written in German and Latin, and are illuſtrated by plates. Dr. Smith's "Tour on the Continent in 1786-7," was publiſhed alſo in 1793; and this claims our particular mention, as it will be found to contain ſome curious obſervations reſpecting the inſects of the countries he viſited. About the ſame time, a French edition of Fueſsly's "Archiv der Inſektengeſchichte" made its appearance in quarto, with the original plates.

A valuable ſyſtematic paper, propoſing "a new arrangement of the papilios" by Mr. William Jones, occurs in the ſecond volume of the Tranſactions of the Linnæan Society, printed at London in 1794. The object of this communication is to point out, that the ſhape of the wings, which form a principal character with Linnæus in his diſtribution of this genus into families, though various at the firſt view, approach each other ſo gradually, that it is impoſſible to draw from them the diſtinguiſhing line between each family. The number of ſpecies known to Linnæus are eſtimated at rather more than 274, whereas the writer obſerves he had ſeen above 1000 in various cabinets, and about 400 more repreſented in various publications; and from an attentive examination of theſe is induced to offer the following amendments to the characters of each family, as defined by Linnæus. The latter author deſcribes the *Equites* as having "the upper wings longer from the poſterior angle to the point than to the baſe; and the antennæ often filiform:" this is corrected by ſaying, "the upper wings are longer from the poſterior angle to the point than to the baſe, occaſioned by having four nerves inſtead of three, viſible in every other family. The palpi frequently only a bruſh; under wings, with a connecting nerve in the centre, and without an abdominal groove."—*Heliconii.* "Wings narrow, entire, often naked, or deprived of ſcales; the upper wings long, the inferior ſhort." Linn. To this character is added, that the upper wings have "a connecting nerve in the centre, very ſlightly grooved to admit the abdomen, which is in general long, as are alſo the antennæ."—*Danai.* "Wings entire." Linn. Addition: "the under with a connecting nerve in the centre, and a deep abdominal groove; palpi projecting."—*Nymphales.* "Wings denticulated." Linn. Addition: "the under without a connecting nerve in the centre, and with a deep abdominal groove; palpi projected."—*Plebeii.* "Small, rurales; ſpots on the wings obſcure." Linn. Addition: "thorax and abdomen ſlender; under wings without a connecting nerve; antennæ clubbed:" and theſe are divided into two ſections, thoſe with long, weak, flexible tails; and thoſe without tails, and having the wings entire.—*Plebeii urbicolæ.* "Spots on the wings for the moſt part tranſparent." Linn. Theſe Mr. Jones divides into three families, according to the following character. * Thorax and abdomen ſhort, thick, or broad; under wings without a connecting nerve; antennæ uncinated, or crooked at the extremity. ** With upper wings pointed at the extremity, and long in proportion to their width. *** Upper wings leſs extended, and together with their under wings more rotund; their margins entire. There ſtill remain ſome papiliones, which do not rank with any diviſion above mentioned: theſe are generally of a large ſize, without an abdominal groove; have no connecting nerve; their antennæ generally acuminated; and the veins of both upper and under wings extending from their root to the extremity nearly in ſtraight lines. The author of this paper conſtitutes theſe as a new family, under the name of romani.

We ought not to diſmiſs our abſtract of the above paper, without obſerving that, from the great attention beſtowed on the papiliones by Mr. Jones, his opinion is of unqueſtionable authority. The ſpecies, which it is intimated the writer has ſeen in various cabinets to the amount of 1000, or perhaps more, have not to our own knowledge been obſerved merely: Mr. Jones has taken the trouble, for the gratification of himſelf and his ſcientific friends, to paint every ſpecies, and that in a very correct and elegant manner. The collection of drawings thus formed affords an unparalleled diſplay of this beautiful tribe of inſects.

In 1795, "The Papilios of Great Britain," a quarto work with plates, by William Lewin, was publiſhed in London. Whether it was the intention of the author to have proceeded further with this publication is uncertain: it finally terminated with the completion of the butterflies. About the ſame period the coleopterous inſects of Sweden were publiſhed in the language of that country, by D. E. Naezén, ſome part of whoſe works had, however, been produced to the public before that period. His books (for there are two) are entitled "Beſkrifning poa noagra, vid Umeoa fundene okände arter ibland Skalbaggarne," and "Beſkrifning poa noagra vid Umeoa fundne Inſecter, dels okande, dels foorut otydeligen bemarkte ochi Fauna Suecica ej uptagne." A Latin tract, printed in 1795, by D. H. Hoppe, contains an enumeration of the coleopterous inſects found in the invirons of Erlang, in Franconia; and in the ſame year, Latreille publiſhed his work, entitled, "Precis du Charactére des Genres." In this laſt-mentioned work, inſects are divided into two principal claſſes, namely, thoſe with wings, and thoſe without wings. The orders are coleopterès, orthoptères, hémiptères, neuropteres, lépidoptères, ſuceurs, thyſanoures, paraſites, acéphalés, entomoſtracés, cruſtacés, and myriapodes. An arrangement of the inſect tribes, in a manner ſomewhat different, occurs in "Tableau Methodique des Inſectes," by the ſame author. An important paper on the oeſtrus genus, by B. Clark, inſerted in the third volume of the Linnæan Society Tranſactions, is duly noticed under the article Bot. The laſt production we have to mention in the preſent year is a ſmall tract, accompanied by a coloured figure of an extremely beautiful and ſingularly formed beetle, in the cabinet of Mr. Francillon; a ſpecies of ſcarabæus, having the poſterior legs remarkable both for their length and thickneſs, and hence denominated the kangaroo beetle (ſcarabæus macropus). The inſect is preſumed to be a native of Potoſi, in South America.

The ſecond volume of "Catalogus Bibliothecæ Hiſtorico Naturalis, Joſephi Banks baroneti," &c. by J. Dryander, comprehending the entomological works of that invaluable library, iſſued from the preſs in 1796. From the claſſic manner in which each production is arranged in an appropriate department, according to its leading character, this work muſt be conſidered as forming in itſelf a valuable bibliothecal ſyſtem of entomological writers. As an aſſemblage of references, we cannot ſpeak too highly of its contents.

"The Natural Hiſtory of the rarer Lepidopterous Inſects of Georgia," in North America, forms a pleaſing acceſſion to our knowledge of thoſe particular ſpecies which it is the object of this work to elucidate. The number of inſects contained in the two coſtly volumes, of which the work conſiſts, amounts to about one hundred. Theſe conſtitute an ample ſelection of the larger kinds of the butterfly, ſphinx, and moth tribes, peculiar to that region. Each inſect is repreſented with its larva, pupa, and an example of one of the plants on which it is known to ſubſiſt. This work is written by Dr. J. E. Smith, from a ſeries of notes and drawings made by Mr. Abbot, an aſſiduous collector in North America; and beſides combining the practical information derived from the latter ſource, is rendered valuable by the numerous additional obſervations of the author. This work appeared in 1797.

Clairville, the author of a work on the inſects of Switzerland, publiſhed in 1798, propoſes to divide inſects into eight orders, ſomewhat after the manner of Linnæus, but to diſtinguiſh them under other names, and to denominate them claſſes inſtead of orders. The names he propoſes are elytropteres, dictyopterès, thleboptères, halterеptères, lepidopteres, hémiménoptères, rophoptères, and pododunères.

In the ſame year with the preceding, "Donovan's Natural Hiſtory of the Inſects of China" appeared in London. This is the only work dedicated to the diſplay of the entomological productions of that vaſt empire that has been publiſhed. The materials which conſtitute the baſis of this volume, and from which it was in a great meaſure compoſed, were obtained from the firſt and moſt authentic ſources; including examples of the inſects collected at the time of the embaſſy of lord Macartney, in addition to many others obtained from various cabinets of the higheſt celebrity, and the communications of friends. The work is embelliſhed with fifty coloured plates. A tranſlation of this publication has appeared on the continent in the French, and another in the German language.

The year 1800 was productive of ſeveral valuable works on the ſubject of entomology; in Sweden, Paykull this year publiſhed his "Fauna Suecica," a much admired publication, in three volumes octavo. Cuvier, with the aſſiſtance of

Duméril, brought forward in Paris his celebrated "Anatomie Comparée," a work which, however ill ſuited to the philoſophic taſte of our own country, is a production of very extraordinary merit. The organization of the various tribes of inſects is treated at great length in the lectures relating to invertebral animals. This work affords us alſo a new ſyſtematical arrangement, in which all inſects are divided into two principal ſections; thoſe with jaws, and thoſe without jaws. In the firſt of theſe orders are comprehended the gnathaptères, neuroptères, hymenopteres, coleopteres, and orthopteres; the ſecond, conſiſting of ſuch as are deſtitute of jaws, are, hemipteres, lepidopteres, dipteres, and apteres. The fifth volume of "Bibl. Hiſt. Nat. Bankſiana," the addenda of which contains ſome further mention of entomological writers, was alſo publiſhed in 1800. The laſt work that appeared in the preſent year was "Donovan's Inſects of India," a publication correſponding in ſize, and ſtyle of embelliſhment, with the "Inſects of China," and, like that work, embracing in a general, though ſcientific view, a comprehenſive diſplay of the more curious, rare, and ſplendid ſpecies peculiar to thoſe fertile regions, the entomology of which it is deſigned to explain. This work, as in the former inſtance, is conſtituted from the firſt ſources of original information. The more immediate intention is the elucidation of the entomological production of the Britiſh poſſeſſions in India; but it contains alſo a variety of inſects of the more beautiful kinds diſcovered in the interior of that vaſt continent, and in the iſlands ſituated in the Indian ſeas.

Lamarck's "Syſtême des Animaux ſans Vertèbres," printed at Paris in the 9th year of the revolution (1801), preſents a new mode of arrangement for inſects. Theſe its author propoſes to divide into three primary claſſes; namely, 1ſt, thoſe with mandibles and jaws; 2d, thoſe with mandibles and a kind of trunk; 3d, thoſe without mandibles, but having a trunk or ſucker. The firſt of theſe claſſes contains the coleopteres, orthopteres, and neuropteres; the ſecond is confined to the ſingle order hymenopteres; and the third includes the lepidopteres, hemipteres, dipteres, and apteres. The coleopteræ are ſub-divided into three families, according to the number of joints in the feet, as thoſe with five joints in all the feet; thoſe with five joints in each the four anterior feet, and four in thoſe of the poſterior pair; and thoſe with only three joints in all the feet. Moſt of the Linnæan aptera are removed to another claſs preceding the inſect tribe; the only Linnæan genus of aptera, admitted by Lamarck into his order apteres, is the pulex.

The publication of "Marſham's Entomologia Britannica" commenced in the year 1802, with the production of the volume in which the coleopteræ are deſcribed. As the outline of the arrangement adopted by this author is ſtrictly Linnæan, thoſe after the manner of that naturaliſt conſtitute the firſt ſeries, and are to be ſucceeded progreſſively by the hemiptera, lepidoptera, and other remaining tribes. For the purpoſe of this continuation very ample materials are provided. Mr. Marſham, whoſe abilities as an entomologiſt are well known, has devoted many years of his life to this laudable object: his collection of Britiſh inſects is of the firſt claſs, and his manuſcripts of the moſt valuable kind. The completion of this work muſt be therefore anticipated as a deſirable event. The merit of the firſt volume is acknowledged, and ſhould the future part appear with correſponding excellence, we could not heſitate in pronouncing it one of the moſt important works of its kind that has appeared.

Kirby's "Apum Angliæ" was alſo printed in 1802. This work contains much curious information relative to the bees of this country; a path of entomology in which its ingenious author has trod with great ſucceſs. The Linnæan genus apis Mr. Kirby conceives it neceſſary to divide into two genera, to one of which he retained the original name, the other he terms melitta, and under both genera he deſcribes many ſpecies, ſome of which are noticed for the firſt time in this intereſting work. Latreille, who has written on the Linnæan genus apis, and is eſteemed an entomologiſt of ability, pronounces this "un bon travail." The ninth volume of the Tranſactions of the Linnæan Society contains an ingenious paper on the apian genus of Herbſt by Kirby; and there are alſo two or three other papers diſperſed in thoſe volumes, by the ſame writer, well deſerving of attention.

The contents of the ſecond and third volumes of Turton's tranſlation of the Linnæan "Syſtema Naturæ a Gmelin," relate entirely to entomology. This work deſerves further obſervation. The editor does not, in treating of inſects, confine himſelf to the direct tranſlation of his author; he introduces ſome commendable improvements in the arrangement after the Fabrician manner; and he beſides incorporates from other entomological works of credit, publiſhed ſince the time of Gmelin, whatever prominent traits of information he conceived calculated to amend the original work. We may eaſily perceive that Dr. Turton has availed himſelf of the Fabrician "Entomologia Syſtematica" to a greater extent than Gmelin, and has by this means rendered more eſſential ſervice to the Engliſh reader.

The pages of "Donovan's Tour through South Wales and Monmouthſhire," lately publiſhed, are interſperſed with obſervations on the various natural productions of the intereſting tract of country immediately under conſideration. Thoſe digreſſions, from objects of more general moment, if ſuch the reader be inclined to deem them, we at leaſt may preſume to think important; and ſo far as theſe relate to the ſcience of entomology in particular, conceive they may, without impropriety, be adverted to in this place.

"Donovan's Inſects of New Holland," including alſo thoſe of New Zealand, New Guinea, and the ſeveral iſlands in the Great Southern and Pacific ocean: this accords with the "Inſects of India," already mentioned, being in quarto, with ſcientific and general deſcriptions, and in having the ſimilar accompaniments of accurately coloured plates. Of this work it will be alone ſufficient to obſerve, that through the diſtinguiſhed favour beſtowed on the deſign, the author was allowed to enrich his volume with delineations of thoſe uncommon inſects collected during the voyage of captain Cook, by thoſe celebrated naturaliſts who accompanied that circumnavigator round the world, and which appear for the firſt time in this work.

The ſixth volume of "Shaw's General Zoology" is offered as an illuſtration of the ſcience of entomology. The work profeſſes only to elucidate the Linnæan genera of inſects, with the hiſtory of the principal ſpecies. This being the intention of its ingenious author, the work is comprized in a very moderate compaſs. The plates are rather numerous, and in general remarkable for the neatneſs of engraving. Theſe, however, are not original, being compiled from the plates of Seba, Roſel, Swammerdam, Barbut, and others. The "Naturaliſt's Miſcellany" contains a variety of coloured figures of the more ſplendid kinds of exotic inſects, with deſcriptions extremely ſuitable to the general claſs of readers, for whoſe purpoſe they are deſigned.

Laſtly, we ought to mention the work of Coquebert, entitled "Illuſtratio iconographia," recently publiſhed in France: the late entomological tracts of Olivier and Latreille, the "Faune Pariſienne" of Walcknaer, and the papers on different tribes of inſects inſerted in the Tranſactions of the Linnæan Society of London; the Societé d'Hiſtoire Naturelle of Paris, and thoſe of various other learned inſtitutions, through the medium of which they are diſtributed to public obſervation.

Our review of entomological writings is at length drawn to concluſion. In its progreſs we have endeavoured to include every work of importance in this department of ſcience, that has appeared. To what has been advanced reſpecting theſe, nothing material can be added in this place; it was our aim, throughout the preſent inquiry, to point out the leading character of each work, while paſſing under immediate conſideration, and for this reaſon we ſhall abſtain from offering any general comments. By connecting the whole in the order of time in which they were produced, our object has been to ſhow at one glance, ſo far at leaſt as our ſlight compariſons would permit, thoſe eſſential reſpects in which each has materially improved upon his predeceſſor; and by that means mark the progreſſive advancement made in the ſcience with ſome preciſion. We ſhall finally diſmiſs this part of our ſubject with obſerving, that it is poſſible ſome few works of real worth may have eſcaped our mention; the number of theſe, however, we are perſuaded, muſt be very inconſiderable, and confined to ſuch as have recently appeared in countries remote from Britain.

Claſſification.

It will be obſerved, from the preceding obſervations, that naturaliſts entertain very diſtinct opinions as to the principles on which the claſſification of inſects ought to be founded. This diverſity of idea ariſes from the different views under which they have been conſidered. Valiſneri divides inſects into four claſſes, according to the places in which they live, as plants, in water, in the earth, or upon the bodies of other animals. Agricola into three, namely, thoſe which walk, fly, and ſwim; Frenzius, into flying inſects, aquatic inſects, and terreſtrial or creeping inſects. Swammerdam diſtributes them into claſſes from their appearance in the ſtates preceding their final transformation, without particular regard to the laſt or complete ſtate. In this reſpect Swammerdam is followed by Ray, whoſe two primary claſſes are, of thoſe which undergo transformation, and thoſe which do not; and his orders are determined from their metamorphoſes, and the number of their feet. Liſter has given a ſyſtem founded on the figure of the egg in which the inſect is incloſed, and the number of the feet. The difference obſervable in the texture, and alſo in the number of the wings, form the diſtinctions of the primary diviſions of Linnæus. And laſtly, the principal characters upon which inſects are diſtributed, in the arrangement of Fabricius, is taken from the ſtructure of the mouth. Each of the ſyſtems founded on thoſe diſſimilar characters have gained admirers. The characters of the Linnæan and Fabrician ſyſtems appear the beſt, and are moſt univerſally approved.

General obſervations on Inſects.

Inſects are a race of animals deſtitute of internal bones, in which reſpect they accord with a very extenſive number of natural families in the lower orders of animated beings. Their bodies are kept in a ſtate of moiſture by the circulation of lymphatic tranſparent juices inſtead of red blood, and in this particular agree with the worm tribe. They have no diſtinct heart, external ears, openings at the noſe, or noſtrils, nor teeth in the mouth; and ſome aſſert that they are deſtitute of voice. An inſect is divided into ſegments, or joints, and covered externally with a tough or bony ſkin, which is either naked or clothed with down. The head is furniſhed with moveable antennæ, and the body with feet.

Theſe animals are deſtitute of viſible external organs of breathing at the mouth, their reſpiration is performed through the lateral apertures, or ſpiracles of the body and thorax.

They have two eyes, in which reſpect they agree with the larger tribe of animals: they have no eyelids, and their eyes are rarely placed on a pedicle; the diopſis is an exception.

The antennæ are ſituated on the head before the eyes; and are compoſed of an indefinite number of articulations; in genuine inſects, the antennæ never exceed two. The cancri have a greater number, and many of the Linnæan apteræ have none.

The feelers are articulated, moveable, variable in number from two to ſix, and are affixed contiguous to the mouth.

The mouth is uſually ſituated beneath the head.

The jaws are diſpoſed tranſverſely in the head, and move laterally, by which means they are diſtinguiſhed from moſt other animals.

The trunk is placed between the head and the abdomen.

The abdomen is uſually annulated with five ſegments, and is ſometimes armed at the end with a ſting.

The legs are uſually ſix in number, and are attached to the trunk. Each leg conſiſts of three diſtinct diviſions, the thigh, ſhank, and feet.

The wings are either two or four; ſome of thoſe with two wings only are protected by a ſhelly covering, as in the coleopteræ.

Inſects are oviparous; depoſit their eggs in an impregnated ſtate in general, and do not brood over them, or their young. Moſt inſects undergo a triple transformation, the egg producing a grub or larva, which becomes, when full grown, a pupa, and the later producing the perfect fly. The ſexes are male and female; there are alſo neuters in ſome ſpecies devoted to labour for the former. Inſects caſt their ſkins, and therein agree with reptiles. They are ſaid to inhabit thoſe plants on which they uſually feed.

Deſcription of the component parts of Inſects.

The external parts of which inſects conſiſt are divided into four principal ſections, the head, trunk, abdomen, and members, each of which require to be ſeparately conſidered.

Caput, or *Head.*—Under this term is included the firſt, or principal organ, the head, properly ſo denominated in its collective form. This part is ſuppoſed to be the principal ſeat of the ſenſes, as in all others of the larger and apparently more perfect animals. Internally it contains the medullary ſubſtance or brain; its exterior characters are, the mouth, eyes, ſtemmata, antennæ, front, vertex, and throat.

In ſome inſects the head is very large in compariſon with their body. The proportion between the head and body is not the ſame in all inſects, even in the different ſtages of growth or transformation. In the caterpillars, which have this part horny, it is generally ſmall before they moult, or change their ſkin, and becomes larger after each moulting.

This part is almoſt conſtantly diſtinct from the thorax: in the coleoptera it is connected cloſe to the latter: the hemiptera offer many examples in which the head is ſlightly attached, as in the genera blatta, acheta, phaſma, mantis, &c.: in the lepidoptera order the head is not always very intimately ſituated to the thorax; there is a ſmall interval ſometimes between which the articulation of the neck may be ſeen, when the head is inclined downward. The ſucceeding order, neuroptera, afford numberleſs inſtances of the head being placed upon a ſlender ligamentous pedicle at a diſtance from the thorax: in hymenoptera and diptera the head is rather remote, ſometimes being placed on a ſmall tubercle in the anterior part of the thorax; and in the laſt, or apterous order of Linnæan inſects, ſeveral of the genera are diſtinguiſhed by having the head and thorax confounded with each other, as in ſcorpio, aranea, monoculus, &c.

The connection between the head and thorax in inſects ſubſiſts by one of two modes of articulation; the firſt, in which the point of contact is ſolid, and the motion depends upon the ſhape of this part, or another in which the articulation is formed by a ligament. In the articulation of the head by the contact of the ſolid parts, the head has commonly, at the part anſwering to the neck, one or two ſmooth tubercles, which are received into correſpondent cavities on the anterior part of the thorax. This is exemplified in the genera ſcarabæus, lucanus, cerambyx, and moſt other coleoptera, and which hence have the power of moving the head backward or forward, and thus of directing the mouth downward. Another mode of ſolid articulation takes place when the poſterior part of the head is rounded, and turns on its axis in a correſpondent ſocket on the anterior part of the thorax, as in the brentus, &c. The axis of motion is then in the centre of the joint, and the mouth of the inſect can be directed either upward or downward, or to the right and left. A third ſort of articulation occurs when the head is truncated behind, and joins by a flat ſurface either to a tubercle of the thorax or to another flat and correſponding ſurface, as is ſeen in many of the hymenoptera and diptera. In ſome kinds of the Fabrician attelabi, this ſolid articulation is accompliſhed by another means: the head of theſe inſects terminate behind in a round tubercle, which is received into a correſpondent cavity of the thorax: the inferior edge of this cavity is notched, and thus confines the motion of the head to one direction.

The ligamentous connection of the head and thorax is ſhewn in the blatta, forficula, mantis, and ſeveral of the neuroptera. In this mode of articulation, the motion of the head is very extenſive, and confined only towards the back, in which direction it is oppoſed by the projection of the back. The muſcles which move the head are ſituated within the thorax: the membranes or ligaments extend from the anterior part of the collar to the ſurface of the occipital foramen.

Brain, or Medullary Subſtance.—According to the "Fundamenta Entomologiæ," it was the idea of Linnæus, that inſects have no brain in the head; an opinion often repeated ſince his time, but which, from the obſervations of the ableſt phyſiologiſts of the preſent period, proves to be unfounded. Linnæus does not deny the exiſtence of a medullary thread in this part of inſects, but ſtates that he never could diſcover it to be organiſed; and hence, he ſays, the hippoboſca equina, or horſe-fly, will run, live, nay even form an union with the oppoſite ſex, after being deprived of its head, to ſay nothing of many others, which are capable of living for a conſiderable while in a decapitated condition. From the anatomical inveſtigations of Cuvier it is, nevertheleſs, ſufficiently obvious, that independently of a nervous medullary thread, inſects have a brain diſtinctly organiſed, from which this thread and other nerves ariſe, and that its ſeat is in the head, as in the more noble tribe of animals. The exiſtence of a true brain in inſects was believed by many writers before the time of Linnæus, and by ſome after; but, generally ſpeaking, the opinion of this celebrated naturaliſt was aſſented to, and enquiry ceaſed, till its conſideration was revived by Fabricius, and the phyſiologiſts of France, the moſt diſtinguiſhed of whom is Cuvier, and from the reſult of their obſervations it may be affirmed, that inſects, as well as moſt other animals, have a genuine brain.

Fabricius is reputed to be the firſt who diſcovered the true brain in inſects. That Fabricius affirms the fact, and that as an entomologiſt his aſſertion was ſucceſsfully oppoſed to the opinion of Linnæus in this reſpect, is not to be denied, yet the merit of diſcovery is by no means due to this writer. His obſervations on the brain, the organs of hearing, and other ſenſations of inſects, were made chiefly on the lobſter or cray-fiſh, animals of the cruſtaceous kind, and which, though in ſome reſpects analogous, we do not admit to be of the inſect race. But if they were, can we have ſo entirely forgotten the anatomical inveſtigations of cancer aſtacus by Roeſel, as to allow Fabricius the credit of diſcovering thoſe very organs which he deſcribes many years before; and if he really obſerved thoſe organs in genuine inſects, can we overlook the laborious anatomical enquiries of Swammerdam, or the minute reſearches of Lyonet, in which the exiſtence of ſuch an organ is rendered manifeſt, with no other view than to award the merit of its diſcovery to Fabricius?

No phyſiologiſt whatever has purſued this intereſting ſubject of enquiry ſo far as Cuvier. This attentive and ſkilful obſerver examined a conſiderable number of the different tribes of inſects, in order to aſcertain their internal organization, and has eſtabliſhed, beyond diſpute, if any doubt could ſtill remain, that inſects have a brain in the head. From Cuvier we alſo learn that the brain is not conſtantly of the ſame ſtructure in all inſects; in ſome tribes this organ conſiſts of one lobe, in others of two, and in others again of four; and the nerves ariſing from them differ alſo very materially in different families, and ſometimes even in ſpecies. But beſides this diſſimilarity, there is another circumſtance infinitely more remarkable, the form of the brain and medullary nerves in certain inſects, are aſcertained to undergo a conſiderable change, as well as the external organs, in paſſing from the larvæ to the perfect ſtate. The moſt extraordinary of theſe deſerve notice, and the circumſtance being ſtated may ſtimulate others, perhaps, to a farther enquiry, in the reſult of which, it is apprehended, a ſimilar change, will be obſerved, in a far greater number of the inſect race than may be at preſent conceived.

Brain in Coleopterous Inſects.—The larva of a large beetle, common in Europe, and known by naturaliſts under the name of ſcarabæus naſicornis, affords a favourable opportunity for the aſcertainment of this fact; it is of a large ſize, and the change it undergoes in paſſing to the winged ſtate is very conſiderable. The brain in this larva is ſituated under the great ſcale which covers the head, immediately above the origin of the œſophagus. It conſiſts of two approximate lobes, which are very diſtinct at the front and back part. Four nerves ariſe from the anterior part, two on each ſide, which are loſt in the cirri and parietes of the mouth, one pair of nerves ariſes alſo from the lateral and ſomewhat poſterior part of the brain, which, embracing the œſophagus, proceeds below to form a nervous cord; and another pair is produced from the lower ſurface of the brain. In the perfect inſect, the nervous cord preſents a very conſpicuous difference; in the larva there is only a ſingle ganglion, but the perfect inſect has ſeveral, and which are very diſtinct. The firſt is ſituated above the condyle: it proceeds from the two poſterior filaments of the brain, and is diſtributed to the muſcles which move the head on the corſelet. Its poſterior part produces two filaments, which paſs into the breaſt, where they unite towards the middle, and form a triangular ganglion, from the ſides of which three pairs of nerves ariſe, and are diſtributed to the muſcles. Its poſterior angle detaches two parallel nerves which proceed into the breaſt, where they form a third and fourth ganglion, ſituated very near each other, and apparently divided into two lobes by a longitudinal furrow. All the other nerves of the body proceed from theſe two ganglia, by an irradiation preciſely in the ſame manner as in the larva.

The nerves in the larva of the ſtag beetle (lucanus cervus) differ greatly from that of the foregoing inſect. The brain conſiſts of two contiguous and almoſt ſpherical lobes, which produce four nerves anteriorly; two beneath and two behind, which latter form a collar round the œſophagus, and uniting underneath compoſe the nervous cord of the body. The cord is formed of eight ganglia, and extends to the ninth ring of the body. In the perfect ſtate the brain conſiſts likewiſe of two approximate lobes of a ſpherical form. There are alſo two ganglia on the lateral parts of the brain, which are almoſt as large as each of the lobes: in form they reſemble a pear, and reſt on the brain by their baſe: the two anterior pairs of nerves ariſing from the brain terminate in the palpi and other parts of the mouth. The brain produces alſo two very long and ſlender nerves behind, and the diſpoſition of the nerves ariſing from the various parts differ very much from thoſe obſervable in the larva.

The nervous ſyſtem of the larva of hydrophilus piceus, or great water beetle (dytiſcus, Linn.), will ſerve to illuſtrate thoſe of an extenſive number of other coleopterous inſects, ſuch as the larva of cerambyces, dytiſci, carabi, ſtaphylini, &c. Some little variation will be found, but the analogy is very conſpicuous. The brain in the larva of this inſect is ſituated in the head above the origin of the œſophagus; it is formed of two lobes, which lie very cloſe together. From its anterior part it detaches ſome filaments to the palpi, the antennæ, and the parietes of the mouth. Its lateral parts produce two cords, which ſurround the œſophagus, and which are the origin of the nervous cord ſituated inferiorly. The chief nervous cord is compoſed of ten ganglia, each of which produces three pairs of nerves, which are loſt in the muſcles of the abdomen. In the perfect inſect the brain conſiſts of two ſpherical bulbs, which are cloſely united. The lateral parts give origin to the optic nerves. The anterior part of the brain detaches ſome filaments intended for the parietes of the mouth. In the ſame place is alſo a ſmall ſpherical ganglion, which ſeems to belong to the recurrent nerve that accompanies the œſophagus. The brain in the larva of dytiſcus marginalis is different from that in the larva of hydrophilus piceus, although thoſe two inſects are ſo cloſely allied in genera; in the latter it is ſpherical, and conſiſts of a ſingle lobe, it is ſituated in the head above the origin of the œſophagus: its anterior part produces ſome filaments for the mouth, and its lateral parts the two optic nerves: the latter are compoſed of two parts, which are very diſtinct in form. That portion next to the brain is of an oval figure, pointed at the extremity which joins the brain, the other extremity is rounded, and produces a ſlender nerve, which paſſes directly to the eye.

Hemiptera.—The ſtructure of the nervous ſyſtem in the larvæ of hemipterous inſects does not often differ very ſenſibly, it is ſaid, from that which is exhibited in the perfect inſect to which they reſpectively belong. But the ſmall number of this tribe already examined do not authoriſe us to ſpeak on this ſubject with much confidence. A conſiderable difference prevails in this reſpect between the perfect inſects of ſome oppoſite genera, as appears from thoſe which Cuvier deſcribes. In the cock-roach, blatta americana, the brain is compoſed of two lobes, ſeparated by a very diſtinct notch anteriorly. The optic nerves ariſe on the ſides, and its anterior part detaches ſome filaments to the parietes of the mouth, and to the inſtruments of manducation. The nervous cords, which form the medulla, ariſe from its inferior ſurface. In the great green locuſt (gryllus viridiſſimus) the brain is ſituated in the head above the œſophagus; it conſiſts of two lobes, which are pyriform, united at their baſe, and prolonged at their other extremity into an optic nerve for the eye of each ſide. The anterior part alſo produces two nerves of a pyramidal form, the baſe of which reſts upon the brain. The brain of the mole-cricket (acheta gryllo-talpa) is compoſed of two rounded lobes, which are particularly diſtinct at the poſterior part. The nervous ſyſtem of the water ſcorpion (nepa cinerea) is different. This conſiſts of three ganglia, the firſt of which (properly the brain) is ſituated in the head. It is formed of two approximate pyriform lobes, which touch each other at the baſe, while their ſummits are directed obliquely forward towards the eyes in which they terminate: the middle and anterior part of theſe lobes alſo produce filaments for the parts of the mouth; the third, which is more voluminous than the brain, lies near the baſe of the ſecond pair of legs.

Lepidoptera.—The nervous ſyſtem of caterpillars, or lepidopterous inſects in the ſtate of larvæ, conſiſts of a ſeries of thirteen principal ganglia, which furniſh filaments to all the other parts of the body. The firſt of theſe ganglia is what may properly be conſidered as the brain: it is ſituated in the cavity of the head above the œſophagus, and conſiſts of two round tubercles, which are concave beneath, and correſpond to the convexity of the œſophagus. This ganglion communicates with the reſt of the nervous cord by two thick filaments, which embrace the œſophagus, and which are united below it to the anterior and lateral parts of the next ganglion; and it beſides produces eight pairs of nerves. The firſt partly unites with other filaments; produces ſome for the œſophagus, and forms ſeveral remarkable ganglia below the lower lip. The largeſt and moſt poſterior, which Lyonet has named the firſt frontal ganglion, is prolonged behind into a thick recurrent nerve, which is continued the whole length of the body contiguous to the back. The ſecond pair of the brain appears chiefly intended for the antennæ, though it furniſhes ſeveral filaments to the neighbouring parts, and the others for the more remote portions of the body. Theſe obſervations are from Lyonet, and relate principally to the larva of the goat moth (phalæna coſſus of Linnæus.) Few of the lepidopterous inſects in the winged ſtate have yet been examined for the purpoſe of aſcertaining the ſtructure of the brain. In phalæna diſpar this organ is almoſt ſpherical; there is, however, a longitunal furrow on the middle line. Its anterior part produces ſome exceeding ſlender nerves. There are alſo two large optic nerves on the ſides which proceed into the concavity of the eye, where they terminate by a bulb, from whence ariſe a great number of filaments.

Neuroptera.—In the larva of the lion-ant, (myrmellon formicarius) the nervous medulla, proceeding from the brain in the head, conſiſts firſt of two ganglia, which are compoſed of two lobes ſituated cloſe together, and are placed in the thorax; the remainder of the nervous medulla, conſiſting of eight ganglia placed in very cloſe ſeries, and each formed of two lobes, is contained in the abdomen. The larva of the ephemeræ has eleven ganglia, excluſive of the brain, which furniſhes two large optic nerves. The larvæ of the libellulæ, or dragon flies, have a ſmall two-lobed brain, which produces optic nerves, larger or ſmaller in different ſpecies.

The Fabrician genus æſhna has the largeſt. The reſt of the nervous ſyſtem forms a ſeries of ganglia of different ſizes. In the æſhna the thorax contains ſix, the two laſt of which are the largeſt, and there are ſeven ſmall and equal ganglia in the abdomen. In the winged ſtate the brain is formed of two very ſmall lobes, and the optic nerves are dilated into the form of two very large plates, which have the figure of a kidney, and which is ſpread upon all the inner ſurface of the eye next the head. The remainder of their medullary cord is exceedingly ſlender, and furniſhed with twelve or thirteen ſmall ganglia, the laſt of which is, as uſual, connected with the organs of generation.

Hymenoptera.—The brain in the larvæ of ſome kinds of tenthredines, which have the head large, is broad and ſhort, and ſeems to conſiſt of four bulbs of equal magnitude, and the form of which is nearly ſpherical; the two external ones ſerve as the baſe of the optic nerves, which are ſlender, and enlarge a little at their other extremity. The firſt ganglion is produced by two very ſmall nerves, which ariſe from the inferior ſurface of the brain, and which, after having embraced the œſophagus, unite under the firſt ring of the body; it furniſhes filaments to the muſcles of the feet, and terminates poſteriorly in two other nerves, which, at the diſtance of one line, produce a ſecond ganglion, and ſo on in ſucceſſion: the nervous cord is in this manner formed of eleven ganglia, excluſive of the brain: all the ganglia are of a roundiſh form, and diminiſh in thickneſs as they recede from the head. The brain of one of the hymenopterous tribe in the winged ſtate (the common bee) is rather ſmall, and is divided into four lobes. It produces the nerves which are diſtributed to the different parts of the mouth, and the two large optic nerves which are dilated, and applied behind each eye, as in the libellulæ. There are afterwards ſeven ganglia, three of which are in the thorax and four in the abdomen. The nerves of the laſt chiefly ſupply the ſexual organs.

Diptera.—The nerves of the larvæ, in ſome of the Linnæan muſcæ, as m. chamæleon, &c. (ſtratiomys, Fabr.) have ſome reſemblance to thoſe of the larva of ſcarabæus naſicornis. The brain is formed of two lobes placed cloſe together and almoſt ſpherical; it is ſituated above the œſophagus, on a level with the ſecond ring of the body. A number of ſmall nervous filaments ariſes from its anterior part, and they are diſtributed to various parts of the mouth. The poſterior part of theſe two lobes ſends forth two thick branches, which embrace the œſophagus, and form the origin of the nervous medulla. This nervous cord is very ſhort, and in diameter one half leſs than that of the brain. It conſiſts of eleven ganglia placed very near each other, each of which produces one pair of nerves.

A more ſingular appearance is exhibited in the ſtructure of the nervous ſyſtem of muſca putris than that juſt deſcribed. The brain is ſituated immediately above the origin of the œſophagus behind the head; it is very large in proportion to the reſt of the body. The anterior part is notched, poſterior rounded, and appears altogether as if formed of two lobes. A pair of nerves ariſes from the anterior part of the brain, proceeds forward, and is diſtributed to the mouth. Theſe nerves become conſpicuouſly large previouſly to diſtribution. Poſteriorly the brain preſents an aperture which affords a paſſage for the œſophagus: the nervous part, ſituated at the ſides, may be regarded as cords which produce the medulla, and all below the œſophagus as the medulla itſelf.

Muſca tenax (Linn.) in the perfect ſtate has a ſmall brain, formed of two lobes, which are ſituated very near together, but diſtinguiſhed by a longitudinal furrow; the anterior part produces a large nerve, which is afterwards diſtributed to the antennæ and the proboſcis. In aſilus crabroniformis is a ſingle cord uniting the abdominal ganglia, which are ſix in number. The brain itſelf is ſimilar to that of the ſyrphus (as in muſca inanis, &c.) but the bulbs formed by the optic nerves are ſtill broader in proportion to the extent of the eyes they have to inveſt.

Aptera.—In the great centipede, ſcolopendra morſitans, the brain has a very ſingular form: the two lobes of which it is compoſed are almoſt ſpherical; the optic nerve is produced laterally and is very ſhort. The filaments are four in number, but two nerves ariſe anteriorly which are ſo very thick, that they appear part of the brain, to which they are equal in diameter. Theſe nerves are particularly intended for the antennæ, into which we obſerve them enter. The two cords which embrace the œſophagus proceed directly downward, and form a large ganglion at the union of the firſt ring with the head. The firſt ganglion produces two nerves poſteriorly, and ſeveral towards the ſides. A ganglion, preciſely of the ſame ſhape, is placed above each of the articulations: thus there are in all twenty-four very diſtinct ganglia in this inſect, from each of which are detached three pairs of nerves.

Mouth.—In order to afford ſome idea of the amazing difference that prevails in the ſtructure of the ſeveral parts or organs which conſtitute the mouth, it will be only requiſite to obſerve that the claſſification of all inſects, in the Fabrician ſyſtem, is founded on this character. There are ten principal parts of which the mouth conſiſts; and it is from the relative proportion of each, from the diſſimilarity in the form, poſition, variation in number, or occaſional peculiarities, that the moſt permanent characters are deduced. Theſe parts have one diſadvantage: they are generally ſmall, and from this circumſtance have not been ſo univerſally adopted in the arrangement of inſects as they would otherwiſe. Without, however, beſtowing ſome little attention to theſe organs, it is impoſſible to diſtribute inſects into their natural order with any great degree of certainty.

The organs of the mouth were ſlightly regarded by Linnæus; and to this cauſe alone we may attribute ſome few ſerious errors in the works of that naturaliſt. The parts he deſcribes are the roſtrum (or proboſcis), maxillæ, lingua, and labium ſuperius. Some of theſe are not ſufficiently diſcriminated; his roſtrum and proboſcis are not different; the maxillæ are confounded with the mandibulæ; and the labium ſuperius is not, as the expreſſion implies, the upper lip of the inſect, this latter part being ſituated under it. Fabricius defines theſe parts with more preciſion, as he derives his eſſential characters from them. In the arrangement of Olivier, in the works of Latreille, and moſt other modern writers on entomology, the eſſential characters are eſtabliſhed chiefly on the peculiarities of theſe organs.

The ten principal parts of which the mouth conſiſts are the following.

Labium ſuperius, or upper lip: a tranſverſe, ſoft, moveable piece of a coriaceous or membranaceous nature, known from its ſituation at the anterior or upper part of the mouth. This part is very diſtinct in many of the coleoptera, and in the gryllus, apis, and ſome other genera. Linnæus ſometimes confounds the upper lip with the clypeus or ſhield of the head; and ſimilar inſtances occur in the works of Fabricius. Theſe two parts may be diſtinguiſhed by one invariable character; the clypeus is fixed, and forms a portion of the head; the upper lip is moveable.

Labium inferius: the piece which terminates the mouth beneath, and which is ſometimes lengthened, ſo as to form the inſtrument called ligula. It is ſoft, flexible, uſually bifid, and has the poſterior pair of feelers placed at the baſe.

Mandibulæ, mandibles: two hard pieces, in ſubſtance reſembling horn, which are placed one at each ſide of the mouth, below the upper lip. Theſe have a lateral motion, while the upper and lower lip move up and down, as in other animals. Theſe differ from the maxillæ, with which they are ſometimes confounded, by not having any of the palpi or feelers attached to them. In rapacious inſects, theſe are larger and more powerful than in thoſe which perforate wood; and the latter again have ſtronger mandibles than inſects which feed only on herbage or leaves.

Maxillæ: two ſmall pieces of a ſomewhat membranaceous conſiſtency, and in figure different from the mandibles. Theſe are commonly indented at the extremity, and nearly all ciliated at the inner edge. They are placed under the mandibles, and above the lower lip; their motion is lateral. In thoſe inſects which have more than one pair of feelers, the poſterior ones take their origin from the ſides of the maxillæ.

Galeæ.—Shields of the mouth, two membranaceous appendages, uſually of a large ſize and cylindrical form, placed one on each ſide, at the exterior part of the jaw, and which cover and protect the organs of the mouth, conjointly with the lips. The galeæ are inſerted at the back of the jaws, as is well exemplified in the gryllus tribe.

Organs of Taſte.

Theſe appertaining of courſe, like the foregoing, to the mouth, and of which they conſtitute the moſt material part, admit of conſiderable variety in their formation, and in ſome particular tribes differ ſo greatly as to have obtained diſtinct names in the works of entomologiſts, according to their preciſe form; ſuch, for example, as ligula, lingua, roſtrum, proboſcis, and hauſtellum.

Ligula.—This is the part conſidered by many authors as the lower lip; its ſituation is immediately under the jaws; and it conſiſts of a ſingle piece, which is of a ſoft texture, often bifid, and, if attentively examined at the baſe, will be found of a horny ſubſtance.

In the coleoptera, and ſome of the hemiptera, as the blatta, phaſma, gryllus, &c. this tongue terminates at the point in a membranaceous ſubſtance: its form is extremely various in the different genera. The hymenoptera and ſome neuroptera have the tongue or ligula ſituated in the ſame manner; but it is in theſe concave, and is frequently prolonged into a ſort of proboſcis, which ſometimes exceeds the length of the whole body. It is membranaceous, but of a ſoft and ſpongy texture, and well ſuited for receiving the impreſſions of taſte. This kind of tongue is extremely well exemplified in the bee.

Lingua: tongue, the involuted tubular organ which conſtitutes the whole mouth in lepidopterous inſects. This is of a ſetaceous form, and either very long, as in the papilio and ſphinx genera, or ſhort, as in moſt of the bombyces and other moths. It conſiſts of two filamentous pieces, which are externally convex, concave within, and connected longitudinally by a ſuture along the middle above and beneath. Theſe in uniting form a cylinder, through which the nectareous juices of the flowers on which theſe inſects ſubſiſt are drawn up with facility. Theſe two pieces are not very cloſely united, and may be ſeparated by means of a needle point. When the inſect takes its food, this tube is exſerted; at other times it is rolled up ſpirally between the palpi.

A curious circumſtance is mentioned by Degeer, relative to the tongue of the butterfly. Having cut off the tongue of a papilio antiopa, almoſt as ſoon as it was emancipated from the chryſalis, it moved and rolled itſelf up at intervals for a conſiderable time: an hour after it had been cut off it repeated the ſame motions, recommencing them every time it was touched. It was obſerved that the ſame effect did not follow, if the butterfly had been liberated from the chryſalis for a few days.

Roſtrum, or beak: the part which forms the mouth in many of the hemipterous order of inſects. This inſtrument is moveable, articulated, and bent under the breaſt. Within this beak is hollow, and contains, as in a ſheath, three or more very fine and delicate briſtles, the points of which theſe inſects introduce into the body of the animal, or ſubſtance of the plants, from which they draw nouriſhment. The roſtrum is conſpicuous in the genera cicada, nepa, and cimex.

Proboſcis.—The trunk is inſerted in place of the mouth, in moſt dipterous inſects. It is rather fleſhy, retractile, of a ſingle piece, and often cylindrical; the end forming two lips, which are of a ſoft ſubſtance, and from the delicacy of their teguments muſt poſſeſs the faculty of taſte in a very high degree.

Hauſtellum.—Formed of two or more very ſmall and delicate filaments, incloſed in a ſheath of two valves.

Lingua, roſtrum, and proboſcis, are Linnæan terms: the firſt is adopted according to the definition of that ſyſtem; the two latter are ſynonymous with Linnæus. Ligula is a Fabrician expreſſion, indicating the lower lip.

Palpi.—Feelers. Theſe are the ſmall, moveable, filiform organs, or appendages, placed at each ſide the mouth in the generality of inſects. In ſome reſpects they reſemble the antennæ, but are more diſtinctly articulated. They vary in number in different inſects, being either two, four, or ſix, and are commonly inſerted at each ſide the exterior part of the jaw. In thoſe which have only one pair, they are uſually ſituated on the upper lip; when two or more, the poſterior ones are generally on the lower lip; and in ſome inſects furniſhed with a ſucking trunk, they are oftentimes found inſerted at each ſide of that organ. Theſe feelers are compoſed of ſeveral joints, the number of which vary. Like the antennæ, to which they bear analogy, they are endowed with powers of motion, but ſtill more extenſively. They alſo ſerve, like the antennæ, as an eſſential character in the conſtruction of genera; and from their ſituation, the number of joints, termination, and relative proportion and ſize, are exceedingly uſeful for that purpoſe.

Theſe feelers, as their name implies, are conſidered as the organs of touch; and this is conceived probable, becauſe the inſect agitates theſe parts, and preſſes its food with them before it begins to eat. Some have ſuppoſed them to be the organs of hearing; and others of a ſenſe peculiar to inſects, which we are ignorant of. It has been aſcertained from experiment, that they are not abſolutely neceſſary to the life of the inſect, and that it even ſuſtains their loſs without much apparent inconvenience. Feelers are not common to all inſects. There are many whole genera deſtitute of them; as, for example, the fulgora, cicada, the ſeveral genera of the Linnæan cimices, nepa, notonecta, and various others.

Certain kinds of inſects are provided with feelers, both in the larva and perfect ſtate, as is particularly exemplified in the dytiſcus and hydrophilus genera, and again in the libellulæ; and it is worthy of remark, that theſe organs appear to be more immediately uſeful to the carnivorous tribes of inſects than to thoſe which feed on plants.

Olfactory organs.—Nature has denied the inſect race that particular part which is properly called the noſe; and it is further evident, that there is no organ within the head appropriated to the ſenſe of ſmell. From analogy, and compariſon with other animals, naturaliſts have been led to ſeek this organ in the head: and as inſects afford the moſt convincing evidence of being poſſeſſed of this faculty, ſome have placed it in the antennæ, and others in the feelers; neither of which, from attentive examination, appears calculated for this purpoſe.

It is ſufficiently clear that inſects poſſeſs the faculty of ſmell, if not in a very eminent degree, and that in many reſpects they are rather guided by this ſenſe than by the force of inſtinct. Inſects diſcover their food at a great diſtance, and, as it is ſuppoſed, by this means; and it is concluded likewiſe, that butterflies and moths are directed by the ſame ſenſe to the diſcovery of their mates. A female of phalæna quercus (eggar moth), incloſed in a box, and thus expoſed in an avenue of a wood, will attract the males in numbers to the ſame ſpot; and though ſhe cannot poſſibly be ſeen, they will appear fully ſenſible of her preſence. Admitting that theſe circumſtances may be otherwiſe accounted for, one argument at leaſt bears ſtrongly in its favour, namely, that of the fleſh fly (muſca vomitoria) being ſo far deceived by the ſimilarity of odour, as to lay its eggs on plants of the ſtapelia genus inſtead of animal ſubſtances. Theſe inſects, as the name implies, ſubſiſt in the larva ſtate on fleſh, preferring that which is putrid, or haſtening to the ſtage of putrefaction, and from whence, in conſequence, a powerful odour ariſes. The plants of the ſtapelia genus have the ſame ſmell; and the parent inſect, miſled by this means, actually depoſits her eggs on theſe plants.

As inſtinct never errs, though judgment may, it is a natural inference that the inſect is not in this inſtance under the controul of inſtinct, but of her own will, becauſe otherwiſe ſhe would not fail to lay thoſe eggs in fleſh, where the larva, when hatched, would be provided with food; while, on the contrary, the plants reſemble this food only in its offenſive odour, and thus, when hatched, the infant brood inevitably periſh. Does not this afford preſumptive evidence at leaſt, that the inſect is directed to theſe plants by the organs of ſmell?

If inſects then evince ſuch apparent proofs that they do poſſeſs this faculty, and that it appears likewiſe the ſeat of this faculty does not reſide in the head, it muſt be ſought after in ſome other part. The organs of ſmell, in all animals which reſpire air, is ſituated at the entrance of the organs of reſpiration: from this circumſtance it is conceived moſt likely that the reſpiratory ſpiracles on each ſide the body muſt be the true organs of that ſenſe. This idea was advanced by Baſter; yet it ſeemed to imply ſuch an inverſion in the ordinary courſe of nature, that it gained little credit. Of late years the ſame opinion has obtained the concurrence of the beſt anatomiſts. Cuvier is decidedly in favour of this concluſion, and, in addition to the reaſons hitherto ſtated in its ſupport, obſerves, that the internal membrane of the tracheæ appears well calculated to perform this office, being ſoft and moiſtened; and that the inſects in which the tracheæ enlarge, and form numerous or conſiderable veſicles, are thoſe which ſeem to poſſeſs the moſt perfect ſenſe of ſmell. Olivier endeavours to maintain that the palpi or feelers, and alſo the antennæ, are the olfactory organs in inſects.

Eyes.—Moſt inſects have two eyes. Theſe are placed in the anterior part of the head, and vary very much in their external figure in different tribes. Some of the Linnæan inſects of the apterous order have a greater number, the ſcorpions have eight, and the ſpiders from ſix to eight, and there are beſides other genera in which the eyes amount to more than two.

This pair of eyes in the inſect race is of a compound kind, while thoſe of the ſcorpion and ſpider are ſimple, and in this reſpect the difference is very remarkable. The compound eye is one of the moſt extraordinary deviations from the ordinary courſe of nature in the conformation of the organ of ſight; the ſimple eyes approach much nearer thoſe of other animals. By compound eyes we mean thoſe kinds which are reticulated, and when magnified are found divided into a great number of compartments, and of theſe every genuine inſect appears to poſſeſs two. Beſides theſe eyes, many of the neuropterous and hymenopterous families have three ſmall ſhining convex points placed in the middle of the head, and called by entomologiſts ſtemmata, the utility of which has never been aſcertained. The extreme minuteneſs of theſe organs does not allow the comparative anatomiſt the means of diſſecting them, but we ſtill think they can be no other than organs of ſight. Should this appear doubtful, becauſe we obſerve them in thoſe inſects, which are beſides furniſhed with a pair of eyes of the compound kind, it ſhould be recollected that ſcorpions and ſpiders, as before-mentioned, have ſeveral more eyes than a pair; and if, on the other hand, the ſimplicity of their ſtructure be conſidered as an argument againſt this concluſion, let it be obſerved that they poſſeſs every character in their form, appearance, ſituation, and immoveability, which the only kind of eyes theſe creatures are furniſhed with are known to poſſeſs. We, indeed, conceive it very probable, that thoſe three ſhining points, called ſtemmata, are truly organs of ſight; and that, conſequently, many inſects which appear to have only two eyes, have in reality no leſs than five.

The compound eye in inſects is ſo very different from that of other animals, that it would be difficult to perſuade ourſelves of its being an organ of ſight, had not experiments, purpoſely made, demonſtrated its uſe. If we cut out, or cover with an opake matter the eyes of a libellula, or dragon fly, it will ſtrike againſt walls in flight. The waſp is ſaid to aſcend perpendicularly in the air till it completely diſappears, when the compound eyes are treated in the ſame manner, and to remain perfectly immoveable when both the compound eyes and the ſtemmata are covered; in the firſt caſe it ſeems to follow the direction of its ſight upwards, in the other to be deprived entirely of the viſual organ, and uncertain whither to direct its flight.

The compound eyes are generally convex, and when viewed by the microſcope exhibit an innumerable multitude of hexagonal facets, ſlightly convex, and ſeparated from one another by ſmall furrows, which frequently contain fine hairs, more or leſs long. Theſe facets give, to the naked eye, the appearance of net-work, and amount to a greater or leſs number in different inſects. Leeuwenhoek counted 3181 in the eye of a beetle, and in that of the common houſe fly about 8000.

Theſe facets form altogether a hard elaſtic membrane, which, when freed from the ſubſtances that adhere behind, is very tranſparent. Each of theſe ſmall ſurfaces may be conſidered either as a cornea, or a cryſtalline, for it is externally convex, and concave internally, but thicker in the middle than at the edges, and it is alſo the only tranſparent part in this ſingular eye. Behind this tranſparent membrane is a ſubſtance, which varies greatly as to colour in different ſpecies, and which ſometimes forms, even in the ſame eye, ſpots or bands of different colours. Its conſiſtence is the ſame as that of the pigment of the choroides; it entirely covers the poſterior part of the tranſparent facets, without leaving any aperture for the paſſage of the light. Behind this pigment we find ſome very ſhort white filaments, in the form of hexagonal priſms, ſituated cloſe to each other, like the ſtones of a pavement, and preciſely equal in number to the facets of the cornea; each penetrates into the hollow part of one of theſe facets, and is only ſeparated from it by the pigment mentioned above. If theſe filaments are nervous, we may conſider each as the retina of the ſurface behind which it is placed; but it will always, in the opinion of Cuvier, remain to be explained how the light can act on this retina through a coat of opake pigment. This multitude of filaments, perpendicular to the cornea, have behind them a membrane, which ſerves them all as the baſe, and which is conſequently nearly parallel to the cornea: this membrane is very fine, and of a blackiſh colour, which is not cauſed by a pigment, but extends to its moſt intimate texture; we obſerve in it very fine whitiſh lines, which are tracheæ, and which produce ſtill finer branches that penetrate between the hexagonal filaments as far as the cornea: this membrane by analogy Cuvier calls the choroides. A thin expanſion of the optic nerve is applied to the poſterior part of the choroides. This is the real nervous membrane, perfectly ſimilar to the retina in red-blooded animals; it appears that the white filaments, which form the particular retinæ of the different ocular ſurfaces, are productions of this general retina, which perforates the membrane named choroides by a multitude of ſmall and almoſt imperceptible holes. To obtain a diſtinct view of all theſe parts, it is neceſſary to cut off the head of an inſect which has the eyes of large ſize, and diſſect it behind, each part will then be removed in an order, the reverſe of that above deſcribed.

The conſtruction of theſe compound eyes is admirably adapted to the convenience of the inſect, for as the eyes of inſects are immoveable, they would have loſt ſight of many objects, if their eyes had been framed like thoſe of other animals, but by theſe means they can eaſily view ſurrounding objects. It ſeems a falſe concluſion that as each of the facets which compoſe the compound eye is a diſtinct organ of ſight, any ſingle object muſt appear multiplied as often as there are facets; it is, on the contrary, far from improbable, that as objects do not appear double to our eyes, but that the viſual organ is ſtrengthened, and many illuſive appearances are corrected by the uſe of both, ſo the numerous inlets to ſight in an inſect may increaſe their field of view, and be productive of other advantages, of which we are ignorant.

Stemmata: the three ſmooth, gloſſy, hemiſpherical dots, ſituated at the vertex of the head, and which, as juſt obſerved in ſpeaking of the eyes, are ſuppoſed to be organs of ſight. Theſe are moſt conſpicuous in the hymenopterous order of inſects.

An experiment made by abbé Catalan tends to confirm the truth of this conjecture. With the view of obſerving whether an inſect could ſee equally well with both the eyes and ſtemmata, he covered the reticular eye of a fly with fluid pitch, leaving the ſtemmata open; he then put it under a glaſs, where it ran up and down without ſtriking againſt any object, and when he lifted the glaſs, it flew away towards the window. He took another fly, and covered with pitch the ſtemmata, leaving the reticular eyes open, and found that with theſe it ſaw equally well as before. Laſtly, he took a third fly, and covered both the reticular eyes and the ſtemmata, and this he found completely blind; it walked ſlowly under the glaſs, and when removed would not venture to fly. Act. Erudit. A.D. 1682.

Antennæ are thoſe delicate moveable horns which appear on the fore part of the head in all perfect and genuine inſects; and which, in many inſtances, are very remarkable for their beauty and elegance of ſtructure. The antennæ are extremely diverſified in form, and vary conſiderably in their proportional dimenſions in different tribes; and for this reaſon are conſidered by entomologiſts of material conſequence in diſtinguiſhing the various orders, genera, and ſpecies. Theſe parts are always articulated, or conſiſt at leaſt of more than one joint, including the baſe, and moſt commonly are compoſed of a far greater number; few leſs than eight, ten, or twelve, and ſome amounting to twenty, or even more. This articulated ſtructure of the antennæ is of infinite utility to the inſect, as it is thereby enabled to move theſe organs in every direction their wants or wiſhes may require.

Antennæ are not entirely peculiar to inſects; the cruſtaceous animals poſſeſs the ſame organs, though in other reſpects they differ ſo eſſentially, (ſee article CANCER,) as do likewiſe ſome of the apterous order of Linnæan inſects, which modern naturaliſts exclude from this claſs. Nor will it be amiſs to obſerve that, even according to Linnæus, many of his apterous inſects are deſtitute of antennæ, and are conſequently inadmiſſible on this account, upon his own definition, into the ſyſtem of entomology. Spiders and ſcorpions are of the latter deſcription. The organs termed antennæ are eaſily diſtinguiſhed from the tentaculæ of vermes, by having a ſhelly covering, and from the palpi or feelers of inſects, the latter being more numerous, and ſituated at the mouth. The Linnæan and Fabrician entomologiſts admitting the cancer, and other cruſtacea among the inſect tribes, allow four, or in ſome caſes even ſix antennæ to this race, but as we refer theſe to another claſs, we apprehend that the number of antennæ in all genuine inſects invariably amounts only to two. Thoſe inſects which have attained their laſt ſtate, and are therefore denominated perfect, and which poſſeſs ſix legs, are always provided with two antennæ. It is true that the larvæ of many inſects are not furniſhed with theſe organs, yet they are ſtill genuine inſects, becauſe in their complete ſtate they poſſeſs them; ſpiders and ſcorpions on the contrary, with all their organs complete, have no antennæ. A very conſiderable number of inſects, even in the larva ſtate, are not deficient in theſe organs, and in many, though not in all, there is no difference whatever between the antennæ of the larva and perfect inſect. The genera blatta, gryllus, mantis, phaſma, cimex, and various others of the hemiptera order, are furniſhed with antennæ, which exactly reſemble thoſe of the ſame ſpecies in their perfect ſtate.

No writer, who has attentively regarded the ſtructure of the antennæ in inſects, has hitherto pretended to determine preciſely the purpoſe for which nature has deſigned them, and thoſe who have not very maturely conſidered them cannot poſſibly be competent to decide ſuch a doubtful circumſtance. We know of nothing analogous to theſe organs in larger animals whoſe manners we might be ſuppoſed to have a better acquaintance with, and it is not therefore by analogy that this point can be determined. Some naturaliſts conceive that they are appropriated to a feeling more delicate than our own, and that they are ſenſible to the leaſt motion or diſturbance in the ambient fluid, or that they are the organs of ſome ſenſe unknown to us, and of which we cannot conſequently form the leaſt conception. Some ſuppoſe they ſerve to ſound, and occaſionally to probe the earth on which they move, or that they are the organs of hearing, of feeling, or ſmelling, and by the means of which they diſtinguiſh their proper food. Each of theſe conjectures is liable to objection, and can be conſidered as an opinion merely, while the real purpoſes of theſe organs may perhaps for ever remain unknown.

Though it is difficult even to conceive the immediate object for which the Creator has aſſigned theſe organs to the inſect race, we muſt reſt perſuaded that they are intended to anſwer ſome very important deſtination in the economy of the animal, as the medullary nerves, ariſing directly from the brain, may be traced into theſe parts, and followed throughout their whole extent. In ſome inſects alſo, which have the antennæ ſmall, the palpi are obſerved to be very large, as if they were intended to anſwer the ſame purpoſe, or partake of the ſame ſenſe, as the antennæ; and thus, by their mutual aid, ſupply the deficiency of antennæ. This will in ſome degree account, perhaps, for the manner in which nature ſeems occaſionally to counterbalance the want of antennæ in the larvæ of certain kinds of inſects which have palpi, but no antennæ; others in the ſame ſtate have antennæ and no palpi. Many that are deſtitute of both the two firſt-mentioned kinds are thoſe chiefly which prey on inſects, and the latter ſuch as feed on plants.

The antennæ, nevertheleſs, appear to us to be rather connected with the organ of hearing, than either that of feeling or ſmelling. The palpi, we have little doubt, are the organs of feeling, both from their texture, and the manner in which inſects are oftentimes obſerved to make uſe of them in touching their aliments; and the organs of ſmelling in inſects, however ſingular it may be imagined, we conceive to be no other than the apertures diſpoſed on each ſide the thorax and body. By the organs of hearing, we do not mean to conſider them as external ears, but as being in ſome manner auxiliary to the organ of hearing, the ſeat of which we ſuſpect to be contiguous to the baſe of the antennæ, the ſpot in which the ſame organ has been diſcovered in the cray-fiſh. They may anſwer this and ſome other purpoſe likewiſe.

We have previouſly obſerved, that nothing can be diſtinctly inferred of the actual utility of the antennæ from analogy; nor do the purpoſes to which inſects appear ſometimes to appropriate them aſſiſt our concluſions in a ſatisfactory manner. Many inſects, when they walk, fly, or take their food, have the antennæ directed forward; others, on the contrary, carry them inclining backward, like the cerambyces; ſome kinds lay them along their back; and others, as the elater tribe, diſpoſe them on each ſide the thorax. The ſpheges and the ichneumons bear their antennæ directly before them, and continually agitate them, whether in flight, when ſtanding, or ſeizing on their prey. In others, the antennæ have little perceptible motion. Some inſects are ſaid to cover their eyes with their antennæ when they ſleep; the diminutive ſize, compared with the magnitude of the eyes in moſt inſects, will not permit us to believe that this is the principal object of their deſtination.

Notwithſtanding the direct connection of the antennæ with the brain, inſects, it has been affirmed, can undergo their partial privation, or total loſs, without experiencing any ſenſible injury; and hence it has been concluded they cannot be neceſſary to the life of the inſect. If the fact be true, the latter inference muſt ſurely be admitted, but this will not diſprove their utility: nor will it diſcountenance the idea that the antennæ are requiſite for ſome important end. We well know, that in the animal economy of larger beings, not only the medullary nerves may be in part deſtroyed, but even the animal be deprived of a portion of the brain itſelf, without ſuſtaining mortal injury. The antennæ of inſects may not be abſolutely neceſſary to the life of the inſect, but are certainly ſo to its well being, and to the perfect exerciſe of all its functions.

The antennæ of the male inſects generally differ from thoſe of the females. It is principally the antennæ of the former that are plumoſe, or furniſhed with teeth, or tufts of feathers, while thoſe of the female appear like a delicate thread, entirely ſmooth, or only ſlightly pectinated. This is obſervable throughout the moth tribe. In coleopterous inſects the males are often diſtinguiſhed by the ſuperior ſize and beauty of the antennæ from the other ſex. The antennæ are characterized by entomologiſts according to their ſtructure under different names. Linnæus deſcribes the following: 1, Setaceæ, thoſe which gradually become taper towards the extremity; 2, Filiformes, ſuch as are of an equal thickneſs throughout; 3, Moniliformes, are filiform like the preceding, but conſiſt of a ſeries of round knobs, like a neck-lace of beads; 4, Clavatæ, ſuch as gradually increaſe in thickneſs from the baſe, and form a club at the end; 5, Capitatæ, like clavatæ, increaſe in thickneſs towards their extremity, but are diſtinguiſhed from thoſe by the form of their laſt articulation, which is larger and more rounded than the others; 6, Fiſſiles are like the laſt, but are divided longitudinally into three or four plates or laminæ; 7, Perfoliatæ are alſo capitatæ, but have the head divided horizontally, the plates being connected by a kind of thread paſſing through their centre; 8, Pectinatæ are thoſe which have lateral appendages, like the teeth of a comb, or plume of a feather, as in the moth tribe. 9. Ariſtatæ, ſuch as have a lateral hair, which is either naked, or furniſhed with leſſer hairs, as in the muſca genus. Each of theſe is alſo diſtinguiſhed according to their length, as breviores, thoſe which are ſhorter than the body; longiores, thoſe which are longer than the body; and mediocres, ſuch as are of the ſame length with the body, all which varieties are conſpicuous in the Linnæan tribe of cerambyces.

The ſtructure of the antennæ in inſects is of ſuch vaſt importance in the definition of genera, ſpecies, and ſexual diſtinctions, that it is to be regretted we have not a more comprehenſive number of terms by which their particular forms might be minutely diſcriminated. Linnæus affords us ſome, the utility of which is univerſally allowed; others which he propoſes require ſome reviſal and modification; and among the immenſe number of inſects diſcovered ſince the time of Linnæus, the antennæ of many exhibit characters which cannot be expreſſed by any of thoſe his work preſents. Fabricius has others, but theſe, even in addition to thoſe of Linnæus, are not adequate to the purpoſe.

Organs of hearing at the baſe of the Antennæ.

The organs deſtined by nature for the conveyance of ſounds to the ſeat of the ſenſes in the inſect race have never been clearly aſcertained. This can be attributed only, perhaps, to their minuteneſs, which defies inveſtigation, except in ſome few of the larger kinds, and theſe even phyſiologiſts ſeem never to have examined. In the cray-fiſh the organs of hearing are exemplified by Fabricius and Scarpa. Theſe were diſcovered within the head, at the baſe of the antennæ, through the hollow tube of which it is ſuppoſed the ſound muſt be conveyed. Perhaps, from the analogy in certain reſpects, which this tribe of cruſtaceous animals bears to inſects, it may be imagined that the organs of hearing in both are ſimilar: this is very probable; but theſe two orders of creatures differ ſo eſſentially in ſeveral particulars, that we wiſh to expreſs ſuch an opinion with caution.

In the cray-fiſh the labyrinth of theſe organs is very ſimple, reſembling a ſmall purſe, encloſed in a ſcaly cylinder open at both ends. The extremity by which this ſmall cylinder joins the baſe of the antennæ affords a paſſage for the nerves into the purſe. The oppoſite extremity is cloſed by an elaſtic membrane, which may be named tympanum, or, with more propriety, Cuvier thinks, feneſtra ovalis. The air, or water in which the animal lives, acts immediately on this membrane, the external part of which is obſervable at the lower ſurface of the baſe of the antennæ. That inſects are ſenſible of ſounds, and, conſequently, are furniſhed with organs of hearing, is demonſtrated by numberleſs obſervations.

Front: the anterior or fore part of the head, the ſpace between the eyes and the mouth.

Clypeus: ſhield of the head in coleopterous inſects, the part correſponding with the front of the head in the other orders. In the beetle kind it is advanced more or leſs upon, or over the mouth, and in ſome forms a ſort of cap, the rim of which extends ſo far over the head as to conceal the mouth beneath. The anterior edge of the clypeus is ſometimes miſtaken for the upper lip.

Vertex: the crown, or ſummit of the head.

Gula: that part which is oppoſed to the front of the head, uſually called the throat.

Trunk: the ſecond principal diviſion of which an inſect conſiſts, comprehending that portion which is ſituated between the head and the abdomen. The trunk includes the thorax, collar, ſternum, and ſcutel.

Thorax: a term indefinitely applied ſometimes to the whole trunk, the ſcutel excepted: in a ſtricter ſenſe it implies only the dorſal part of the trunk, and may be conſidered as expreſſive of that portion of the ſuperior ſurface which lies between the head and the baſe of the wings. Linnæus is not ſo explicit as could be wiſhed in his definition of the word thorax; according to this author, it is "the back part of the breaſt," and "upper part of the trunk between the head and ſcutel," yet it is evident, from the diſſimilar ſtructure in this part of the trunk in different inſects, that the definition requires rather more preciſion. It is not unuſual in the ſpecifical deſcriptions of inſects, both by Linnæus and Fabricius, to read of "thorax beneath," and "lower ſurface of the thorax," for the under ſurface of the trunk; though both endeavour to eſtabliſh it as a principle, that the word thorax applies to the back or upper ſurface of the trunk only. The appropriation of ſuitable terms, by which a thorax conſiſting of one, or of ſeveral pieces, may be diſcriminated from each other, is deſirable. In ſome the thorax is of a ſingle piece, as in the orders coleoptera and hemiptera; in that of lepidoptera it comprehends ſeveral ſegments, and a ſimilar ſtructure is ſtill more conſpicuous to view in the order hymenoptera. The firſt or anterior ſegment of the thorax in thoſe conſiſting of ſeveral pieces has been ſometimes called the collar; but in admitting this, we muſt by analogy define the coleopterous and hemipterous orders of inſects as having no thorax. This will be rendered plain, when we conſider that in the latter kinds of inſects the firſt pair of legs ariſes from what is uſually underſtood by the lower ſurface of the thorax; the interior ſegment in hymenopterous correſpond with the whole thorax in the former, for the firſt pair of legs ariſes from it exactly in the ſame manner. In the former the thorax of a ſingle piece is immediately ſucceeded behind by the ſcutel, while in the hymenoptera and lepidoptera a larger plane of one or more joints intervene between this true thorax and the ſcutel; and it is to this laſt mentioned dorſal ſpace that the term thorax is aſſigned. Hence it is evident that the language of entomology in this point is not altogether conſiſtent; becauſe what we denominate the collar in hymenoptera, is the thorax in coleoptera, and in coleoptera we find nothing analogous to the thorax of the other order, except the collar.

The thorax in thoſe inſects, which have that part conſiſting of a ſingle piece, or the firſt ſegment in ſuch as are of a compound nature, have the firſt pair of legs ariſing from the lower ſurface, and it is in this part that the muſcles that move the head, as well as this pair of legs, are ſaid to be contained. The thorax in different kinds of inſects varies conſiderably in form, and affords very excellent generical and ſpecifical diſtinctions. Some are armed with ſpines, others denticulated, marginated, &c.

Pectus.—The breaſt is the third ſegment of the body, or that to which the four poſterior feet are attached, and which is longitudinally divided at the anterior part by the ſternum. The wings in lepidopterous, and moſt other inſects, have their origin or baſe in the ſuperior part of the breaſt. The wings and elytra in the coleoptera and hemiptera deviate a little from this, as they are placed more immediately on the back, than in a lateral poſition; the breaſt contains the muſcles that move the wings, and give action to the four poſterior legs. This part is capable of being compreſſed and dilated, the alternate motion of which is very evident in ſome inſects of the butterfly or moth kind, when held between the fingers. The power of compreſſion and dilatation is ſuppoſed to ariſe from the action of ſome very ſtrong muſcles, which ſeem to approximate the dorſal and ventral ſurfaces. They are four in number on each ſide, and differ very much in colour and texture from the other muſcles, being reddiſh yellow, and extremely looſe. It has been conjectured theſe muſcles may aſſiſt the motions of the organs of flight.

Sternum, or breaſt bone.—By this term entomologiſts define that portion of the middle part of the breaſt which is ſituated between the baſe of the four poſterior legs. This piece terminates inſects anteriorly in a ſomewhat acute point, in others it appears rather bilobate, and in the far greater ends obtuſely or in an obtuſe lobe. There are few inſects in which the ſternum is remarkable, either from its magnitude or figure. In ſome of the coleopterous tribes, as hydrophilus and dytiſcus, this part is moſt conſpicuous.

Scutel, or eſcutcheon (ſcutellum, Linn.) the lobe-like proceſs, ſituated immediately at the poſterior part of the thorax, in ſcutellate inſects. The ſcutel is not of the ſame form in all inſects, yet its general tendency is towards a ſub-triangular figure. In the coleopterous tribes it approaches neareſt to this form; its deviations incline more or leſs to heart-ſhaped, with the tip pointing backwards. The ſame figure prevails in ſome of the hemiptera order. In the neuroptera, hymenoptera, and diptera, the triangular contour is ſtill obſervable under various modifications, and moſt commonly with the poſterior tip rounded off. Sometimes, as in ſeveral of the hymenopterous inſects, the poſterior end is armed with ſpines, or denticulations; this is, however, not uſual, the ſcutel in the far greater number of inſects, whether terminating in a point, or rounded, is commonly unarmed. In point of ſize the ſcutel is more variable than in figure; in ſome it is ſo ſmall as almoſt to eſcape notice, merely forming a point at the extremity of the thorax, as we obſerve in certain kinds of the beetle tribe; in others it is very conſpicuous; ſometimes it is ſo large as to cover the middle of the back, and in others, as the ſcutellate kinds of cimices, and a few of the genus acrydium, it expands over the back, entirely concealing the wings and wing-caſes, and covering the margin of the abdomen.

Abdomen is the laſt principal diviſion, or poſterior part of the body, and is connected with the breaſt, either cloſely, or at a diſtance, by means of a fillet. The abdomen is compoſed of annular joints or ſegments, the number of which vary in different inſects. Each of theſe rings is pierced at the ſide with a ſingle pore, which in ſome kinds are of conſpicuous ſize, in others ſcarcely perceptible, and theſe are the orifices of the ſpiracles through which the inſects breathe. The upper part of the abdomen is called by entomologiſts tergum; the inferior, or belly, venter. The opening at the poſterior part of the abdomen is the vent, and the extremity in moſt inſects contains the organs of generation: there are exceptions to the latter.

The total movement of the abdomen is not very obvious, except in inſects which have that portion of the body pediculated, as in many of the hymenopterous genera. It has then a real joint, in which the firſt annulation is indented above, and receives a projecting proceſs from the breaſt on which it moves. This joint is rendered ſecure by elaſtic ligaments, which have a conſiderable degree of force. Some muſcles which ariſe within the breaſt are inſerted into the firſt ring, and determine the extent of its motions. The partial motion of the rings is produced by very ſimple muſcles, conſiſting of fibres which extend from the anterior edge of one ring to the poſterior edge of that which immediately precedes it. When the dorſal fibres contract, the ſuperior part of the abdomen being ſhortened, it turns up towards the back, but when the contraction takes place in the ventral or lateral fibres, the abdomen is inflected towards the belly, or directed towards one of the ſides. The extent of the motion, however, depends upon the number of the rings, and their mode of junction. In the coleoptera, for example, the rings only touch each other by their edges, and the motion is very limited, but in the hymenoptera they are ſo many ſmall hoops, which are incaſed one into another like the tubes of a teleſcope, ſo that ſcarcely half, and ſometimes not above one-third, of their extent appears viſible externally.

The form, connection, proportions, and appearance of the ſurface of the annulations of the abdomen, afford numberleſs ſpecifical diſtinctions; and ſo likewiſe do the appendices at the extremity of the abdomen.

The abdomen contains the inteſtines, the ovary, and part of the organs of reſpiration: it is affixed to the thorax, and in moſt inſects diſtinct from it, forming the poſterior part of the body. The abdomen is compoſed of rings or joints, by which means the inſect can lengthen or ſhorten it, or even move it in different directions. The upper part of the abdomen is called tergum, the under part venter, the vent is in the poſterior part.

Tail.—An appendage of any kind terminating the abdomen is uſually denominated the tail. Theſe appendages vary in figure conſiderably in different inſects, and many tribes are totally deſtitute of them. They are ſuppoſed to be deſtined to direct the motion of the inſect in flight, to ſerve for its defence, and for the depoſition of its eggs. In ſome inſects this tail is ſimple, (ſimplex,) and yet capable of being extended and withdrawn at pleaſure. In others elongated (elongata). Some are ſetaceous (ſetacea) or briſtle-ſhaped, as in the raphidia. Thoſe termed triſeta have three briſtle-ſhaped appendices, as in the ephemera. In ſome it is forked (furcata), as in podura. When it terminates in a pair of forceps it is called forcipata. In the blatta and others it is folioſa, or reſembling a leaf. In the panorpa it is furniſhed with a ſting, and is called teliſera; this laſt may be more properly referred to the next.

Aculeus, ſting, an inſtrument with which inſects wound and inſtil a poiſon. The ſting generally proceeds from the under part of the laſt ring of the belly: in ſome it is ſharp and pointed, in others ſerrated or barbed. It is uſed by many inſects both as an offenſive and defenſive weapon: by others it is uſed only to pierce wood, or the bodies of animals, in order to depoſit their eggs. In waſps and bees the ſting is known to be retractile: in the ſcorpion fixed or immoveably connected to the laſt ſegment of the body. In ſome inſects it is the male only, and in others the female only, which nature has provided with this inſtrument: it is not frequently met with in both ſexes of the ſame ſpecies; and the far greater number of inſects have no ſuch organ.

Spiracles.—Theſe are the apparent orifices to the organs of reſpiration in inſects, and which are known to many entomologiſts by the name of ſtigmates. The ſpiracles are a ſeries of ſmall apertures diſpoſed along both ſides of the abdomen: ſome few appear on each ſide the thorax, the remainder on the abdominal rings, every one of which is pierced on each ſide with a ſingle aperture. Among the ancients it was generally believed that inſects had not the power of breathing, and this they concluded becauſe they have no reſpiratory organs, as in larger animals. The moderns are better informed; from the effects produced on inſects by the pneumatic machine it is demonſtrated, beyond diſpute, that they do reſpire, though not in the manner of other animals. An inſect placed in the receiver of this machine, upon the air being exhauſted, becomes ſuffocated, and dies in a very ſhort time; and the ſame reſult will be produced by cloſing the apertures of the ſpiracles with wax, oil, or other glutinous ſubjects, in a ſufficient degree to preclude the paſſages of air through theſe openings, a fact which in itſelf may be regarded as concluſive, that theſe are the true organs of reſpiration in inſects. They are alſo conſidered, and with much probability, as the organs of ſmell, as will be ſhewn hereafter.

Reſpiration being one of the moſt important actions in the life of every animal, it can be no matter of aſtoniſhment that great pains have been taken by naturaliſts to inveſtigate the organs of breathing in inſects; numberleſs facts contributed to prove its exiſtence, but this being accompliſhed by means unknown in the other tribes of animals, it became an object of the greater ſolicitude to explain the manner in which it was effected. Malpighi, Swammerdam, Reaumur, and Lyonet, are among the number of the earlieſt writers on this ſubject, and from their obſervations it appears, that in the caterpillar there are two air-veſſels, called tracheæ, which extend throughout the whole length of the inſect; from theſe proceed an infinite number of ramifications, which are diſperſed in various directions through the body; but the principal are thoſe which form a direct communication between the tracheal veſſels and the openings in the ſides of the body. Of theſe there are nine on each ſide placed nearly at equal diſtances, one extremity terminates in the orifice of the ſpiracle, and the other enters the principal tracheal veſſel diſpoſed neareſt, or on that ſide of the body. Theſe lateral or ſpiracular veſſels ſeem calculated for the reception of air; they are of a cartilaginous nature, and when cut preſerve their figure; they are conſtantly obſerved in a temperate ſtate of moiſture, and communicate in many inſects in the form of conſiderable veſicles, at their junction with the principal tracheæ.

Some writers have imagined, that though the air entered by the ſpiracles into the trachea, it did not come out by the ſame orifice, but was expired through a number of ſmall holes in the ſkin of the caterpillar, after being conveyed to them through the extremities of the finer ramifications of the tracheal veſſels. Others ſuppoſed, that the inſpiration and expiration of air through the ſpiracula, and that there was no expiration of air through the pores of the ſkin. Experiments were made to aſcertain the truth of theſe opinions, by plunging the caterpillars into water, or anointing them with fat and greaſy ſubſtances, either partially or entirely. The number of ſmall bubbles which are obſerved to cover the ſurface of their bodies when they are immerſed in water, is ſaid not to ariſe from the air included in them, and then proceeding from them, but to be formed by the air which is lodged near the ſurface of their bodies, in the ſame manner that it is about all other ſubſtances. To render the experiment more accurate, and prevent the air from adhering to the ſkin, before the caterpillars were plunged into water, they were bruſhed all over with a hair pencil, and after this, it is affirmed, that few air bubbles were found on their bodies when immerſed in water. The latter experiments were made chiefly by Bonnet, in order to aſcertain the truth of ſome opinions previouſly advanced by Reaumur.

A caterpillar, according to Bonnet, may be retained a conſiderable time under water, without deſtroying the principle of life, and will recover ſoon after being taken out of the water, when it has lain till all apparent ſigns of life have ceaſed. A caterpillar partially immerſed in water, or with two or three of the ſpiracles remaining in the open air, does not become torpid for a conſiderable time. One caterpillar lived eight days ſuſpended in water, with only two of its anterior ſpiracles in the air. During this time it was obſerved, that when the inſect moved itſelf, little ſtreams of bubbles iſſued from the ſpiracles on the left ſide; from this and other experiments, however, it appeared, that the anterior pair of ſpiracles, together with the poſterior pair, are of the greateſt uſe in reſpiration.

It has been remarked, that "when we conſider the great ſolidity of the caſes or cones of certain kinds of inſects, it is not eaſy to conceive how they can live ſeveral months under the earth in ſpaces ſo confined, and almoſt impervious to the air. If reſpiration was abſolutely neceſſary to their exiſtence, and indeed if they did reſpire, the ſame ſituation ſeems to preclude a continuance of the operation, as the air would ſoon be corrupted, and unfit for the offices of life."

But though it is difficult to aſcertain the reſpiration of ſome inſects at certain periods of exiſtence, except from its effects in preſerving life, which from analogy and collateral circumſtances we are aſſured muſt depend on this cauſe, there are others to whom reſpiration ſeems neceſſary in a very extraordinary degree. Many inſtances of this might be adduced; but in no tribe is this more clearly ſhewn than in thoſe of the aquatic kinds. There are a number of the latter which are obliged to keep their tails ſuſpended on the ſurface of the water for this reaſon, and in proof of which, if they be plunged entirely under water, they become agitated and uneaſy, firſt endeavouring to eſcape and riſe again to the air, or, if prevented, ſhortly fall to the bottom and die. Some aquatic beetles reſiſt the trial for a conſiderable time, while their larvæ can ſupport the privation of air only for a few minutes. A remarkable evidence of the ſame kind occurs in the larvæ of muſca pendula, which, though they live in the mud at the bottom of the water, have the power of extending the tube of the tail to a great length, in order to elevate it to the ſurface of the water; and the extremity of it is furniſhed with a tuft of fine hairs, which preſerves that part buoyant on the ſurface, while the creature remains in a ſtate of quieſcence. A ſimilar verticillated organ is placed at the tip of the tail in the larva of muſca chameleon, which alſo lives in the water; this is expanſile or retractile at the pleaſure of the inſect; when at reſt the expanded tail reſts upon the ſurface of the water, the remainder of the body being ſuſpended in that element with the head downwards, and when it is inclined to deſcend, it has only to retract or cloſe up the rays of the tail to effect its purpoſe; an expanſion of the tail will again raiſe the larva to the ſurface.

Upon anatomical examination, it has been found that the body of this laſt mentioned larva contains two large tracheal veſſels: theſe air-veſſels extend from the head to the tail, terminate in the reſpiring tubes, and receive the air from them. The larva quits the water when the time of its transformation approaches, and enters into the earth, where the ſkin hardens and forms a caſe, in which the pupa is formed: ſoon after the change, four tubes or horns are ſeen projecting from the caſe, which ſome ſuppoſe to be the organ for communicating air to the interior parts of the inſect: they are connected with little veſicles which are filled with air, and by which it is conveyed to the ſpiracles of the pupa. The larvæ of gnats, and various other little aquatic inſects of the ſame kind, are furniſhed with ſmall tubes that play on the ſurface of the water, and convey the air from thence into the body of the inſect.

Nothing can be more evident than that inſects do not reſpire by the mouth, like other animals. To determine the reſpiratory organs in inſects, and alſo to aſcertain in what manner this function of life is performed, has been an object of ſolicitude with many. The experiments made with this view are numerous and concluſive, the reſult demonſtrating, beyond diſpute, that the ſpiracles are the apertures through which the air is drawn into the body. This may be inferred from the writings of Swammerdam, Malpighi, Reaumur, Muſchenbröek, Degeer, and many others, who treat at large on this particular ſubject.

Theſe ſpiracles exiſt in every ſtage of life, in the larva and pupa as well as perfect ſtate. They are viſible externally as a ſmall knob of a roundiſh or oval form, ſlightly elevated and perforated in the middle: the aperture is uſually oblong or ſubovate, and is the orifice of the channel which communicates with the trachea, one of which is diſpoſed lengthwiſe on each ſide of the body.

The extreme tenacity with which many inſects retain life, while deprived of air, ſeems to indicate that they exiſt much longer without the benefit of this renovating fluid than moſt other animals; and that in certain caſes they may endure a temporary ſuſpenſion of the functions of reſpiration. But nevertheleſs every experiment tends to confirm the fact, that ſo far as reſpiration is neceſſary, it is performed only by means of theſe ſpiracles, the cloſing of which, to the total ſecluſion of the air, will at length deſtroy the vital principle.

Lyonet has obſerved, that although it is a general rule that every thing which lives reſpires, it is not perhaps without exceptions in inſects. Many give reaſon to doubt of their reſpiration, at leaſt in certain ſtages of their exiſtence. "I took, for inſtance," ſays he, "ſome of thoſe large cantharides of the willow, whoſe ſtrong ſmell, though not very diſagreeable, is felt at a conſiderable diſtance. I put them under a glaſs, where for a long time ſulphur had been burning on a piece of copper made red-hot, that the ſulphur might continue to burn in the midſt of its own vapours; and although there aroſe ſo thick a ſmoke that it almoſt hid the inſects from ſight, they ſupported theſe vapours for more than half an hour, without ſuffering, that I could perceive, the ſmalleſt injury." Inſects, we are aware, may live ſome time confined in this manner amidſt the vapours of burning ſulphur, but the inſtance adduced by Lyonet is ſtill remarkable, for we have known the ſame experiment tried with theſe cantharides, in the reſult of which the inſects died within the ſpace of time mentioned by Lyonet; and if, inſtead of ſulphur, we employ camphor, the reſpiratory powers ceaſe, and life becomes extinguiſhed in a ſhorter period.

This author argues, that from the ſolidity of the greater number of the cones made by the pſeudo-caterpillars, and moſt of the ichneumon flies, it cannot be conceived poſſible how theſe inſects ſhould live ſeveral months under ground, in a place ſo cloſe and impenetrable to the air, if they were to breathe in it. "Neither," ſays he, "would I maintain the reſpiration of chryſalids; at leaſt one experiment convinces me there are ſome which do not breathe. I took the chryſalis of the ſphinx liguſtri, which being one of the largeſt is the moſt proper for experiments. It had, beſides, the two anterior ſpiracles ſo open, that with a common magnifier I could ſee into the ſubſtance of its body, and obſerve a ſmall vacuum between it and the cover. This made me hope, that if reſpiration took place in the chryſalis this would give me certain proofs of it. Two or three months before the perfect inſect iſſued from its cover I dug it up, and covered ſeveral times, firſt one and then two, and afterwards ſucceſſively, the whole of its ſpiracles with ſoap water. At each time I obſerved, for a conſiderable ſpace, with the glaſs, the ſpiracles thus covered, to ſee if any bubbles of air were formed above, which would naturally have happened, had theſe ſpiracles ſerved as conduits to the air in reſpiration; but with all my attention I could perceive none. Some days afterwards I repeated the ſame experiment, in a manner to me ſtill more deciſive. Inſtead of covering the ſpiracles with ſoap-water, I covered each with a little bubble of air, taken from the froth of the ſame water, that the air might enter and go out more freely. But my curioſity was not more gratified: theſe bubbles, which ought to have riſen or ſunk at each expiration or inſpiration of the chryſalis, preſerved conſtantly the ſame appearance, till their pellicle becoming dry, they burſt. When the perfect inſect had iſſued from this chryſalis, I took it up inſtantly, waſhed the inſide of it, and obſerved at the ſpiracles little bundles, compoſed of a great number of very white threads, of which the longeſt were about two lines in length. Theſe appeared to me the exuvia of the pulmonary organs. I blowed on each of the ſpiracles with all my force, by means of a very ſlender tube, but my efforts could neither ſwell nor move any of thoſe fragments of the veſſels which were attached to them internally; but this muſt neceſſarily have happened, had the communication of the external air by theſe ſpiracles in the bronchiæ remained open, or had the inſect, when incloſed in its chryſalis, been able to breathe through them. It may be inferred from this, that the chryſalis of ſphinx liguſtri lives for ſome time without reſpiration, and that its two anterior ſpiracles ſerve only to facilitate the evaporation of the ſuperabundant humours, and to permit the external air to ſupply their place." Lyonet, however, admits, that it is not on the ſingle experiment here related that the knowledge of the reſpiration in inſects is founded; and that this experiment does not appear deciſive. We have unequivocal proofs of the reſpiration of inſects; a fact demonſtrated beyond all doubt in numbers of the aquatic kind, and as to lungs, he ſays, we may aſſure ourſelves that inſects poſſeſs them without being at the trouble of diſſection. The ſpiracles are called ſtigmata by the modern naturaliſts; ſtigmates of the French.

Members.

Legs.—In all inſects that are furniſhed with wings the pedes or legs amount to ſix, and never exceed that number; and the ſame is obſervable of the true feet in the larvæ of thoſe inſects; the latter have ſpurious feet to a greater amount, but the true feet do not exceed ſix. The apterous tribe in this, as in other particulars, afford exceptions: thoſe of the pediculus, pulex, lepiſma, podura, and acarus genera have only ſix legs, and theſe are attached to the body in the ſame manner as in winged inſects: the ſcorpio, aranea, and phalangium genera have eight; the cancer, if admitted, have as many; and in the oniſcus, julus, and ſcolopendra, they are far more numerous, varying from ten or twelve to twenty, fifty, or even thrice that number.

The leg of an inſect may be divided into four, or, more correctly, into five parts; coxa, the firſt joint, or haunch, at the baſe; femur, the thigh; tibia, the ſhank; tarſus, the foot; and unguis, the claw. Each of theſe parts is enveloped in a hard caſe of a horny ſubſtance, and varies in ſhape in different inſects; the form of the feet in all the kinds being admirably adapted to their mode of life, and convenience of their motion. Some of theſe are diſtinguiſhed by particular terms, as, curſorii, thoſe formed for running (and which are the moſt numerous); ſaltatorii, thoſe conſtructed for leaping; natatorii, thoſe employed in ſwimming, &c. From the different conformations of theſe limbs, it is eaſy to recognize, even in the dead inſect, the mode of life which the ſpecies is deſtined by nature to purſue. Thoſe which have the legs adapted for running or walking have them long and cylindrical: the thighs of the leapers are remarkably large and thick, with the ſhank long and commonly arched, by which means they poſſeſs great ſtrength and power for leaping: the legs are broad, ſerrated, and ſharp at the edge, in thoſe accuſtomed to dig in the earth; and ſuch as are of the aquatic kind have the legs, eſpecially the poſterior pair, long, flat, and ciliated, or fringed at the edge with hair. The leapers are well exemplified in the ſaltatorial kinds of curculio; and the ſwimmers in the genera hydrophilus and dytiſcus.

The coxa, or ſmall joint at the baſe, connects the leg to the body, and moves in a correſponding cavity of the collar or thorax in the firſt pair, or breaſt in the two poſterior ones. This part varies in form: in the cerambyx coccinella, and other tribes in which the feet ſerve for walking only, its ſhape is globular: ſuch as require that the feet ſhould have a lateral motion, and which is neceſſary to thoſe that dig into the earth, have the coxa broad and flat; this is alſo obſervable in ſome of the aquatic beetles; in the dytiſcus, the coxa of the poſterior legs is conſolidated with the trunk, and immoveable; and in the blatta, lepiſma, and others which walk very rapidly, it is compreſſed into a lamellate form.

There is more diverſity in the form of the thigh than the coxa to which it is united. The articulation of theſe two parts is internal, and is produced in ſuch a manner, that when the animal is in a ſtate of repoſe, it is parallel to the inferior ſurface of the body. It is limited to a forward and backward motion, with reſpect to the firſt piece. The nature and extent of the motions of the thigh appear to determine its form. In thoſe inſects which walk much and fly little, as the carabus, cicindela, &c., the thigh has two little prominences at the baſe, which appear to be intended for removing the muſcles from the axis of the articulation. Thoſe which require ſtrong muſcles adapted to leaping have the thigh not only thick but greatly elongated, as in the gryllus and locuſta tribes, the pulices, or fleas, &c. And in the ſcarabæi, ſcarites, and other coleoptera, and alſo in the mole cricket (acheta gryllotalpa), all which burrow in the earth, the thigh is moved with much force, and has an articulated ſurface correſponding to the flat part of the coxa on which it reſts. This part is ſometimes ſpinous.

Tibia, or ſhank, is the third joint of the legs, and moves in an angle, according to the direction of the thighs. The figure of this part depends eſſentially on the uſes to which the habits of the inſect require it to be applied; in the natatorial kinds it is uſually flat and ciliated, at leaſt the tibia of the poſterior pair, and in many others, as in a variety of the burrowing kinds of beetles, it is ſerrated. In the mantis genus, to which ſhanks of the anterior pair of legs ſerve as weapons of defence, they are broad, flat, and acute at the edge, and theſe they wield with dexterity in the manner of a ſabre. The ſhank is more frequently ſerrated or ſpinous than the thighs.

The tarſus, or foot, is the fourth joint, or laſt portion of the leg, except the claw. This part conſiſts in general of five joints: this is uſually the number in the coleoptera, hymenoptera, and diptera; in ſome of theſe, however, and alſo in the hemiptera, there are only four articulations in this part of the leg, as we obſerve in cerambyx, gryllus, and others; in libellula, forficula, &c. three: in the anterior feet of mantis and nepa only one; and in thoſe of the nymphales family of butterflies none. The figure of the tarſus is more variable than any other portion of the leg, and is in a moſt ſingular manner adapted to the inſect's mode of life. The articulations in ſuch as walk on the ſurface of the earth are ſlender, thoſe which burrow in the earth have them more robuſt. Many of thoſe which inhabit waters have them flat and ciliated at the edges, as in the hydrophilus. Others are furniſhed with briſtly tufts, or vaſcular fleſhy tubercles, which enable them to move with ſecurity on ſmooth and ſlippery bodies in any direction; an admirable example of this preſents itſelf in the common houſe fly, which "treads the ceiling, an inverted floor," with the ſame facility that other inſects walk on the ſurface of the ground. An occaſional difference in the number and form of the joints of the tarſus is ſometimes obſerved in the two ſexes of the ſame ſpecies. The motion of each joint of the tarſus is performed in a ſingle plane, and is directed by two muſcles in each joint, one of which is ſmall, and placed on the dorſal ſurface, the other larger, and ſituated beneath.

Unguis, or claw, the termination of the tarſus; in the greater number of inſects there are two claws attached to each tarſus: ſome have only one, and in others furniſhed with two, there is an intermediate proceſs forming by this means three. An appearance ſimilar to this is ſeen in the legs of the lucanus, but this, on minute examination, is found to be a diſtinct joint alſo, armed with a pair of claws, preciſely reſembling thoſe which, more obviouſly from their ſize, appear to terminate the tarſi. It is conſiderably ſmaller, but as perfectly well defined.

Reaumur, Weiſs, Borelli, and Cuvier, have publiſhed ſome curious remarks on the laws of motion obſerved in the legs of inſects, ſome of which are very intereſting. The relative proportion of the feet ſeems to determine, in a certain degree, the particular manner in which each inſect moves either in walking or leaping. When, for example, the legs are all equal, the movement is uniform, but when ſhort it is ſlow, and when long, it moves with rapidity. Thoſe inſects, therefore, which have the legs long, as in the phalangium, and ſome others, run very quickly: and, on the contrary, the acarus, pediculus, and thoſe others, which have the legs ſhort, are remarkable for the ſlowneſs of their pace. When the anterior feet are longeſt, as in certain cerambyces, their ſpeed is retarded when moving on even ground, though, in climbing, this length of the anterior legs is an advantage. When the poſterior feet are longeſt, they uſually afford the inſect the ability of leaping, as in the locuſt, acheta, and other families; but ſuch a ſtructure impedes its ſpeed in walking; and does not always enable it to leap; the inſects of the leucopſis and chalcis genus, though their poſterior thighs are very large and thick, are ſuppoſed to be incapable of this action. The latter inability is attributed to the great curvature of the legs, thoſe inſects which are truly of the ſaltatorial kind, as in the gryllus genus, being remarkably ſtraight.

Alæ, or *wings*.—Wings, the organs appropriated to flight. Theſe in different inſects vary from two to four, and are attached to the lateral part of the breaſt, cloſe to the lower margin of the thorax. They are placed to an equal amount, and in a correſponding ſituation on both ſides of the inſect, whether the number be two or four. Thoſe inſects which are furniſhed with only one pair of wings, have both of an uniform appearance and ſize. Such as have two pair moſt frequently differ, the firſt being larger than thoſe behind: there is alſo a difference in ſhape, and very commonly a conſiderable variation in the ſpots, markings, and other particulars, notwithſtanding the prevailing hues in all the wings may be the ſame. In general, the poſterior pair is paler, and the marks obſcure.

The wing properly ſo denominated ſhould be diſtinguiſhed from the elytra or wing-caſes, thoſe hard ſhelly coverings of the true wings in the alated kinds of coleoptera. Theſe wing-caſes, or ſheaths, are often confounded with the wings; but they are really not wings from their ſtructure or ſubſtance, nor do they anſwer the purpoſe of flight: they merely open to afford the true wing, concealed beneath, the power of expanſion and motion, and cloſe down upon the wing, when the inſect is at reſt, to preſerve it from injury. Of this we have ſpoken more largely in deſcribing the elytra. The ſemi-cruſtaceous wings of the hemipterous orders partake of an intermediate character between the wing-caſes and wings, as already noticed in its proper ſection. The wings and elytra in ſome inſects, and the wings and hemelytrous wings in others, are ſo intimately connected, that we conceived it requiſite, in order to avoid miſconception, to advert again to this circumſtance.

A ſkeleton of nerves, more or leſs numerous, and differing exceedingly in diſpoſition, placed between two thin and cloſely united membranes, conſtitute the true wing in inſects. This conformation is very clearly exemplified in that deſcription of wings which is uſually termed tranſparent, as in the common houſe-fly and the bee. The true wing, by means of which the inſect is enabled to fly, is always conſtructed in this manner, whatever may be its appearance externally, ariſing from a ſuperficial covering of down, feathers, hair, or any other cauſe. The variety in the form and ſtructure of the wings, in the number, figure, and diſpoſition of the nerves, or the colours with which they are adorned, is infinite. The diverſity in the diſpoſition of the nerves is evident from a compariſon of the ſimply conſtructed wing of the common houſe-fly (muſca domeſtica) with the complex wing of the panorpa, or the ephemera, or the wing of the forficula (earwig), which conſiſts of a ſeries of ſingle nerves, with the elaborately wrought lattice-work of the wing of the libellula. The whole of the lepidoptera tribe exhibit the ſuperficial coating of feathers, down, or hairs; and upon the removal of theſe, the wings are found conſtructed exactly in the ſame manner as the tranſparent wings of the other tribes. A variation in the form of the wing, as well as its texture, is manifeſt throughout all the inſect tribes of the winged kind. Thoſe of the coleoptera have two membranous wings, which fold upon each other, forming a plait, or double at their external margin; which fold is accommodated by a peculiar joint in the main rib of the wing, and the peculiar diſpoſition of the nerves in the middle of the wing contiguous. In the hemiptera the wings generally fold longitudinally, without any tranſverſe double, ſo that in expanſion theſe parts open ſomewhat like a fan: the forficula is an exception in this order, the wing in this genus being doubled acroſs as in the coleoptera. The wings of the lepidoptera are neither doubled acroſs nor folded longitudinally; they are entirely flat, and incapable of contraction and dilatation. In the papilio genus they are endowed with the power of erection, which is not the caſe in the phalæna genus, though occaſionally obſerved among the ſphinges; the phalænæ have the lower wings concealed under the anterior pair, the latter being laid in a flat poſition over them. The wings of the lepidoptera are downy, and often decorated with very beautiful colours diſpoſed in the moſt pleaſing and varied manner. The neuroptera in general have the wings flat; this is not invariable: they are conſtantly membranaceous, and reticulated with nerves. In the hymenoptera the wings are membranaceous, generally flat, but ſometimes folded, when the inſect ſettles, as in the waſp genus. The dipterous order cannot be confounded with the preceding, as they have only two wings, without any wing-caſes: they are membranaceous as in the former.

Inſects of the dipterous family, bees, and various kinds of hymenoptera, and many others, poſſeſs the powers of flying in a more perfect degree than any claſs of animals beſides; ſurpaſſing in this reſpect even the bird tribe. All inſects that are furniſhed with wings have not an equal celerity of motion in the air; the movements of the wings in ſome inſects is more circumſcribed than in others. The muſcles that move the wings are not yet very well aſcertained: they are ſaid to be ſituated in the breaſt, and to be of two kinds; the firſt of theſe are ſmall and ſhort, and are intended to extend or fold the wings, at the ſame time that they move them to and fro from the body; the others, which are ſomewhat longer, are calculated to produce theſe motions of elevation and depreſſion which the wings perform, very ſtriking examples of which are found in the two genera papilio and libellula. The wing-caſes of the coleoptera are not moved, it appears, by the pectoral muſcles like the wings.

The dipterous inſects, when flying, emit a loud buzzing ſound, occaſioned, as it is believed, by the wings and balancers ſtriking againſt each other. The noiſe of the cricket and locuſt is produced by the friction of the wings, or baſe of the wing-caſes againſt the poſterior edge of the thorax; and which is obſerved likewiſe to be the caſe with the cerambyx, leptura, and various other inſects.

In all inſects of the winged kind theſe organs preſent the greateſt diverſity, and afford characters both of genera and ſpecies leſs liable to fluctuation than common obſervers would conceive. The number, figure, conſtruction, proportion, conſiſtence, and texture of the wings have enabled naturaliſts to diſtribute inſects into principal families with conſiderable preciſion; and their minor peculiarities of ſpots, marks, and colours, have furniſhed ſubordinate characters of the utmoſt utility in defining ſpecies. Linnæus derived much aſſiſtance from an attention to theſe parts; later writers have in many inſtances regarded them more cloſely; and in the further progreſs of the ſcience, we are perſuaded theſe parts may be conſulted with much greater advantage ſtill.

There are many terms at preſent in uſe, intended to deſcribe the different kinds of wings, the principal of which ſhould be underſtood by the ſtudent in entomology.

The wing in all inſects is diſtinguiſhed, with reſpect to its ſurfaces, into ſuperior and inferior; that above is denominated the ſuperior, and that beneath the inferior. In the deſcription of wings, the terms anterior, poſterior, interior, and exterior parts, and ſometimes the diſk, occur very frequently. The anterior part or margin is that next the head; the poſterior, that towards the vent; its exterior, that towards the outer edge; and the interior, that next the abdomen: the diſk is the centre of the wing. Theſe terms are not always applied with preciſion by entomologiſts: the baſe of the wing, next the point of connection to the breaſt, is ſometimes called the anterior part; and in this caſe, every other part varies its name in a relative proportion: and this appears to be a correct method of deſcribing the parts of a wing in its natural ſtate, while the inſect is at reſt, with the wings down; but it applies only to thoſe which diſpoſe their wings longitudinally: it would be altogether inapplicable in deſcribing a papilio, in which the wings are expanded and ſtretched forward; or in the libellula, which reſts with the wings in the ſame poſition. The anterior margin of a wing is, therefore, generally underſtood as implying the coſtal edge, and which is ſo named becauſe it is formed by the main rib that extends from the baſe to the tip of the wing.

The wings are called plicatiles, when they are folded at the time the inſect is at reſt; planæ, when ſtretched out their whole length without folds, and incapable, from the ſtructure of their nerves, to be folded up; erectæ, ſuch as have an erect poſition when the inſect is at reſt, the ſuperior ſurfaces being brought in contact above the back, and the extremities oftentimes meeting, as in the butterfly tribe; patentes, thoſe like the geometra family of moths, and moſt of the libellula, which have the wings expanded horizontally when at reſt; incumbentes, ſuch as cover in an horizontal manner the ſuperior part of the abdomen, when the inſect is at reſt. Theſe differ from deflexæ, in having the outer edges declining towards the ſides, like the ridge of a houſe; reverſæ are alſo deflexæ, with this addition, that the edge of the inferior wings projects from under the anterior part of the ſuperior ones; dentatæ are thoſe with the wings indented or ſcolloped; caudatæ, thoſe in which one or more of the nerves of the poſterior wings extends beyond the margin, and forms a proceſs, ſuch as occurs in the equites family of papilio, and the genus heſperia, and in a far more remarkable manner in phalæna argus; reticulatæ, thoſe in which the veins or membranes of the wing form a kind of lattice-work, as in the genus libellula.

The colours (colores) are named in terms agreeably to their common acceptation; but according to the various forms of the ſpots, bands, ſtreaks, &c. in which they appear on the wings, they have various ſignificant appellations. Maculæ are ſpots; punctæ, dots; faſciæ, bands; ſtrigæ, ſtreaks; and lineæ, lines. Ocellus is a round ſpot, containing a ſmaller ſpot of a different colour in its centre. Stigmata is a term in the Linnæan language, introduced to ſignify a ſpot or anaſtomoſis in the middle of the wing, near the anterior margin: this is conſpicuous in moſt of the hymenoptera and neuroptera. Stigmates is a term alſo applied to the ſingle or double kidney-ſhaped ſpot ſituated in the middle of the anterior wings in many of the moth tribe, in the noctua family, and in ſome of the bombyces. Several modern naturaliſts call the reſpiratory ſpiracles at the ſides of the body in inſects ſtigmates, the application of which may create confuſion; ſtigmata, and ſtigma, ought for this reaſon to be admitted in the ſenſe Linnæus intended: the ſpiracles bear already a name ſufficiently indicative of their uſe and appearance, and do not require this alteration. Moſt of theſe terms apply only to the lepidoptera tribe, in the markings of whoſe wings the moſt beautiful colouring prevails.

Halteres, poiſers, or balancers, appendages peculiar to inſects of the diptera order, and which, with ſufficient reaſon, are deemed an eſſential character of that tribe. Theſe poiſers are two ſhort, moveable, clavated filaments, placed one contiguous to the origin of each wing. They ſeldom exceed one-tenth the length of the wing, though in certain genera they are rather longer. The capital, or head, in which the filament terminates is either roundiſh, oval, truncated at the end, or compreſſed at the ſides: in ſome inſects its ſituation is directly under a ſmall, arched, filmy ſcale, which alſo varies in ſize and form; and in ſeveral families is entirely wanting.

The exact purpoſe to which nature has deſtined theſe organs has not been hitherto aſcertained in a very ſatisfactory manner. The moſt prevalent, and perhaps in ſome meaſure the moſt conſiſtent, opinion ſeems to be, that they balance or counterpoiſe with the action of the wings, when the inſect is in flight, in the ſame manner as rope-dancers exerciſe a pole to preſerve their equilibrium. The diminutiveneſs of their ſize is a plauſible objection to this idea. Others conſider theſe as the organs of that vibratory ſound which dipterous inſects emit in flight: they compare the filmy ſcale to a kind of tambour, and liken the balancer to a drum-ſtick, which ſtriking repeatedly upon it, they conceive muſt occaſion this noiſe. In the conformation of the drum-like organs under the breaſt of ſome ſpecies of tettigoniæ, this conception is fully realized; a ſound is actually occaſioned by ſimilar means. (Vide Donov. Inſ. China.) But with regard to the diptera, it is apprehended the ſounds they emit in flight cannot be traced to this cauſe: in ſome we know it cannot, for the beſt of all poſſible reaſons, namely, that though, like others of the ſame tribe, they have balancers, they have no ſcale to ſtrike with them. It ſhould be obſerved alſo, that this buzzing ſound is obſervable in a vaſt number of inſects which have no poiſers or balancers, ſuch as waſps and bees. The two genera, aſilus and bombylius, have no ſcale, and yet the noiſe perceptible in their flight is louder than in moſt of thoſe which have both ſcale and poiſers, as in the muſcæ, for example. Nor does this noiſe iſſue from the poiſer, either by ſtriking on the ſcale, or by any other means, as muſt be admitted, ſince it is known that if the poiſers, or both poiſers and ſcales, be cut off, the ſame ſound continues to be heard from the mutilated inſects as before.

The motion of theſe poiſers, when the inſect flies, is very lively: they are longeſt in the tipula, diopſis, and aſilus; in muſca, ſcarcely apparent, and accompanied by a ſcale of large ſize.

Elytra, or wing-caſes, appertain to the coleopterous tribe: theſe are two in number, of a ſubſtance reſembling leather, for the moſt part moveable, and opening by a longitudinal ſuture along the middle of the back. The elytra are extended or raiſed up when the inſect is in flight. They do not appear to aſſiſt the inſect in its flight; the muſcles, by which they are connected to the body, have not their ſeat in the breaſt, like thoſe of the true wings; and its movement in the air is accompliſhed by means of the latter, which are tranſparent, folded between the body and elytra when at reſt, and expanded when the inſect flies. Some have the elytra united, and may with more propriety be named elytron, for it conſiſts only of a ſingle piece marked with a longitudinal line ſuperficially, inſtead of being divided by a ſuture; this is lifted up, or rather, the abdomen depreſſed downwards, to admit the paſſage of the wings laterally, when the inſect is preparing for flight. Others furniſhed with elytra, or wing-caſes, ſeem to render the term for theſe parts exceptionable; for in reality they have no wings beneath them: the number of theſe, however, is not conſiderable, and they cannot employ their elytra as organs of flight.

The ſuperior ſurface of the wing-caſes is more or leſs convex, and the lower ſurface correſpondently concave: the texture in ſome, as in ſome of the curculio and bupreſtis, ſo hard, that it is pierced with difficulty by means of a ſtrong pin; in others ſo flexible, that they ſpring into their proper form immediately after being bent double. The proportions of the elytra, compared with the body, are various, their form diſſimilar, and the diverſity of their ſurface, ariſing from dots raiſed or depreſſed, protuberances, flutings, colours, and other circumſtances, endleſs. Theſe differences in the elytra furniſh ſome excellent generical diſtinctions, and are ſtill more extenſively uſeful in conſtituting the characters of ſpecies. When the wing-caſes are ſhorter than the abdomen they are termed abbreviata, unleſs they terminate in a tranſverſe line, when they are called truncata; faſtigiata, when of equal or greater length than the abdomen, and terminating in a tranſverſe line; and ſerrata, when the exterior margin towards the apex is notched or ſerrated, as in ſome of the bupreſtis genus. The appearance of the ſurface is variouſly diſtinguiſhed; ſpinoſa is the term implying that the ſurface is covered with ſharp points or ſpines; ſcabra, rough; ſtriata, marked with ſlender furrows longitudinally; porcata, with elevated longitudinal ridges; ſulcata, with concave ridges, &c.

The want of appropriate terms for thoſe kinds of wing-covers, which partake of a middle texture between the elytra and the wings; and alſo for thoſe in which the characters of both are united, muſt be obvious in the preſent ſtate of entomology. To the firſt of theſe no ſuitable name has been given: the French "ètius molle," and "ètius preſque membranaceux," are not ſufficiently expreſſive; the firſt is deficient in preciſion, and in the other there is too much latitude. Linnæus once propoſed the term hemelytra, by which he intended to deſignate both kinds, whether, as in the grylli, thoſe parts were of an intermediate ſubſtance between leather and membrane; or, as in cimices and nepæ, one half was coriaceous, and the remainder membranaceous. The term, in this general ſenſe, could not be ſtrictly proper; it was, notwithſtanding, preferable to that of elytra, admitting the latter to be rightly applied to the wing-caſes of the coleoptera; and we are therefore the more ſurpriſed it was not afterwards adopted by that naturaliſt, or ſome other ſubſtituted. So lately as the tenth edition of the Linnæan Syſtema, the word elytra is employed indiſcriminately for the hard and ſtubborn wing-caſes of beetles, the ſoft wing-covers of the blatta, and the membranaceous reticulated wing-covers of the gryllus, all which genera were included at that time in coleoptera; and by an overſight equally extraordinary, the half-coriaceous wing-covers of the cimices, the nepæ, and notonectæ, were then confounded with the delicate covers of the aphis, thrips, and chermes, under the indiſcriminate title of wings. The diſtinction of coleoptera and hemiptera is rendered rather more clear in the laſt edition of that work, the blattæ and grylli being removed from the former to the latter order; yet the application of the word elytra to the wing-caſes of the hemiptera is not by that means rendered leſs improper. The difference in the conformation and conſiſtence of the wing-covers in the two tribes is too evident to leave this a matter of doubt. But cuſtom has ſo far ſanctioned this impropriety, that our beſt entomologiſts to this period deſcribe all theſe kinds of wing-covers under the name of elytra. Fabricius has not even attempted to correct this error in the Linnæan phraſeology: he adopts the ſame term.

Among the principal differences in the form and texture of the elytra, ſome, at leaſt, are very remarkable. In the beetle, or coleoptera tribes, theſe parts are coriaceous, very hard throughout, convex in form, and divided by a ſtraight ſuture. Thoſe of the cimex genus have the upper half only of a coriaceous texture, the lower half being ſoft and membranaceous, and the latter portion of one elytron is folded acroſs the correſponding part of the other when the inſect is at reſt. The coriaceous half of the elytra in many ſpecies is as hard and tough in texture as the entire elytra in the coleoptera, and the membranaceous part as ſoft as in the hymenoptera and diptera. In the genera blatta, forficula, acheta, and others, the elytra is of an uniform ſubſtance throughout, ſomewhat reſembling parchment; a ſimilar texture prevails in the elytra of nepa, notonecta, and naucoris genera, but rather like the cimices, there is a diſtinction between the upper and lower portions, the firſt being of a firmer texture, and thicker than the other part. The fulgora genus, like the gryllus, affords examples of another kind, thick, membranaceous, and ſtrongly reticulated elytra, divided in the middle by a longitudinal ſuture. In the tettigonia, another of the hemipterous genera, the elytra are often perfectly membranaceous and tranſparent in texture, though not in form reſembling thoſe of the hymenoptera and diptera; yet theſe are called elytra, and ſo likewiſe are the weaker and more flexible tranſparent anterior wings of the aphis, thrips, and chermes, for theſe two are included in the order hemiptera! From a due conſideration of theſe decided differences, we cannot heſitate to admit that the term elytra is not applicable to all. In a treatiſe of this kind it might, perhaps, create confuſion to introduce any other terms than thoſe in common uſe; we only intimate our perſuaſion, that reformation in the language of entomology is neceſſary. In the formation of any new ſyſtem, and which in the preſent ſtate of ſcience appears requiſite, we may reaſonably hope to ſee theſe and ſimilar objections obviated.

In concluſion of theſe remarks, it may be mentioned that nature has herſelf pointed out certain diſcriminating characters in thoſe parts called the elytra which do not ſeem to have been ſufficiently attended to, and which not only relate to their figure and appearance, but likewiſe to their utility, or the benefit the inſects derive from theſe organs. The wing-covers in the coleoptera do not, it is generally believed, in the leaſt degree, aſſiſt the inſect in flying: in the cimices, and others which have thoſe parts of a more flexible texture, they do not materially aid its celerity of motion in the air; but in thoſe which have the wing-covers completely ſupple, they concur immediately to its velocity in flight.

Sexes of Inſects.

The ſame difference of ſex exiſts throughout the inſect race as in moſt other animals. The ſexes cannot be aſcertained in the larva and pupa ſtate, except in ſome few inſtances; but when they arrive at their laſt ſtate, both kinds poſſeſs permanent characters, by which they may be eaſily determined: theſe conſiſt in a comparative difference in their ſize, and vivacity of colour, form of the wings, bulk of the abdomen, ſhape and dimenſion of the antennæ, and various other external peculiarities.

In moſt inſects the male is ſmaller than the female, their comparative difference varies conſiderably in different ſpecies. In the lepidopterous tribe the female is only perceptibly larger than the other ſex in general; in the ant it is ſix times larger than the male: in the coccus twelve or fifteen times, and in the termes the female is at leaſt two hundred times larger than the male. This latter ſex is commonly decorated with colours more lively and brilliant than the females, a diſtinction obſervable in a very remarkable degree in many of the butterfly tribe, the males of which are very beautiful, and the females obſcure. There is alſo ſome difference in colour between the two ſexes in ſome coleopterous inſects.

Many of the larger tribes of beetles (geotrupes) preſent a wide diſſimilarity in the conformation of the two ſexes: in the males the head is embelliſhed with one, two, or more diſtinct and prominent horns, and which, in a number of ſpecies, are very conſiderable in ſize; theſe are entirely peculiar to the males; the head of the female has only a few ſlight protuberances inſtead of horns, and is ſometimes even deſtitute of them.

In the moth tribe the antennæ of the male are almoſt invariably larger or more deeply pectinated than in the female, and this difference may be traced from the broad feather antennæ of the largeſt bombyces, to the ſetaceous antennæ of the noctuæ; however ſlightly the antennæ of the male appear pectinated, thoſe of the female will be found ſtill leſs ſo. The abdomen in this order is alſo ſmaller than that of the female. The colours of the wings alſo differ amazingly in the two ſexes, of which phalæna humuli (Linn.) affords a very ſtriking example, the wings of the male being of a beautiful ſnowy white; that of the female bright yellowiſh, with orange ſpots.

Another diſtinction, but which is not a general character, conſiſts in the female being apterous, or without wings, the male being furniſhed with thoſe organs of flight. Among the coleoptera we find the lampyris of this kind; in the hemiptera the blatta; among the moth tribe, phalæna antiqua, gonoſtigma, brumata, &c. Theſe wingleſs females are indeed ſo much unlike the other ſex, that no one unacquainted with inſects could believe them to be of the ſame ſpecies. The females of theſe lepidopterous inſects are not entirely apterous; they have four very minute wings attached to the thorax, in the ſame place as is occupied by the baſe of the wings in the other ſex, otherwiſe they reſemble an apterous inſect. In the aphis tribe the male has ſometimes wings, and is ſometimes without; and the female, it is ſaid, differs in the ſame manner.

Theſe are the principal external characters, by means of which the two ſexes in inſects may be diſcriminated.

Generation.

That general law of nature which prevails among the larger tribes of animated beings, and ordains an intercourſe of the two ſexes as indiſpenſable to the production of their young, does not regulate the multiplication of all inſects: there are ſome ſingular deviations to the contrary. The doctrine held by the ancient ſages of Egypt, that in certain inſects both ſexes are united, is perhaps inadmiſſible: we ought not to ſpeak with too much confidence on this ſubject, notwithſtanding the aſſurance of Linnæus, that there are no hermaphrodite inſects. The obſervations of naturaliſts leave us in no uncertainty with reſpect to another order of beings, namely, thoſe which belong to neither ſex; and indeed the exiſtence of theſe is demonſtrated daily in every hive of bees.

The myſteries of generation are only in part unveiled to the philoſophical enquirer. Some leading points appear equivocal, and remain inexplicable. This is the caſe with larger animals, where we have external circumſtances to direct our judgment. With reſpect to inſects, in particular, the hiſtory of their generation, in certain inſtances, at leaſt, is more obſcure. Many of them, like the larger animals, produce their young in conſequence of an immediate union of the ſexes. But among the numerous families which compoſe this extenſive claſs of creatures, there are ſome deviations from this ordinary courſe of nature, and theſe partaking of incidents ſo remarkable, that no poſitive and uniform concluſion of their mode of increaſe can be laid down. The notions entertained by ſome philoſophers in the middle ages, that inſects are the offspring of corruption and putridity, have no foundation in reaſon or analogy. It is impoſſible to conceive that organized bodies, poſſeſſed of life, and endowed with ſenſibility, can owe their origin to chance. But beyond this we are authorized in the belief of circumſtances, that militate very ſtrongly againſt eſtabliſhed opinions. The courſe of generation and mode of increaſe, obſerved in certain tribes of inſects, have no parallel among thoſe of the larger kinds of animated beings: we need only mention a few particulars of the aphides in ſupport of this.

Of the aphis genus there are not leſs than ſeventy ſpecies known, and the females of every one of theſe, ſo far as it has been poſſible to inveſtigate their manners, are capable of producing their young without the concurrence of the male ſex! A female aphis, brought up in the moſt perfect ſecluſion from the very inſtant of its production from the egg, will in the courſe of a few days be found in the midſt of a numerous family of females only, brought forth alive. An individual taken from theſe, or even ſelected at the moment of its birth from the brood, and kept alone, will in a ſhort time produce another brood, and in like manner a repetition of the ſame experiment will be again attended with the ſame reſults.

It would be only a natural inference drawn from the above mentioned circumſtances, that in the ſame individual of this kind the two ſexes muſt be united. This we know is not without example in the inferior order of animals, the greater part (we ſhall not ſay the whole) of the vermes tribe being probably of this deſcription. Such is not apparently the caſe however with regard to the aphis; the real truth appears ſtill more aſtoniſhing. To render theſe fertile, the intervention of the male ſeems to be requiſite in autumn, and hence the power of impregnation devolves down to the tenth, or, as ſome naturaliſts affirm, to the twenty-ſeventh generation. The eggs of the firſt, or parent brood, are laid in autumn, theſe hatch in the enſuing ſpring, and this fertile produce perpetuate the race through many generations till the autumn following; every brood, after thoſe hatched in ſpring from the egg, being viviparous.

The generality of vermes are believed to unite the two ſexes in the ſame individual, and thus poſſeſs the power of ſelf-production. Later obſervations ſeem to prove, that moſt animals of this tribe have both male and female organs, but that the union of two individuals are ſtill requiſite, each performing at the ſame time the office of male and female, and by this reciprocity of their functions both become fertile. Among the cancri, which Linnæus conſiders of the inſect race, we are aſſured ſome monſtrous luſi have been obſerved, in which the organs of both ſexes were apparent; but probably theſe might not poſſeſs the ability to perpetuate their natural race. Theſe we paſs over therefore for the preſent as irrelevant. There is no inſect, perhaps, ſuch accidents excepted, in which the two ſexes are united. We advance even this with caution, becauſe there is reaſon to imagine the contrary in certain inſtances. From our own obſervation we are perſuaded that ſome few at leaſt of the ſuppoſed vermes are the larvæ of genuine inſects. Let us for a moment imagine theſe larvæ to be really vermes! And let us farther conceive that theſe larvæ, like the true vermes, are of the hermaphrodite kind! What an extraordinary deviation from the uſual courſe of nature would ſuch a prodigy preſent!

Here, however, be it explicitly underſtood, that we do not aſſert the latter part of this obſervation as abſolutely certain. Such an aſſertion is countenanced by no opinion except our own, and ſuch opinion ought not to be advanced without being at the ſame time ſupported by argument and proof, the production of which would extend the limits of our obſervations very far beyond our preſent deſign. It is only our wiſh to intimate at this time, that there are certain animals of the ſuppoſed vermes, and which are deſcribed by Linnæus and others as appertaining to this claſs, which are in reality the larvæ of inſects; and that we are not without ſuſpicion that ſome of theſe larvæ are fertile, and produce an increaſe in a manner not very clearly known, before they aſſume their final form. Among the ſuppoſed vermes of the marine kind, the larvæ of certain coleopteræ will perhaps be recognized. Theſe are ſimply larvæ, and apparently deſtitute of any ſexual functions till they arrive at their laſt ſtate. Some of the freſh water larvæ, miſtaken for vermes, are in all probability of the ſame deſcription. But have we ſufficiently examined the inteſtinal vermes? Are any of thoſe peculiar to different animals, or man, capable of producing young vermes, like themſelves, and afterwards becoming inſects? One fact may be important, and we ſtate it upon the teſtimony of our own knowledge, that certain kinds of theſe ſuppoſed vermes, which infeſt the human race to the deſtruction of thouſands in the age of infancy, are really no other than the larvæ of inſects.

Linnæus affirms that no inſect can form an union with the oppoſite ſex, or propagate its kind till it arrives at the laſt ſtate, and offers this as a proof that gryllus pedeſtris is not a pupa which its appearance implies, becauſe it is found connected with the female. This obſervation of Linnæus is pretty generally correct, and it may be further added, that in the different ſtates, prior to the perfect condition, there are no ſexual organs, or at leaſt none that are developed. This is the fact with regard to moſt inſects, certainly not to all. Among the cimices there can be no doubt in our own mind from actual obſervation, that the ſemi-nymphs of certain ſpecies do unite with their mates, and afterwards become winged inſects. We are not without ſuſpicion that many of the grylli, like the pedeſtris, poſſeſs the ſame faculty, and are afterwards furniſhed with wings.

With reſpect to the inſects of neither ſex, or neuters, it ſhould be obſerved that thoſe appertain to ſpecies in which there are the two diſtinct ſexes beſides, as in the bee tribe. It is chiefly among the hymenopterous inſects that we meet with theſe neuters; the formicæ afford examples of other inſects of the ſame kind, and it is believed there are likewiſe neuters among the coleoptera. They are called neuters becauſe they are of no apparent ſex. Some have pretended that they are no other than females, in which the ſexual parts are not yet developed. This cannot, however, be the fact; neither can they be of the male ſex under the ſame diſguiſe, becauſe they are conſtantly diſſimilar in their characters from both, and could ſcarcely be ſuppoſed, from their appearance in many inſtances, to belong to the ſame ſpecies they really do, had not this been aſcertained by their production from the ſame brood with the two diſtinct ſexes.

Of inſects in general it may be obſerved, that the males and females of the ſame ſpecies are not unerringly faithful; they deviate occaſionally from the path appointed by nature. This is moſt obſervable in the coccinella genus. Theſe hybrid inſects are conceived to be unfruitful; they reſemble the female in form, but in point of colours and ſpots have ſome reſemblance to the male parent.

There is an accordance in the ſtructure and ſituation of the ſexual organs in inſects, whether male or female, with thoſe of larger animals, and their union is accompliſhed in the ſame manner. Theſe organs are uſually placed at the extremity of the abdomen. This is not conſtantly the caſe; there are inſects, and among thoſe the ſpiders, which have the male organs placed at the tip of the feelers, one at the extremity of each; every individual of theſe creatures being furniſhed with two. The female organ is beneath the abdomen. Another ſingularity is obſervable in the libellulæ (dragon flies), the males of which have the ſexual organ ſituated under the breaſt, while that of the female is at the extremity of the abdomen. When in union they are ſeen flying in the air, the female under the male with her ſlender body incurvated, and the tip of the abdomen bent under his breaſt.

Except at the period of their amours the ſexual organs of inſects are not perceptible, thoſe of the male at other times are drawn within the body. Their union in ſome ſpecies continues for a ſhort time only; others remain in this ſtate for hours, or even days together.

Transformation of Inſects.

Moſt animals retain during life the form which they receive at their birth. Inſects are diſtinguiſhed from theſe by the wonderful changes they undergo. The exiſtence of an inſect partakes of two, three, or four diſtinct ſtates, and in each of theſe differs moſt eſſentially in appearance, organization, and manners of living.

The ancients were not unacquainted with the ſingular metamorphoſes of inſects. Ovid has drawn many beautiful fables from this ſource. The ſongs of Anacreon afford certain paſſages to the ſame effect; and we might alſo mention others. An inquiry into the knowledge of the ancients in this reſpect might be intereſting; but we cannot now purſue the inveſtigation, as it would lead to digreſſions the limits of this article will not allow. Our ideas have been offered at ſome length in another place. (Donov. Hiſt. Inſ. China.) We ſhall only obſerve for the preſent, that they were not unacquainted with the metamorphoſes which certain inſects undergo. Their poets wantonly intermingled fable with truth, to improve their allegories; but their hiſtorians were more correct, and ſeldom formed erroneous concluſions, unleſs deceived by ſpecious appearances. In the ſixteenth century, with the revival of learning and philoſophical diſcuſſion, and from that period to the preſent, this ſubject has engroſſed much attention. The labours of Swammerdam, Goedart, Merian, Malpighi, and others, contributed materially to its advancement in the firſt inſtance. Their diſcoveries induced others to regard the transformations of theſe curious creatures with attention; and hence, in the courſe of years, their hiſtory became pretty generally underſtood. Thoſe who afterwards contributed moſt eſſentially to the improvement of this branch of entomological knowledge were Reaumur and Degeer. In the progreſs of time, other valuable works appeared in elucidation of the ſame ſubject. The moſt uſeful of theſe, perhaps, to the general reader, are thoſe denominated "Entomologi Topographici," or ſuch as relate to the inſects, with their tranſformations peculiar to, or inhabitants of particular countries. Among the number of theſe may be mentioned the two works of Merian, "Erucarum ortus, Alimentum et Paradoxa Metamorphoſis," and "Inſecta Surinamenſia." "Hiſtoire abregée des Inſectes, qui ſe trouvent aux Environs de Paris," by Geoffroy; "Naauwkeurige Waarneemingen," &c. of Admiral; Roeſel's "Inſecten Beluſtigung;" Abbot's "North American Inſects," by Smith; and Donovan's "Inſects of Great Britain."

The changes through which the greater number of inſects paſs are from the egg to the larva, from the larva to the pupa, and from the pupa to the laſt or perfect ſtate. Exceptions occur to this: for ſome inſects are viviparous; the number of theſe is not conſiderable: and there are others of the apterous or wingleſs kind, which undergo no change, iſſuing from the egg in the perfect form.

Of the Egg State.

The egg, containing the inſect in its ſmalleſt ſize, is expelled from the ovary as in oviparous animals. They are contained and arranged in the body of the inſect, in veſſels which vary in number and figure, in different ſpecies. The ſame variety is found in the eggs: ſome are round, others oval, ſome cylindrical, and others nearly ſquare. The ſhells of ſome are hard and ſmooth, while others are ſoft and flexible. It is a general matter of obſervation, that eggs do not increaſe in ſize after they are laid: among inſects we find, however, one exception to this rule, for the eggs of a ſpecies of tenthredo are known to become larger after being depoſited. The ſhell is membranaceous, which admits of this dilatation.

The eggs of inſects are of various colours; ſome are found of almoſt every ſhade of yellow, green, and brown, a few are red, and others black. Green and greeniſh are not unuſual, and they are ſometimes ſpeckled with darker colours, like thoſe of birds. Some are ſmooth, and others beſet in a pleaſing manner with little raiſed dots.

Inſects are inſtructed by nature to depoſit their eggs in ſituations where their young ones will find the nouriſhment moſt convenient for them. Some depoſit their eggs in the oak-leaf, producing there the red gall; others chuſe the leaf of the poplar, which ſwells into a red bladder: to a ſimilar cauſe we are indebted for the knob, which is often ſeen on the willow leaf, and the three-pointed protuberances upon the termination of the juniper branches. The leaves of the veronica and ceraſtium are drawn into a globular head, by the eggs of an inſect lodged in them. The phalæna neuſtria glues its eggs with great ſymmetry in rings round the ſmaller twigs of trees; others affix them to the ſurface of leaves; and again, others lodge them in the crevices of trees.

The gnat, the ephemera, phryganea, and libellula, hover over the water all day to drop their eggs: theſe hatch in the water, and continue there while in the larva and pupa form, quitting the water only when they attain the winged ſtate. The maſs formed by the eggs of the gnat reſembles a little veſſel, and floats on the ſurface. This inſect depoſits only one egg at a time; the firſt is retained by means of the legs, when dropped, till a ſecond is depoſited next to it, then a third, fourth, and further number, till the maſs becomes capable, from its ſymmetry, to ſupport itſelf upright. Many moths cover their eggs with a thick bed of hair or down, collected from their own body; others cover them with a glutinous ſubſtance, which, when hard, protects them from the ill effects of moiſture, rain, and cold. The ſolitary bees and waſps prepare neſts in the earth, hollow trees, or cavities in old walls, wherein they place a quantity of food for the ſupport of the young brood, when they break from the egg. Some of the ſpiders carry the eggs on their back in a ſmall ſilky bag. The ants are known to conſtruct neſts in the earth, in which their eggs are placed with the utmoſt care. Some depoſit their eggs in the larvæ of other inſects, chiefly thoſe of the moth and butterfly kind; and having paſſed through all their changes in their bodies, become what is termed the ichneumon fly. In the Lapland Alps there is an inſect called the rein-deer gad-fly (oeſtrus tarandi), the attacks of which are greatly dreaded by the rein-deer. It hovers all day over theſe animals, who betray every mark of fear; their legs tremble under them; they prick up their ears, and ruſh to the mountains covered with ice and ſnow, to eſcape from the fly, but often in vain; for the inſect follows, and generally finds means to lodge its egg in the back of the deer. The worm hatching penetrates the ſkin, and remains under it in ſecurity during the winter; in the year following it falls out, changed to a pupa, and becomes a winged inſect. The oeſtrus bovis is an equal terror to oxen; the hippoboſca equina to horſes; and oeſtrus ovis to ſheep: the latter inſinuates its eggs into the head of thoſe uſeful animals, through the naſal organs.

The neſt formed by the female of hydrophilus piceus, for the preſervation of their eggs, is altogether remarkable, and is deſcribed with much minuteſs by Lyonet. This neſt is whitiſh, its figure an oblate-ſpheroid, three-fourths of an inch in length, and its breadth two-thirds of its length; on the upper ſurface it is terminated by a lengthened horn-like proceſs, an inch long, ending in a point, and of a browniſh colour. In this neſt the eggs are depoſited, and left floating on the water till in due time they hatch, and the larvæ deſert the little bark contrived for their preſervation in the ſtate preceding, committing themſelves to the water. Theſe coques generally float among reeds and duckweed. The purpoſe of the conical projection is ſuppoſed to be that of ſuſtaining the caſe in an upright poſition, when aſſailed by the wind: but this is mere conjecture; we may have yet to learn its actual deſtination. Another aquatic inſect, (one of the nepa genus,) that inhabits the waters of China, exhibits a far more extraordinary inſtance of the parental care which the inſect race evince for the preſervation of their eggs. This diminutive creature, ſcarcely an inch long, and of a ſubrotund figure, with the upper and lower ſurfaces flattened, is ſeen at particular ſeaſons bearing a large cluſter of eggs on its back, which, though diſpoſed as compactly as poſſible, by being placed on one end, and having the ſides touching each other, cover no inconſiderable portion of the whole ſurface of the diſk. In this manner they are conveyed by the inſect, wherever it goes, till the larvæ hatch, and drop inſtinctively into the water; when the parent inſect caſts off the exuvia of the nidus, and reſumes its former appearance. (Donov. Inſ. China.)

Of all the productions of nature inſects are ſuppoſed to be the moſt numerous and fertile. With the exception of fiſhes and cruſtacea, they are apparently the moſt prolific. Lyonet has offered a curious eſtimate of the increaſe of inſects, taken from their eggs. From a brood of 350 eggs, which he obtained from a ſingle moth, he ſelected 80. Theſe, when arrived at their perfect ſtate, produced 15 females; and hence he deduces the following concluſion. If 80 eggs give 15 females, the whole breed of 250 would have produced 65. Theſe 65, if equally fertile, would have produced 22,750 caterpillars, among which there would have been 4265 females. Theſe, in the third generation, by the ſame mode of calculation, muſt amount to 1,492,750 caterpillars. The number would have been ſtill greater, if in the firſt inſtances a larger number of females had been ſelected.

Of the Larva State.

Coleoptera.—The larva of all the coleopterous tribes of inſects is produced from an egg, in which the growth of the creature in an embryo or infant ſtate may be eaſily traced ſome time previouſly to its birth. They are either of a heavy, ſlothful, and voracious diſpoſition, as may be obſerved moſt commonly of thoſe which paſs their lives under ground, in putreſcent ſubſtances, or the trunks of trees; or briſk and active, like the generality of thoſe in the ſucceeding or hemipterous order. Among the coleopterous larvæ of lively manners we muſt rank ſome of the terreſtrial kinds, which, though they live in the earth, are always found cloſe to the ſurface, and affect particular ſoils; and thoſe of ſands, in maritime ſituations eſpecially: to theſe we ſhould add the inhabitants of the watery element, or thoſe which, in the ſtate of larva, are of the aquatic kind; and in ſhort, all that are carnivorous: theſe being more remarkable for their activity than ſuch as are deſtined by nature to feed on plants only. A ſuccinct account of the larvæ belonging to a few of the principal genera, and a conciſe deſcription of their manners, will be ſufficient to afford an accurate idea of the modes of life purſued by the larvæ of coleopterous inſects in general.

We know nothing from actual obſervation of the larvæ, from which the larger kinds of extra European beetles are produced: the transformations of the ſpecies hercules, alcides, actæon, atlas, and goliathus, and a hoſt of other gigantic animals of the ſame kind, (the largeſt of the inſect race,) remain at preſent in obſcurity. Yet we are at no loſs to conceive what the appearance of ſuch inſects in the larva ſtate muſt really be, ſo far as we already know their affinities; becauſe, from analogy, we can conclude they muſt be ſimilar, or at leaſt, generally ſpeaking, we may preſume with ſafety they differ only in ſome ſlight degree. The transformations of the ſpecies naſicornis, a native of Europe, an inſect of large ſize, and from its conformation poſſeſſing habits ſimilar to ſome natural family of exotic beetles, will, for example, aſſiſt our concluſions as to thoſe reſembling it; and, in like manner, the transformations of other extra European kinds may be determined with ſome preciſion, from the known changes of thoſe inſects naturally allied to it, or, in other words, of the ſame natural family.

Scarabæus naſicornis, or, as it is ſometimes called, the rhinoceros beetle, from the conſpicuous horn placed erect on the head of the male, reſembles an extenſive family of ſcarabæi, the inhabitants of Aſia and Africa. The larva is hatched from an egg of a roundiſh form. The body is like that of a thick and ſomewhat broadiſh annulated worm, of a pale yellowiſh-white colour, flattiſh on the belly, and with the ſkin much wrinkled. The lateral breathing ſpiracles are very diſtinct, the head is hard and ſcaly, and armed with powerful jaws; and the three anterior rings of the body are furniſhed each with a pair of ſcaly jointed feet. It is found in the earth and in hollow trees, and ſeveral times caſts its ſkin before it changes into the pupa ſtate. The larva of the cock chafer, another of the ſcarabæi, (melolontha, Fabr.) reſembles this, except in being ſmaller: like the reſt of its family it ſpends the greater part of the time, while it remains in the larva form, in the earth, where it ſubſiſts on the roots of plants. It is two, and ſometimes three years in paſſing from the egg to the perfect ſtate.

The ſtag beetles, (lucanus,) in the larva ſtate, bear a ſtrong ſimilarity with the preceding; they reſide chiefly in rotten wood. The larvæ of ſome cerambyces reſemble theſe in being ſoft, and in having the head and feet ſcaly. It is the larva of an inſect of this genus (C. damicornis) which is eaten, and conſidered as a delicacy in the Weſt Indies. The ſpecies is a native of this and other parts of America, and it is credibly affirmed, on the beſt authority, that ſome people of fortune in the Weſt Indies keep negroes for the ſole purpoſe of going into the woods in queſt of them, and ſcooping them out of the trees. Their general length is about three inches and a half, and their thickneſs that of the little finger. Dr. Browne, in his hiſtory of Jamaica, particularly deſcribes this inſect; he informs us it is chiefly found on the plumb and ſilk cotton trees; that they are commonly called macaccos, or macokkos; and that the mode of dreſſing them, after opening and waſhing, is to broil them carefully over a charcoal fire. The epicures of theſe tranſ-Atlantic regions only imitate the epicures of antiquity: they alſo eſteemed the larvæ of the beetle tribe as a delicacy, and introduced them to their tables.

Many ſpecies of that elegant tribe of beetles, the curculiones, are the offspring of larvæ, bearing ſome reſemblance to the former: their body is covered with a wrinkled ſkin, their head with a ſcaly covering, and the three anterior rings of the body furniſhed each with a pair of feet. Theſe infeſt plants of various kinds; ſome ſubſiſting on the flowers, others the leaves, the roots, ſeeds, &c. One of theſe, the larva of curculio palmarum, deſerves notice for the ſame reaſon as that of cerambyx damicornis. This larva is about two inches long, and of an oval ſhape. It lives in vaſt numbers in the middle of the trunk of the young palm trees, and feeds on its juices. Theſe trees are ſometimes cut down, when about the height of a man, and the tendereſt part of them eaten; the worms are alſo taken care of, being conſidered as highly agreeable food when roaſted.

The larvæ of the coccinellæ have the body long, annulated, and furniſhed with ſix feet; they run briſkly over plants, and feed chiefly on plant lice. The larvæ of the genus caſſida are generally found under the leaves of plants on which they feed, to which they adhere by means of their lateral ſpines, and a briſtle at the end of their tail. They form a kind of umbrella with their excrement, under which they are ſheltered from the ſun and rain. The larvæ of the cicindelæ are ſoft and white, long ſix-footed, and have a brown ſcaly head. Theſe creatures employ great addreſs to entrap their prey: like the lion ant, in ſome degree, the larva lurks in a round perpendicular hole in the ground, with its head at the entrance, to draw in and devour whatever inſects come within reach. The larvæ of dermeſtes live in leather, fur, and other ſimilar ſubſtances, to which they do conſiderable miſchief. The larva of the ptini inſinuates itſelf into wood, and deſtroys it.

That ſimilarity in exterior characters, which we obſerve ſo prevalent in the perfect ſtate of all coleopterous inſects, whether of the terreſtrial or aquatic kinds, is not apparent in the larvæ of thoſe two natural tribes: they are in this ſtate altogether remote, and have no greater analogy in their conformation than in their manners of life, or the elements in which they exiſt.

The larvæ of the dytiſci conſtitute a link of beings cloſely allied to ſome of the neuroptera; and this reſemblance is ſo remarkable, that certain ſpecies of dytiſci and hydrophili in that ſtate differ more from each other than they diſagree with the larvæ of the libellula; theſe latter preſenting creatures of an intermediate character, and which, to an ordinary obſerver, would ſeem to unite them. Thus, the larva of libellula grandis more cloſely correſponds with thoſe of dytiſcus marginalis or punctulatus, than the latter with dytiſcus caraboides; and in external aſpect the affinity of the larva of dytiſcus caraboides may be even ſtronger towards that of ephemera marginata or hemerobius lutarius, than to either of the former. There is certainly a difference between theſe in the ſtructure of the jaws, &c.; but we ſpeak only of thoſe obvious characters and general appearances which firſt excite attention.

Dytiſcus marginalis, the ſpecies before mentioned, is common in many ſtagnant waters; and, from reſembling the ſhrimp in ſome diſtant degree, bears the name of ſquilla aquatica in the writings of Mouffet and Aldrovandus. It meaſures, when full grown, about two inches and a half in length, and is of a pale yellowiſh-brown colour, and very tranſparent. The head is large, ſomewhat flattened, and furniſhed in front with a pair of very ſtrong curved forceps, which, when magnified, are found to be perforated at the tip: theſe are the inſtruments with which it ſeizes upon its prey, and ſucks its animal juices. The legs are ſlender and ſmall in proportion to the body; the tail terminates in a trifurcated proceſs, ciliated at the margin. This larva is a fierce deſtructive creature, and not only commits vaſt depredations among the weaker kinds of water inſects, but preys alſo on the fry of fiſhes, and is for this reaſon highly injurious in fiſh-ponds. It is ſuppoſed, like ſome others of the ſame genus, to remain two years in the ſtate of larva. Dytiſcus cinereus is produced from a larva ſomewhat ſimilar, but remarkable for the length of the legs: its habits are the ſame. Caraboides is an hydrophilus, having the antennæ clavated inſtead of filiform; the body of the larva is ſhaped like the former, but on each ſide is a ſingle ſeries of plumoſe branchiæ, or breathing organs, like thoſe obſervable in the larvæ of ephemera marginata. In the firſt ſtages of growth this larva is fuſcous; when full grown, the poſterior part is greyiſh and rather pellucid. The gyrinus is another aquatic genus, and, from its form in the perfect ſtate reſembling the dytiſci, has been ſuppoſed ſimilar in that of larva; an argument, as already ſhewn, not always admiſſible. From the repreſentations given by ſome authors, it is not unlike that of H. caraboides, in the ſpecies natator, only of a more elongated form, and having four ciliated appendages at the poſterior end.

Hemiptera.—The larvæ of all hemipterous at preſent known are furniſhed with ſix legs, antennæ, and organs of the mouth, as in the perfect inſect from which they originate; and agree with them in moſt other reſpects, except in being entirely deſtitute of wings. The larvæ of the mantes are carnivorous; thoſe of the grylli feed on plants and farinaceous matter; the nepæ are aquatic, and ſubſiſt on water inſects; the cimices, inhabitants of the land, and a moſt extenſive tribe, are entirely carnivorous, and like that odious and well-known inſect of the ſame genus, (the common bug,) derive their ſuſtenance from the blood and juices, extracted by means of their proboſcis, from the bodies of other animals, thoſe of the largeſt kinds, and man not excepted.

Lepidoptera.—The caterpillars of the butterfly, ſphinx, and moth tribes form a very numerous ſeries; and theſe, from a variety of concurrent circumſtances, have been more particularly obſerved than any others. The greater part of thoſe lepidopterous inſects which come forth in the ſpring or ſummer periſh or diſappear at the approach of winter. There are few, the period of whoſe life exceeds that of a year. Some ſurvive the rigours of winter from being concealed under ground, and others remain hid in the bark of trees, or in the chinks of old walls, but the proportion of thoſe which out-live the inclemency of the winter ſeaſon is very inconſiderable, unleſs it be thoſe in the egg ſtate. Thoſe which are hatched in the autumn, and live under ground or in other places of ſecurity during winter, uſually come forth in the ſpring, take proper nouriſhment, and undergo their ſeveral changes to the perfect ſtate. The eggs, which have been carefully depoſited by the parent fly in thoſe places where they could remain in the greateſt ſafety, are alſo hatched in general by the genial influence of the ſpring, and the infant brood called into life and action.

All caterpillars are hatched from the egg, and when they firſt proceed from it are generally ſmall and feeble, but grow in ſtrength as they increaſe in ſize. The body of the caterpillar conſiſts of twelve rings; the head is connected with the firſt, and is hard and cruſtaceous. No caterpillar of the moth or butterfly has leſs than eight, or more than ſixteen; thoſe which have more than ſixteen belong to ſome other order of inſects. The ſix anterior feet, or thoſe next the head, are hard and ſcaly, pointed and fixed to the firſt three rings of the body, and are in number and texture the ſame in all lepidopterous larvæ. The poſterior feet are ſoft, flexible, or membranaceous; they vary both in figure and number, and are obſervable only in the caterpillar ſtate, the perfect inſect having only ſix feet, the rudiments of which are the ſix anterior ſcaly feet before-mentioned. Theſe ſpurious feet are either ſmooth or hairy, ſoft to the touch, or hard, like ſhagreen. On each ſide of the body are nine ſmall oval apertures, which are conſidered as the organs of reſpiration, and are called ſpiracles. The head is covered with a ſhelly ſubſtance, and on each ſide are five or ſix ſmall black ſpots, which are ſuppoſed to be the eyes. Some caterpillars grow to a very large ſize.

The caterpillar, whoſe life is one continued ſucceſſion of changes, often moults its ſkin before it attains its full growth. Theſe are the more ſingular, becauſe when it moults it is not ſimply the ſkin that is changed; for we find in the exuvia the ſkull, jaws, and all the exterior parts, both ſcaly and membranaceous, which compoſe its upper and under lip; its antennæ, palpi, and even thoſe cruſtaceous pieces within the head, which ſerve as a fixed baſis to a number of muſcles; we alſo find in the exuvia the ſpiracles, the claws, and ſheaths of the anterior legs, and in general the traces of all that is viſible in the external figure of the caterpillar.

The change in the caterpillar is effected by the creature withdrawing itſelf from the outer ſkin as from a ſheath, when it finds itſelf incommoded from being confined within a narrow compaſs. But to accompliſh this change is the work of ſome labour and time. Thoſe caterpillars who live in ſociety, and have a kind of neſt or habitation, retire there to change their ſkin, fixing the hooks of the feet, during the operation, firmly in the web of their neſt. Some of the ſolitary ſpecies ſpin at this time a ſlender web, to which they affix themſelves. A day or two before the critical moment approaches, the inſect ceaſes to eat, and loſes its uſual activity; in proportion as the time of its change approaches, the colour of the caterpillar declines in vigour, the ſkin hardens and becomes withered, and is ſoon incapable of receiving thoſe circulating juices by which it was heretofore nouriſhed and ſupported. The inſect is now ſeen at intervals with its back elevated, or with the body ſtretched to the utmoſt extent: ſometimes raiſing its head, moving it from one ſide to another, and then letting it fall again. Near the change the ſecond and third rings are ſeen conſiderably ſwollen. By theſe internal efforts, the old parts are ſtretched and diſtended as much as poſſible, an operation attended with difficulty, as the new parts are all weak and tender. However, by repeated exertions, all the veſſels which conveyed nouriſhment to the exterior ſkin are diſengaged, and ceaſe to act, and a ſlit is made on the back, generally beginning at the ſecond or third ring. The new ſkin may now be juſt perceived, being diſtinguiſhed by its freſhneſs and brightneſs of colour. The caterpillar then preſſes the body like a wedge into this opening, by which means it is ſoon torn down from the firſt to the fourth ring: this renders it large enough for the caterpillar to paſs through.

The caterpillar generally faſts a whole day after each moulting, for it is neceſſary that the parts ſhould acquire a certain degree of conſiſtency before its organs can perform their ordinary functions. Many periſh under this operation. The caterpillar always appears much larger after it has quitted the exuvia than before; for the body had grown under the old ſkin till it was become too large for it, and the parts being ſoft they were much compreſſed, but as ſoon as this ſkin is caſt off, the parts diſtend, and with them the new ſkin, which is yet of a flexible and tender texture, ſo that their increaſe in ſize at each moulting is conſiderable. Some caterpillars in changing their ſkin alter very much in colour and appearance, ſometimes the ſkin from being ſmooth becomes covered with hair, or ſpines, or tubercles, and others that are in one ſtage hairy, have the ſkin ſmooth in the next. No ſex is developed in the caterpillar ſtate.

The caterpillars of lepidopterous inſects ſeem deſtitute of all means of defence, and are the prey of birds and other voracious creatures. Nature has not, however, left the whole tribe in this defenceleſs ſtate, ſome kinds are armed with ſtrong and powerful ſpines diſpoſed in a verticillate manner round the annulations of the body, and which, if they be inſufficient to annoy others, ſerve at leaſt, in ſome meaſure, as the means of ſelf protection. There are others, chiefly the inhabitants of the warmer climates, whoſe bodies preſent an armament of ſpines not unlike that of the hedgehog or porcupine, and theſe placed in ſuch a formidable manner, as muſt either forbid the approach of other ſmall creatures, or puniſh their temerity. Some few of the North American ſpecies are of this deſcription. In others, we ſee the rings tuberculated, and every tubercle beſet with ramoſe ſpines, the branches of which intertexting with each other, form an almoſt impenetrable net-work of ſpines. Others again are thickly clothed with ſpines and hair intermingled, which may be ſufficient to guard them againſt the attack of ſome of their inferior enemies. Some ſpecies with the body covered only with a thin ſkin, and therefore apparently expoſed to the annoyance of every other, has the jaws ſo powerful, and the diſpoſition ſo ravenous and fierce, that they conſtantly attack, and moſt commonly with ſucceſs, the larva of other ſpecies much larger than itſelf. At the extremity of the body in the larva of the ſphinges, is a remarkable recurvate ſpine or horn, formidable in appearance, but harmleſs in its nature, and which is vulgarly ſuppoſed to be its weapon of defence. Theſe inſects, or at leaſt ſome of them, are not, however, without the means of annoyance, for it appears they poſſeſs the ability of diſcharging from their mouth or vent a fœtid liquor, the ſcent of which, ſhould it fall on the ſkin, cannot eaſily be removed even by waſhing, and which may be ſuppoſed powerful enough to repel other inſects. This ability in the ſphinx tribe of caterpillars is admitted on the authority of ſome credible authors; the like circumſtance is more commonly obſerved in the larvæ of ſome ſpecies of tenthredo.

The caterpillars of many inſects of the butterfly tribe feed cloſe to the ground, or under the ſurface, ſubſiſting on the lower parts or roots of plants; and for this reaſon many kinds are ſeldom ſeen, and others remain unknown. The larvæ of the ſphinx kind live chiefly on the leaves. Thoſe of the ſeſia genus are uſually denominated internal feeders, or ſuch as reſide in hollow cavities, which they form in the trunks or branches of trees, the ſubſtance of which alſo affords them nouriſhment. Many of the moth tribe are of the ſame kind, and have the ſame habits; others eat the leaves of different plants, and a few of the ſmaller ſorts feed on woollen, paper, and other ſubſtances, not of a vegetable nature. Some of the lepidopterous caterpillars are ſolitary, others live in ſociety.

Neuroptera.—The larvæ of neuropterous inſects are carnivorous, and in the vivacity of their manners exhibit a very ſtriking contraſt with thoſe of the generality of inſects. They are nearly all of the aquatic kind, paſſing their whole life, till they aſſume the winged ſtate, in the water; and are diſtinguiſhed for the peculiar addreſs with which they conſtantly wage war, not only againſt every other diminutive inhabitant of their natural element, but alſo againſt each other. Theſe larvæ are hexapode, or furniſhed with ſix feet of a ſcaly nature, and having the head protected by a ſimilar ſubſtance.

The libellulæ, or dragon-flies, form an intereſting genus of the neuroptera order, and the habits of their larvæ illuſtrate, in the ſtrongeſt manner, the nature of theſe aquatic creatures. The egg, when depoſited by the parent in the water, ſinks to the bottom, and remains there till the young inſect has acquired ſufficient maturity and ſtrength to burſt from its confinement. The larva, at firſt ſmall, increaſes to nearly half the ſize of the perfect fly, by changing its ſkin at different intervals like the caterpillars of moths and butterflies. The appearance of the little caſes containing the rudiments of the wings, at the lower margin of the thorax, denotes its change to the ſtate of pupa. The head of this larva is exceedingly ſingular, being covered with a maſk extending over the whole of the fore part of the head, with cavities in the interior ſurface to ſuit the different prominences of the face to which it is fitted with perfect neatneſs. Its form is triangular, growing ſmaller towards the bottom: in the latter part there is a knuckle which fits a cavity near the neck, and on this part it turns as on a pivot. The upper part of this maſk is divided into two pieces, which the inſect can open or cloſe at pleaſure, and it can alſo let down the whole maſk, ſhould occaſion require. The inner edges of theſe two pieces are toothed like a ſaw, and ſerve the animal as a pair of forceps to ſeize and retain its prey. This is the general principle on which theſe projecting forceps are conſtructed in the larva of the libellulæ; they differ in ſhape in the ſeveral ſpecies, but uniformly act in a ſimilar manner.

Theſe animals generally live and feed at the bottom of water, ſwimming only occaſionally. Their motion in the water can ſcarcely be called ſwimming, it is accompliſhed by ſudden jerks repeated at intervals. This motion is not occaſioned by their legs, which at this time are kept immoveable and cloſe to the body: it is by forcing out a ſtream of water from the tail that the body is carried forward, as may be eaſily perceived by placing them in a flat veſſel, in which there is only juſt water enough to cover the bottom. Here the action of the water ſquirted from their tail will be very viſible; it will occaſion a ſmall current, and give a ſenſible motion to any light bodies that are lying on the ſurface. This action can only be effected at intervals, becauſe after each ejaculation the inſect is obliged to take a freſh ſupply of water. The larva will ſometimes turn its tail above the ſurface of the water, and force out a ſmall ſtream, as from a little fountain, and with conſiderable force.

The larvæ of the ephemeræ, another of the neuropterous tribes, differ in various particulars from thoſe of all other inſects: its length, in the larger ſpecies, about an inch; the form rather long, and ſub-cylindrical, tapering a little towards the tail: the head is furniſhed with antennæ, trunk with ſix legs, abdomen with ſeveral finny plumes each ſide, and the tail with three long proceſſes. They live in the water, where earth and clay, it is affirmed, form their principal nouriſhment for the ſpace of two or three years, the time they conſume in preparing for their metamorphoſis, and which is accompliſhed in a few moments. The larva, when ready to quit that ſtate, ariſes to the ſurface of the water, and inſtantly caſting off its ſkin becomes a pupa. This is furniſhed with a kind of wings, by the aſſiſtance of which it eſcapes to the ſhore, and there ſettling, in the ſame moment, quits a ſecond ſkin, and becomes the perfect fly. In this ſtate, which has been ſo long preparing, the pleaſures it enjoys muſt be very ſenſible, if they are lively in proportion to the ſhortneſs of their duration, the inſect celebrating its nuptials, producing the fruit of them, and dying within the ſpace of a few hours; the vital principle, though ſo evaneſcent in the complete inſect, is extremely tenacious in the larva.

The phryganeæ, a genus of this order, very much reſembling in general appearance, certain families of the moth kind, are the offspring of aquatic inſects, not much unlike the larvæ above deſcribed; only that inſtead of inhabiting the waters in a defenceleſs ſtate, they conſtantly live in ſmall cylindrical caſes of their own conſtruction, which they drag after them in the water wherever they go. Theſe caſes are tubular and open at both ends: externally they are formed with ſmall bits of reed, gravel, ſmall ſhells, and other ſubſtances curiouſly cemented together, and lined with fine ſilk. The animal never quits its habitation till it becomes too ſmall for its body, when it conſtructs another. Like the hermit crab, when it is deſirous of moving from one place to another, the animal advances the fore-part of the body out at one end of the tube, ſo as to admit the free uſe of its legs, which are ſix in number, and placed contiguous to the head, and by this means it is able to crawl or walk with perfect facility at the bottom of the water. The body in moſt ſpecies is ſmooth, and the back uſually furniſhed with a tubercle, which prevents the caſe from ſlipping too forward while the animal is feeding, and which ſerves alſo to retain the caſe more firmly to the poſterior part of the body in the action of walking. Theſe, in common with other aquatic larvæ, are frequently uſed by anglers as bait, and are called cadew-worm, ſtone bait, or cod bait, and in the perfect ſtate is known by the name of ſpring fly. The larvæ of the phryganeæ prefer running waters.

Thoſe above-mentioned are the larvæ of the amphibious kinds of neuropterous inſects; there are others which live only on land, and differ much from theſe both in appearance and mode of life. Thoſe of the myrmeleon, panopa, hemerobius, and raphidia, are of the terreſtrial order. They are carnivorous as well as the aquatic kinds, preying on other inſects. The moſt extraordinary of theſe in their manners of life are ſuch as have been denominated by naturaliſts the lion-ants, or lion-piſmires (the myrmeleon of Latin writers). Of this genus there is nearly a dozen ſpecies, or, indeed, if we include the aſcalphi which Fabricius removes from that genus, there are altogether ſixteen ſpecies at preſent known. The larvæ of this family prey with the moſt ſavage ferocity on all the ſmaller kinds of inſects: it is not, indeed, this diſpoſition, ſo common to all carnivorous larvæ, that renders them remarkable, but the extraordinary and peculiar contrivances they adopt to enſnare their prey. We are beſt acquainted with the hiſtory of the ſpecies formicarius, the formica-leo of Linnæus, and this may ſerve as an example of the genus, the habits of which, ſo far as we are acquainted with them, being alike in all, with this difference, however, in their predatory powers, that formicarius is one of the ſmaller kinds, and leſs capable, from its inferiority in ſtrength and ſize, to commit devaſtation, than moſt of the extra European ſpecies, thoſe of Africa eſpecially.

Myrmeleon formicarius is found in France, Spain, and Germany, and is an inhabitant of ſandy places. The egg is depoſited by the parent inſect in the ſand, and this hatching produces a larva of an ovate form, armed with a long and powerful pair of jaws. The larva, as ſoon as produced, begins to exerciſe its talent of preparing a pitfall in the ſand, by turning itſelf rapidly round, and which, when formed, is ſomewhat funnel-ſhaped, or rather concave, with a very ſmall aperture in the centre under which the animal conceals itſelf with only its pincers advanced through the hole, ready to ſeize on any inſect that may unwarily fall into the hollow. Sometimes the whole head is protruded through the hole, but when it lies in wait the body is always concealed under the ſand. From the ſtructure of this trap, ſuch inſects as crawl to the edge or ſides are almoſt ſure to fall in, and be devoured by the larva. But ſhould the ſides of the pit not give way, or the unfortunate inſect appear to be able to make its eſcape, its mercileſs enemy immediately diſcharges from its head ſhowers of ſand, the repeated force of which is irreſiſtible; the inſect falls within reach of the larva, who, after ſucking out its juices through the tubular forceps, by a ſudden exertion throws the remains of its carcaſe out of the hollow to a conſiderable diſtance, and again, after repairing its den, renews its vigilance for prey. As the larva increaſes in ſize, it enlarges this cavity; at firſt it is only a ſlight depreſſion in the ſands half an inch in diameter, in its next ſtage it is increaſed to twice that diameter, and when the larva attains its full ſize is between two and three inches acroſs. In the preparation or enlargement of its pit, when it grows to its full ſize, it ſhews much addreſs: its operation commences by tracing an exterior circle of the intended circumference of the cavity, and continuing its motion in a ſpiral direction till it reaches the centre, thus marking each revolution in the ſand like the impreſſion of a large ſhell of the whorled kind, the breadth of each whorl correſponding with that of the inſect's body; and which, in the circumference of the whole cavity, amounts to four or five circles. After having ſufficiently deepened the cavity by a repetition of this motion, it ſmooths the ſides into a regular ſhape, by throwing out the ſuperfluous ſand by means of its forceps, which, when cloſed, together with the head, forms a convenient kind of ſhovel for the purpoſe. The grains of ſand thus diſcharged often fall to the diſtance of ten or twelve inches beyond the verge of its cavity. The depth of the cavity is uſually equal to its diameter. The ſingular larva, whoſe manners of life appear ſo intereſting when it has attained its full ſize, is about three quarters of an inch long, and has much the aſpect of a large ſpider in the form of its body: its head and legs more nearly reſemble thoſe of the pediculi of ſome particular animals, and are very ſmall, and in the ſtructure and proportion of the jaws or forceps its character is peculiar, theſe being enormous. Its general colour is pale reddiſh, very prettily variegated with diſtinct marks and ſpots of deep ferruginous both on the back and belly; the whole is beſet with a few hairs, ſome of which appear in tufts. It remains two years in the larva ſtate; in the ſummer it is active, but it is torpid during winter; when full grown it changes into a pupa, the animal previouſly enveloping itſelf in a round ball of ſand agglutinated and connected by a very fine ſilk, which it draws from a tubular proceſs at the extremity of the body: with this ſilk it alſo lines the internal ſurface of the ball. The complete inſect is furniſhed with four tranſparent ſpotted wings, and, like the larva, preys on inſects.

Hymenoptera.—The larvæ of the teredines bear the neareſt reſemblance poſſible to thoſe of ſome lepidopterous inſects, and have for this reaſon acquired the name of baſtard caterpillars, or falſe caterpillars; the ſpiral manner in which they roll themſelves up is one character that ſeems to remove them from the true caterpillar, but they are more clearly diſtinguiſhed by the number of feet, which, though varying in different ſpecies of both families, may be ſaid to be conſtantly more numerous in the tenthredo genus than in any of the lepidoptera orders. The firſt have from eighteen to twenty-two feet; the latter never more than ſixteen, including the ſpurious or poſterior ones. Theſe live chiefly on the roſe and willow trees. The larvæ of the ſirex genus is cylindrical, and furniſhed with ſix feet, and the head rounded; they perforate wood, and frequently eat their way into the bodies of other inſects, or their larva, and conſume their vitals. Theſe are the principal hymenopterous larvæ that are furniſhed with feet: the ſucceeding inſects are deſtitute of thoſe organs when in the larva ſtate.

One of the moſt curious tribes of larva among the hymenopterous genera are thoſe called the gall-flies; they are in no particular manner remarkable in appearance, but the effects they produce render them extraordinary. Every one muſt have obſerved thoſe vegetable excreſcences, of a globular form, which appear on the leaves and foot ſtalks of the oak at particular ſeaſons of the year, and which in autumn have acquired the ſize of a cherry or a ſmall plumb, its colour a bright red, and forming a pleaſing contraſt with the verdure of the leaves; theſe are the habitations formed by the punctures of the gall-fly, in which the eggs were depoſited each ſingly in its globule by the parent inſect, and each of thoſe excreſcences at this ſeaſon, on being opened, will be found to contain a larva; a ſmall worm of a cylindrical form and without feet. There are an amazing number of ſpecies of the gall-fly (cynips) that conſtruct their dwellings, and ſubſiſt on the juices of the oak, and many others that attack in like manner the maple and the willow. The larva is found like a nucleus, in a ſmall cavity immediately in the centre of each excreſcence.

The manners of the ichneumon, as popularly deſcribed, are fully known, and the hiſtory of the ichneumon flies ſeems to accord in a peculiar degree with all that has been fabulouſly related of the former. They are entirely paraſitical, and derive their ſuſtenance, till they arrive at the perfect ſtate, from the vital juices of other inſects. Their eggs are depoſited only in the bodies of other living inſects, generally thoſe of the caterpillar kind. The female, ſelecting her victim, faſtens upon it, plunges her abdominal tube into the body, and, in deſpite of all reſiſtance, maintains her hold till ſhe has lodged her ſtore of eggs. In the courſe of a few days the young larvæ, which reſemble minute maggots, are hatched. Theſe nouriſh themſelves with the juices of the caterpillar, which, notwithſtanding it affords ſuſtenance to the paraſitical brood, continues to move about, and feed till the time of its change into the chryſalis ſtate, when the larvæ creep out by perforating the ſkin in various directions, and form little oval ſilken caſes, the whole of which with the ſpinning forms an envelope to the withered remains of the inſect from which they derived nurture. The latter inevitably periſhes from the injury ſuſtained; in a ſhorter or longer period, according to the ſpecies, the ichneumons appear in a perfect ſtate. This paraſitical family, when produced, are found to be either entirely of the winged kind, or to conſiſt both of alated and apterous inſects, the females in certain ſpecies being deſtitute of wings. Theſe are, notwithſtanding, perfect inſects, as they never acquire thoſe organs afterwards, and being beſides, after an intercourſe with the other ſex, in a condition to depoſit fertile eggs, and thus perpetuate the breed. The apterous females attack caterpillars and other inſects in the ſame manner as the winged kinds, and depoſit their eggs in the living body.

So far as we are acquainted with the natural hiſtory of the ſphex tribe, the larvæ of theſe are lodged in the bodies of other inſects, in a manner ſimilar to that adopted by the ichneumons, with this difference, that the ſphex generally deſtroys the principle of life in thoſe creatures it attacks, inſtead of leaving them to linger through a tedious exiſtence of torture. Theſe inſects are very abundant in wood and hedges, and the larvæ feed chiefly on dead inſects, in the bodies of which they are produced from the egg. Some ſpecies dig holes in the earth with their fore feet, in which they bury their dead inſects, conſiſting chiefly of ſpiders and caterpillars, having previouſly depoſited their eggs therein; theſe holes are carefully cloſed with earth or clay, through which the larvæ force a paſſage when hatched. The larvæ are vermiform. The manners of theſe inſects is ſtrongly exemplified in the ſpecies figulus, a native of Upſal, and which is deſcribed by writers with conſiderable attention. This ſphex inhabits the holes in old wooden partitions, abandoned by other inſects, the interior of which the female cleanſes by gnawing the ſurface of the cavity throughout, and prepares it for the reception of her victim, by placing a piece of clay in the bottom. She then ſeizes on a ſpider, which having killed, and faſtened upon the clay, ſhe next proceeds to the depoſition of the egg, which is lodged in the dead body. This laid ſhe cloſes up the opening with clay. The larva hatched from the egg reſembles the maggot of the bee, and which, having devoured the food provided for it, ſpins itſelf a ſilken web, and changes to the pupa ſtate. In this manner each female inſect prepares ſeveral ſeparate holes, in each of which a dead inſect and an egg are depoſited. The larvæ of waſps and bees are ſoft, without feet, and feed on the nectar and honey collected by the parent inſects. The larvæ of the ants are alſo well known. The three latter mentioned families live in ſocieties, and with thoſe already noticed form the principal kinds of hymenopterous inſects.

Diptera.—Theſe larvæ vary much in different genera. Commonly they appear like a ſmall worm, the likeneſs to which is heightened by the animal having no feet, and in ſome ſpecies by the head being ſoft, like the body. Others differ in having the head ſcaly. The larva of the oeſtri, or gad-flies, depoſits its eggs in various parts of the bodies of cattle, which, when hatched, produce the moſt painful tumours. Some lay their eggs under the ſkin of cows or oxen, which they perforate for that purpoſe: others enter the inteſtines of horſes by the vent; and others, again, depoſit them in the noſtrils of ſheep. The larva of oeſtrus bovis is brown, and conſiſts of eleven ſegments, with tranſverſe rough interrupted lines. That of equi, known by the name of bots, depoſits its eggs on the hairs of horſes, and always on thoſe parts which are moſt likely to be licked with the tongue, and are thus conveyed into the ſtomach. The eggs of hæmorrhoidalis are laid on the lips of horſes, occaſioning a titillation, which cauſes the animal, when attacked by it, to move its head violently, and gallop about with every ſymptom of diſtreſs: this larva is carried into the inteſtines like the former, and is voided with the dung when its period of change to the pupa ſtate approaches.

In the genus tipula the larvæ are ſoft, cylindrical, and truncated at the head: theſe feed on the roots of plants. The larvæ of the different natural tribes, comprehended among the Linnæan muſcæ, exhibit ſome very diſſimilar appearances in form and habit. Generally, they poſſeſs a worm-like aſpect, ſometimes blunt at the anterior part, and acute behind, and at others pointed at both ends. Many live in watery places and devour inſects; others feed on decaying animal matter, or on the juices of vegetables. The larvæ of muſca vermileo preys on inſects, and in its mode of entrapping its prey imitates the manners of myrmeleon formicarius, like that ferocious inſect forming a circular den in the ſands which it inhabits, and watching in an aperture at the bottom for the unwary inſects that unfortunately wander too cloſe to its cavity. But of all the peculiarities related of the muſca tribe, nothing appears in any degree ſo extraordinary as the hiſtory of the larva of muſca tenax, recorded on the authority of Linnæus, and ſanctioned by that of Fabricius. The larva is repreſented as a brown maggot with a long tail, which latter is extenſile, and conſiſts of a double tube, the exterior annulated into numerous ſegments, and the interior ſlender and terminated by a circle of hairs, ſurrounding a ſpiracle. This maggot is ſeen in muddy ſtagnant waters, drains, and other ſimilar places; and is, according to Linnæus, a frequent inhabitant of the turbid pulp uſed in the operation of paper making. Hence it is often in this ſtate expoſed to the action of the wooden mallets uſed in this proceſs, as well as ſqueezed in the ſtrongeſt preſſes, and yet it ſurvives uninjured theſe ſeemingly deſtructive operations.

This circumſtance is deſcribed in a paper entitled "Miracula Inſectorum," inſerted in Am. Acad. 3. p. 331, and though purporting to be the production of Emanuel Avelin, obtained the ſanction of Linnæus. The ſame obſervation is confirmed in the "Syſtema Naturæ;" and is repeated in this place as a moſt extraordinary trait in the hiſtory of this inſect, without deeming ourſelves in the leſt reſponſible for its veracity.

The tabani nouriſh themſelves with the blood of horſes and cattle; and ſome think the larvæ are aquatic, though Degeer aſſerts they live under ground. The larvæ of culices (gnats) are very curious in their conformation: the body conſiſts of nine ſegments, which become gradually ſmaller from the head towards the extremity. The head is very large, and furniſhed on each ſide with a pair of pointed forceps, or hooks, with which it ſeizes its prey. The tail terminates in a tubular opening, at the tip of which are four ovate ſcales, two of which exceed the others in ſize. At the end of the body, near the tail, is a ſmall elevated reſpiratory tube, which the creature frequently raiſes above the ſurface of the water, while the head remains ſuſpended downwards. The colour of the larva is browniſh, extremely pellucid, and its motions remarkably lively. The larva, when firſt hatched, is extremely minute, and in the ſpace of fourteen days from its birth attains its full ſize, its length being then about half an inch. The painful ſenſation occaſioned by the ſting of the gnat, or, in other words, its ſucking proboſcis, is well known, and hence we are taught to conſider the gnat as an inſect ſubſiſting only on the blood of other animals: this is not, however, the opinion of ſome naturaliſts, who, reflecting on the myriads of theſe creatures, with which every watery place is infeſted, conclude they could not find ſufficient ſuſtenance, unleſs they ſubſiſted equally on the juices of vegetables and animals. Whatever may be the truth in this reſpect, the weapons of annoyance with which nature has furniſhed the larva indicate very clearly to us that in that ſtate, at leaſt, it is of the carnivorous kind. We ſhall laſtly mention the hippoboſcæ, a dipterous genus in the Linnæan ſyſtem, and which, unlike thoſe before adverted to, do not appear to have any larva; they are the produce of an egg which partakes of the two-fold character of being at the ſame time an egg and a pupa. The female, at diſtant intervals, depoſits an egg, which in magnitude is nearly equal to the whole bulk of its parent's body: the figure of this egg is oval, with an excavated depreſſion at the lower end; the colour, at its firſt excluſion, is milk white, except a large black ſpot on the fore part, from which it afterwards becomes brown, and then of a jet black, with a very high poliſh. This change in colour marks the progreſſive advancement of the inſect incloſed towards its maturity of formation, the parts becoming gradually developed. The egg depoſited in autumn acquires its deepeſt colour in the ſummer following, at which time the inſect burſts from its confinement in the winged form.

Aptera.—No inſect of this order, except the common flea, are ſuppoſed to undergo thoſe ſucceſſive changes which are uſual in moſt other inſects. They are almoſt entirely produced from the egg in their perfect form, and cannot therefore be ſaid to have any larva. In the flea, however, the ſmall worm which correſponds with the larva in other inſects is clearly aſcertained; and if we may place ſufficient reliance on the evidence of certain naturaliſts, one or two more of the apterous genera exiſt for a ſhort period in a ſtate ſomewhat analogous either to the larva or pupa. Leeuwenhoek obſerved that the mite was oviparous, laying very ſmall oval whitiſh eggs, from which proceeded the young animals, reſembling their parents in all reſpects, except in the number of their legs, theſe being only ſix in number, inſtead of eight; and after they caſt their ſkin another pair of legs appear, a fact that evidently implies two periods of transformation, the firſt of which may be compared with that of larva. An advancement, or progreſſive increaſe in the number of feet, is alſo well known to take place in ſpecies both of the julus and ſcolopendra genera, after they are produced from the egg ſtate. The julus ſabuloſus, when firſt excluded, is furniſhed with three pair of legs, which are ſituated at each ſide near the head: ſome days after about fourteen become viſible, and the remainder, to the amount of one hundred and twenty on each ſide, are gradually acquired afterwards. The ſame remark will apply to certain ſpecies, if not the whole of the ſcolopendræ genus. Scorpions are produced by the female parent in a living ſtate; they are at firſt very ſmall and white, and become of a darker hue in a few days: theſe, like the ſpiders, caſt their ſkin as they increaſe in ſize.

Of the Pupa ſtate.

By this term, as underſtood in the very extenſive ſenſe Linnæus propoſes, we comprehend that ſtate of an inſect which ſucceeds the larva and precedes the pupa, without any regard to the particular appearance it aſſumes in this ſtage of transformation. From this latitude of meaning it includes, therefore, with equal preciſion, and no leſs propriety, ſtates of the moſt diſcordant character. It alike implies the uncouth grub incaſed in its ſhelly repoſitory, and immured in the earth, ſluggiſh, almoſt deſtitute of motion, or the appearance of any other animal function, with the lively half-winged locuſt, or the cicada, animals ſporting in the full enjoyment of life. The bot, impriſoned in its oval covering, without the leaſt external ſign of animation, is termed a pupa. The moth, quieſcent and abſtinent for months, concealed in its ſhelly covering in the earth, or ſuſpended aloft in its ſilky envelope to the branch of a tree, is a pupa; and we denominate thoſe pupæ alſo which have the wings only half expanded; though, like the nimble-footed cimex, they are perpetually roving, and deriving ſuſtenance from the blood of other animals; and ſo alſo the reſtleſs libellula, which is continually traverſing the watery element, with the facility of fiſhes in ſearch of prey. Surely the difference between theſe is too great to be defined by any ſingle term.

Writers have obſerved, that before the time of Linnæus this ſtate of transformation was known only by the term chryſalis, a word derived from the Greek, and expreſſive of that golden luſtre peculiar to certain butterflies; but this appearance not being general, the word was changed by Linnæus to that of pupa, in alluſion to the indiſtinct reſemblance which many inſects in that ſtate bear to a child ſwathed or dreſſed in ſwaddling clothes. Theſe obſervations are certainly incorrect, for the word nymph, implying exactly the ſame fanciful compariſon, was in uſe before the time of Linnæus; the earlier authors ſo named one particular tribe of inſects in this ſtate, namely, thoſe having all their limbs incloſed within a ſkin: Linnæus adopted the idea but changed the word to pupa, and aſſigned it indiſcriminately to all inſects in that period of transformation from which the perfect fly is produced.

If we take a retroſpective view of the ſtate of entomology before the time of Linnæus, and conſider attentively the terms by which the different ſtates of inſects were then known, there does not appear much reaſon to commend the alterations which he has introduced. From the labours of Swammerdam, Reaumur, Roeſel, Liſter, Ray, and others, the transformations of inſects were then generally known, and particular terms had become eſtabliſhed by which the ſeveral ſtates, appearances, &c. might be diſcriminated. Theſe were not ſufficiently numerous, and of thoſe in uſe ſome were leſs expreſſive than could be wiſhed; but it is ſtill not to be concealed that ſome, at leaſt, were preferable to thoſe introduced by Linnæus. This is the more to be regretted, as Linnæus wrote under favourable circumſtances, and on his authority the introduction of a few expreſſive terms would have been attended with particular advantage. For inſtance, we ſhould have conceived it deſirable if he had deſignated this ſtate of inſects, which he calls pupa, by different terms, applying to each particular family a name at once expreſſive of their ſtate, and the order to which they belong. When, in the works of his predeceſſors, we read either of the aurelia, nymph, or ſemi-nymph, we know that in a word it implies the ſame ſtate as Linnæus means by pupa, with this additional information, that it is either of the dormant kind, like the moth, or active, like the nepæ, &c.; the Linnæan name conveys no ſuch additional information; it applies without diſtinction to all, and merely intimates its ſtate of transformation.

Perhaps the alteration of the word chryſalis to pupa may be thought by ſome an amendment; we do not diſapprove of it, but object to the very indiſcriminate ſenſe in which it is employed. As it applies to the nymphs of one family deſcribed by earlier writers, it is admiſſible; to others it is not. Or if the term pupa were adopted in its moſt extenſive ſenſe, to comprehend this ſtate throughout the whole race of inſects ſubject to this period of transformation, the want of terms to diſtinguiſh the particular tribes of which they conſiſted would be equally felt. The general manner in which the term pupa is applied by Linnæus, and the inconſiſtency attending it, cannot be more fully exemplified than by the following circumſtance. Linnæus, we are told, changed the word chryſalis to pupa, becauſe the former implied a golden appearance not obſervable in all the ſpecies; yet he applies the word pupa, which he defines as alluding to the appearance of a child in ſwaddling clothes, ſuch as we ſee in the moth and butterfly tribe, to the blatta, gryllus, cimex, and a hoſt of other active creatures which exhibit no ſuch reſemblance, and which bear no relation whatever to the others either in manners or aſpect! The firſt of theſe were called by old writers nymphs, the latter ſemi-nymphs; but theſe diſtinctive terms are confounded by Linnæus under the ſingle term pupa. Surely the impropriety is as great in the alteration made as in the error it is deſigned to remedy.

To obviate, in ſome degree, the confuſion ariſing from this general adoption of the word pupa, Linnæus propoſed afterwards to divide them, according to their form, into five families, to each of which he aſſigns a trivial or ſecondary name.

Theſe diſtinctions are not objectionable, but are rather too few in number, and they are certainly not expreſſed in terms ſuitable for general uſe. Nor does Linnæus himſelf appear ſatisfied with them, for although they are inſerted with definitions at ſome length in the "Fundamenta Entomologia," they are not adopted in the "Syſtema Naturæ," and are for this reaſon rather to be regarded as matter of curioſity than of utility. The pupæ are divided into ſections, according to the following circumſtances. When confined in a caſe of a globular form, which has no reſemblance to the inſect it contains, it is called coarctata, or ſtraightened, the examples of which are the muſci and oeſtri; obtecta, diſguiſed or ſhrowded, when the inſect is wrapped up in a ſhelly covering of ſuch a form that the part which contains the head and thorax may be diſtinguiſhed from that wherein the abdomen is lodged, as in lepidopterous inſects. It is termed incompleta when the pupa has perceptible wings and feet, but cannot move them: ſemi-completa, theſe can walk or run, but have only the rudiments of wings. The difference between the pupa and the larva of this claſs is very inconſiderable; in the firſt ſtate they have no wings, and in the pupa the wings begin to be developed as in the graſshopper: completa, in which the egg may be conſidered analogous to the pupa, the inſect being produced in its perfect form from the egg without paſſing through any other change.

Swammerdam divides inſects into four claſſes, the characters of which are founded principally upon their appearance in this ſtate of transformation, and the particulars attendant thereon.

The firſt of theſe comprehends thoſe inſects which, after being fofmed in their egg without the aid of food, and which, after having acquired, by the evaporation of the ſuperabundant humidity, the neceſſary conſiſtency, quit that ſtate, and iſſue from the ſhell under the form they are to retain during life, without undergoing any other transformation, as inſtanced in the ſpider.

The ſecond conſiſts of thoſe inſects which, after leaving the egg, are without wings, but with all the other members, as in the perfect inſect; in this ſtate they eat and grow, paſs into the nymph form, and from that iſſue with perfect wings, and with the ability to propagate their ſpecies. The dragon flies, graſshoppers, and cimices are of this family.

The third includes all kinds of butterflies and moths. They iſſue from the egg which lay in a diſguiſed ſtate and without food; the ſecond ſtate eats and grows, and the members of the animal into which it is to be transformed are formed under the ſkin, which it at laſt quits and becomes a nymph, and then after the evaporation of the ſuperfluous humidity produces the perfect inſect.

The fourth family, after having arrived at the nymph ſtate, like thoſe before-mentioned, does not diveſt itſelf of the ſkin in order to enter into that ſtate, but aſſumes the form of a nymph under its ſkin, where it continues ſhut up, till quitting two ſkins, at once it comes forth in its perfect ſtate. This is the metamorphoſis which ichneumons undergo. Theſe are the four families into which Swammerdam divides inſects, and the explanations he affords; and theſe, with ſome improvements and modifications, form the baſis upon which the pupæ are arranged by many of the continental naturaliſts at this time.

The following obſervations on the ſame ſubject by Lyonet deſerve attention. "By the term nymph (ſays this writer) is meant a ſtate of imperfection, attended ſometimes with inactivity, inaction, abſtinence, and weakneſs, through which the inſect paſſes, after having attained a certain bulk, and in which its body receives the preparatives neceſſary for its paſſing to a ſtate of perfection, all the external parts of the inſect are then found enveloped, either with their natural ſkin, or with a fine membrane, or with a hard and cruſtaceous cruſt. In the firſt caſe the limbs of the inſect remain free, it preſerves its power of acting, it eats, and its form is little different from what it was before. In the ſecond caſe the limbs of the inſect are folded over the breaſt but ſeparate; it can neither eat nor act, it retains hardly any traces of its former figure, and has only a confuſed reſemblance to that which it is going to aſſume. In the third caſe, the cover brings all theſe parts of the animal into one maſs; it makes it equally incapable of eating and acting; it has no reſemblance either to what it formerly was, nor what it is to be. Theſe three ſorts of change are evidently very different, and yet we have only two words in our language (French) to diſtinguiſh them by. We ſay of the inſects in the two firſt caſes, that they are changed into nymphs, and of thoſe in the laſt caſe that they have aſſumed the form of chryſalids. To theſe terms it would be proper to add a third, in order to mark the difference between the two firſt. It might be done I think very conveniently by allowing the laſt to retain the name of nymph, and calling thoſe of the firſt kind ſemi-nymph, or demi-nymph, a name which would not perhaps be inapplicable to them, conſidering the ſmall degree of change they have undergone. Graſshoppers, which, inſtead of the long wings they acquire, have ſtill only on their backs the ſmall caſes in which theſe wings are formed, are nymphs of this kind; they may properly be called ſemi-nymphs. Thoſe who have had an opportunity of examining a bee hive, cannot fail to have remarked bees ſtill imperfect in the ſhut cells; theſe are the nymphs of the ſecond order. The ſilk-worm furniſhes a well known example of inſects under the form of chryſalis.

"Inſects which undergo no other metamorphoſis than that which has converted them from the ſoft ſubſtance of an egg to a well formed and living body, are thoſe which conſtitute the firſt claſs of transformations ſpoken of. They increaſe in ſize, the greater part caſt their ſkin; ſome of their parts acquire greater ſize than the reſt, and ſometimes take a different colour from what they had before. This is almoſt the only change they undergo. The tranſformations of the inſects of the other three claſſes do not terminate here; after having caſt off their ſkins for the moſt part ſeveral times, and after having acquired their deſtined bulk, all become either ſemi-nymphs, nymphs, or chryſalids. They paſs a certain time under this form, and upon quitting it aſſume that of a perfect inſect, capable of generation. It is from the diverſity which takes place in theſe three ſorts of changes that the principal characters, which diſtinguiſh the inſects of the ſecond from thoſe of the third, are taken."

The inſects of the ſecond claſs are thoſe that paſs through the ſtate which Lyonet calls ſemi-nymphs. They do not undergo a transformation which is entirely complete, but in their laſt change they have ſtill generally all the members they had before, without having acquired any others, except they have wings; and as already remarked the ſemi-nymph differs very little from the animal which produced it. What always diſtinguiſhes it is, that there are ſeen upon its back at the baſe of the thorax the caſes in which the wings are formed, which before that appeared but little, and often not at all. In other reſpects it walks, runs, leaps, and ſwims as before. The difference between the ſemi-nymphs, and the winged inſect which it produces, is not always ſo obſcure. In ſome ſpecies it is ſo large that it is with difficulty we can diſcover its firſt form. But the greater part in their laſt ſtate differ chiefly in the wings.

The inſects of the other two claſſes do not enjoy the ſame advantages as the other. They loſe the uſe of all their members when they enter upon their transformation, and have no reſemblance to what they were before. An animal of theſe two claſſes which before had no legs, or had five, ſix, ſeven, eight, nine, or ten pairs, has now no more than three pairs, which, with the wings and antennæ, are folded up under the breaſt and remain immoveable.

What diſtinguiſhes theſe two laſt claſſes from each other is, that the inſects of the third claſs quit their ſkin, when they change into nymphs or into chryſalids, and that thoſe of the fourth change into nymphs under their ſkin, which hardens round them, and forms a caſe.

Reaumur found, in the transformation of inſects of the fourth claſs, a character that ſeems to diſtinguiſh it eſſentially from the reſt, namely, that they changed into nymphs without quitting their ſkin. He diſcovered that they undergo one transformation more than other inſects; becauſe before they become nymphs, they aſſume under their ſkin an elliptical form, or that of an elongated ſpheroid, in which no part of the animal is diſcernible; that in this ſtate the head, thorax, wings, and legs of the nymph are incloſed in the interior cavity of the abdomen, from which they iſſue ſucceſſively by the anterior part, nearly in the ſame manner as the extremity of the finger of a glove, which has been drawn in, is puſhed out again. Thus, the inſects of this claſs are not ſolely diſtinguiſhed from others by their changing into nymphs under their ſkin, but principally in undergoing a double transformation before they become nymphs.

Bergman diſtinguiſhes three kinds of pupa, which he calls chryſalids, nymphs, and ſemi-nymphs. The firſt he deſcribes as hard and motionleſs, that does not eat, and ſhews obſcurely the members of the future inſect; the nymph is tender, lying at reſt, not eating, and which ſhews clearly the ſeparate members of the future inſect; the ſemi-nymph is furniſhed with legs, and runs, eats, and is hardly different from the larva, except in having the rudiments of the wings, which the larva wants.

This inquiry, if duly purſued, would lead to much farther digreſſion. From what is already advanced we preſume it will be apparent, that the writers prior to the time of Linnæus, or cotemporary with him, (for thoſe alone are mentioned,) are not agreed in their manner of diſtinguiſhing inſects in this third ſtate of transformation; and that their appearance is ſo various in different tribes, while in this ſtate, that they ought to be diſtinguiſhed by ſeveral, inſtead of a ſingle name. Fabricius, one of the moſt conſiderable entomological writers ſince the time of Linnæus, employs the word pupa in the ſame general ſenſe as the latter; but he is the principal late continental writer worthy of conſideration, who has imitated this example. The French naturaliſts chiefly follow Lyonet, with ſome ſlight variation. This arrangement is ſtill ſuſceptible of much improvement, but is notwithſtanding perhaps the moſt perſpicuous yet propoſed. To the chryſalis properly ſo called, namely, thoſe of the butterfly tribe, this name given to them by the Greeks is retained; the reſt of thoſe which have their members enveloped in a common ſkin are called nymphs, and are divided into three or four families, according as thoſe parts are more or leſs viſible through the exterior membrane. The term féve (bean) is alſo introduced, to expreſs in a general manner this ſtate of the inſect, when of an oblong form, and diſtinguiſhed only by a few annulations and eminences. Inſects in the third ſtate, which differ only from the perfect form in having half-wings, are called ſemi-nymphs.

In the preſent ſection, to avoid confuſion, it may be more convenient to adopt the Linnæan term, and under this head deſcribe ſuch of the leading differences in inſects as are obſervable in this ſtate of transformation.

Coleoptera.—The nymphs or pupæ of this order have commonly the limbs detached or not laid under the exterior envelope cloſe to the body, as in lepidopterous inſects. Moſt of them bury themſelves in the earth previouſly to this change; ſome form cells in decayed trees, others perforate ſeeds and nuts, and great numbers remain in the dung of animals, or other filthy ſubſtances, where the larvæ have been nouriſhed. Their appearance, while in this ſtate, is nearly the ſame in all, an emollient pupa of a whitiſh colour tinged more or leſs with browniſh, and in form remotely reſembling that of the moth kind, but with the limbs diſtinct. The mutations of ſcarabæus naſicornis affords an intereſting deſcription of the pupa of a coleopterous inſect, and may ſerve as an example for the reſt of the tribe. When the time approaches for this larva to change into the pupa form, it penetrates deeper into the ground than the larva had done before. Having found a proper place, it forms with the poſterior feet a poliſhed cavity, in which it remains for ſome time immoveable; after this, by voiding excrementitious ſubſtances, and the evaporation of moiſture, it diminiſhes in ſize, and the ſkin becomes furrowed and wrinkled, as if the animal were partly ſtarved. If diſſected at this time, the head, belly, and thorax may be diſtinguiſhed. While ſome external and internal parts are changing by a ſlow accretion, others are gently diſtending by the force of its impelled humours. The body, contracting itſelf while the fluid is propelled towards the fore parts, forces the ſkull open in three parts, and the ſkin in the middle of the back is ſeparated by means of an undulating motion of the inciſions of the back; at the ſame time the eyes and the horns, &c. caſt off the exuvia. During this operation, a thin watery humour is diffuſed between the old and new ſkin, which renders the ſeparation eaſier. The proceſs going on, the larva is at laſt diſengaged from its ſkin, and the limbs and parts are by continual unfolding transformed into the pupa ſtate: after which it twiſts, and compreſſes the exuvia at the vent, and throws it towards the hinder parts under the belly. The pupa is at this time very delicate, tender, and flexible, and affords a curious ſpectacle.

The pupa of this beetle weighs, a little time after its change, much heavier than it does in the beetle ſtate, which is alſo the caſe with the bee and the hornet, which latter have been known to weigh ten times as much as the inſect when perfect. If the ſkin be taken off at this time, many curious circumſtances may be noted, but what claims our attention moſt, is, that the horn which is ſo hard in the male beetle when in a ſtate of maturity, that it may be ſharpened on a grind-ſtone, in the pupa is quite ſoft and like a fluid. How long this particular remains in this ſtate is uncertain, ſome beetles of the ſame kind reſt in this form the whole winter, more particularly thoſe who quit the larva ſtate in autumn. Some beetles go through all the ſtages of their exiſtence in a ſeaſon, while others remain two or three years even in the pupa ſtate.

When the proper time for their final change arrives, all the muſcular parts grow ſtrong, and are thus able to ſhake off their laſt integuments, which is performed exactly in the ſame manner as in the paſſage of the inſect from the larva to the pupa ſtate, ſo that in this laſt ſkin, which is extremely delicate, the traces of the pulmonary tubes that have been pulled off and turned out again become viſible.

Hemiptera.—The pupæ in this order are the ſemi-nymphs of the old writers, and reſemble the perfect inſect in ſize and figure, but are without wings. The rudiments of theſe members, of larger or ſmaller dimenſions in different ſpecies, are ſituated at the poſterior parts of the thorax. They have the ſame manners, and ſubſiſt on the ſame food as the perfect inſects; and we have reaſon for ſuſpecting that ſome at leaſt of theſe are not deficient in any of the animal functions.

Lepidoptera.—When the caterpillar of a butterfly or moth has attained its full growth, ſome writers affirm, that the rudiments of the perfect fly may be diſtinguiſhed upon accurate inveſtigation beneath the ſkin. This is aſſerted by Swammerdam, who declared he could demonſtrate all the parts of the future butterfly in a caterpillar near the change. To diſcover this, it is directed, that the caterpillar be taken at the time the ſkin begins to open, when it is to be drowned in ſpirit of wine or ſome ſtrong liquor, and to be left therein for ſeveral days, that it may take more conſiſtency and harden itſelf, the ſkin of the caterpillar muſt be then removed, which will be eaſily accompliſhed, and the incloſed moth will appear. The rudiments of the future inſect are extremely tender, and ſhould be touched with the utmoſt delicacy, when the legs, antennæ, and other parts, may be unfolded and diſplayed to view. The parts of the moth or butterfly are not exactly diſpoſed in the ſame manner in the body of the caterpillar, as when left naked in the chryſalis. The wings are ſaid to be longer and narrower, being wound up in the form of a cord, and the antennæ are rolled up on the head, but in a very different manner from what it is in the perfect inſect, and different from that in which it lies in the chryſalis; ſo that it is by a progreſſive and gradual change that the interior parts are prepared for the moth and pupa ſtate; and even the eggs, hereafter to be depoſited by the perfect animal, are to be found both in the caterpillar and pupa, the whole arranged in their natural and regular order.

Many of the chryſalides of the butterfly tribe poſſeſs a peculiar luſtre in colour and brilliancy, reſembling gold. It is not an appearance common to all butterflies, it is confined to certain ſpecies, and is not ſeen in any of the pupæ belonging to the moth tribe. This colour does not appear immediately in the chryſalides, but is aſſumed by degrees as the incloſed inſect acquires conſiſtency. It owes its ſplendour to the luſtre of the white or light colour of the incloſed animal ſhining through the yellow tranſparent membrane of the caſe, as M. Reaumur has deſcribed in his work. This metallic appearance ſeems to have afforded a favourable pretext to the alchemiſts of former days, who were weak enough to draw deluſive hopes from this appearance, and conceive it would afford them gold.

The following very curious and indeed inſtructive deſcription of the chryſalis of a butterfly is given by our countryman Liſter, nearly half a century before the ſcience of entomology had made any conſiderable progreſs on the continent of Europe, and from which it would appear, that in his time the knowledge of that ſcience was in a great meaſure confined to this country: it is from his annotations on the works of Goedartius.

"The middle ſtate or diſguiſe of a butterfly is called by the Greeks chryſalis, or a thing gilt, as the word importeth: the Latin hath left us no name that I know of: we have tranſlated it aurelia. The Latins, however, call the caterpillar eruca; which is a word (as I gueſs from a place in Vitruvius), which ſignifies in the old Tuſcan language viride æris, and thence borrowed to ſignify a caterpillar: for ſome caterpillars there are, which I have ſeen in Languedoc feeding on a certain common tithymal, very notably painted with a ſea-green colour, or blue. So that as the gilding of ſome few chryſaliſes gave a denomination to all; in like manner, the blue colour of ſome one caterpillar gave the name to all the reſt: as for the gilding itſelf, I take it to be nothing elſe but the ſcum of an evaporated juice between the ſkin of the caterpillar and the ſhell of the chryſalis, which laſt it covers."

The butterfly remains only a ſhort time in the chryſalis ſtate, the interval between the larva and perfect ſtate ſeldom exceeding ten, twenty, or thirty days. Theſe chryſalides are commonly ſuſpended by means of a few ſilken threads with the head downwards to the leaves or ſtems of trees, or againſt palings, &c. The chryſalis of the "common garden white" is a familiar example of this mode of ſuſpenſion, and of the brilliant appearance which this order of inſects aſſume in this ſtate.

The moth tribe remain much longer in the pupa form, and evince more care towards themſelves, in making choice of a ſituation adapted to this defenceleſs ſtage of life. The caterpillar having acquired its full ſize, ſeeks for a proper place in which it may remain in ſafety during this period, and having made choice of this, prepares for the important change. Some ſpin webs or cones in which they incloſe themſelves, others conceal themſelves in little cells which they form under ground, &c. Preparatory to the change the larva ceaſes to take any food, empties itſelf of all the excremental matter which the inteſtines contained, voiding at the ſame time the membrane which ſerves as a lining to theſe of the ſtomach. It generally perſeveres in a ſtate of reſt and inactivity for ſeveral days about this time. In proportion as the change into the pupa form approaches, the body is obſerved to extend and contract itſelf very often: the hinder part is firſt diſengaged from the ſkin, and after a while the ſkin is entirely caſt off.

The caterpillar, thus ſtripped from its ſkin, is called the pupa; the exterior covering gradually becomes hard, while the interior remains ſo ſoft that the ſlighteſt touch will decompoſe them. The exterior covering is at firſt covered with a viſcous fluid, which thickening and drying up, forms a thin ſkin or coat capable of reſiſting external injuries. Thoſe who are deſirous of tracing the various members of the future butterfly or moth in the pupa, ſhould examine it before this fluid dries up.

The length of time an inſect remains in the pupa form varies much in different ſpecies. As ſoon as the incloſed animal acquires ſufficient ſtrength to break the bonds of its confinement, it makes a powerful effort to eſcape. The moth frees itſelf from the pupa with greater facility than the pupa from the caterpillar; for the caſe of the pupa becomes ſo dry, when the moth is near the time of throwing off its covering, that it will crack and break to pieces if it be only gently preſſed between the fingers; and very few of the parts will be found, on examination, to adhere to the body. Hence, when the inſect has acquired a proper degree of ſolidity, it does not require any great exertion to ſplit the membrane which covers it: a ſmall degree of motion, or a little inflation of the body, is ſufficient for this purpoſe; theſe motions reiterated a few times enlarge the hole, and afford the moth room to eſcape from its confinement. The opening through which they paſs is always at the ſame part of the ſkin, a little above the trunk, between the wings and a ſmall piece which covers the head: the different fiſſures are generally made in the ſame direction. If the outer caſe be opened, it is eaſy to diſcover the efforts the inſect makes to emancipate itſelf from the ſhell. When the operation begins, there ſeems to be a violent agitation in the humours contained in the little animal; the fluids being driven with rapidity through all the veſſels, the limbs and various parts of the body are put in motion, and by repeated efforts it breaks through the brittle ſkin that envelopes it. Thoſe incloſed in cones or caſes, after burſting through the pupa covering, have another difficulty to overcome, that of piercing through the incloſure, which, in many inſtances, is of a ſtronger texture than the caſe of the pupa. For the accompliſhment of this, moſt inſects are provided with a liquor, which they diſcharge from the mouth upon that part of the cone through which they intend to eſcape, and this ſo moiſtens and weakens it, that after a ſhort time they force their paſſage through with ſome facility. Some inſects not provided with this fluid leave one end of their cone weaker than the reſt, and cloſe it only with a few threads, ſo that a ſlight effort of the head enables the inſect to burſt from its priſon.

The butterfly or moth, on emerging from the pupa, is moiſt and humid, the abdomen ſwollen, the antennæ bent down, and the wings crumpled, ſmall, and ſhapeleſs. Theſe parts gradually change and aſſume their deſtined form. The wings extend, and the fibres, which were at firſt flexible, become hard and rigid like bone. In proportion as the fibres loſe their flexibility, the fluids which circulate within them extend, and the wings ceaſe to act; ſo that if any extraneous circumſtance arreſts the progreſs of this fluid through the fibres, at the firſt inſtant of the moth's eſcape, the wings immediately become crippled, and never afterwards aſſume any other form. Theſe parts expand with ſuch rapidity, that the naked eye cannot entirely trace their developement. The wings, which at one inſtant are ſmall and like four little buds at the ſides of the thorax, in a few minutes after acquire their full ſize, ſo as to be nearly five times as large as they were before. Nor are they the wings only which are thus increaſed: all their ſpots and marks, heretofore ſo indiſtinct and ſmall as to be ſcarcely diſcernible, are proportionally extended, ſo that what before appeared as only ſo many unmeaning and confuſed points, become diſtinct and beautiful ornaments. When the wings are unfolded, the tongue rolled up, the mouth ſufficiently dried, and the different members ſtrengthened, it takes its flight. Moſt inſects, ſoon after they have attained their perfect ſtate, void an excrementitious ſubſtance, which ſome ſuppoſe to be the laſt they eject during life.

If the moth be now opened down the belly, and the fatty parts which fill it be removed, the groſs artery or heart will be viſible, and the contractions and dilatations, by which it puſhes forward the liquor it contains, may be eaſily obſerved. One of the moſt remarkable circumſtances is, that the circulation of this fluid in the moth is directly contrary to that which took place in the caterpillar. In this it moved from the tail to the head, whereas in the moth its current is from the head to the tail. The inteſtines are now formed in a more delicate manner, and ſuited to a purer aliment than that on which it ſubſiſted before its change into the pupa: the caterpillar devoured the groſſer parts of vegetables; the nutriment of the perfect inſect is the nectar of flowers. Many internal parts of the caterpillar diſappear in the pupa, and many that could not be before perceived are at length rendered viſible. And thus the creature, which heretofore crept on the earth, flies freely through the air, and, far from creating averſion by its foul appearance, now attracts attention by the elegance of its form and beauty of colour.

The induſtry of the caterpillar in the conſtruction of its cocoon, or other repoſitory, in which it paſſes the time deſtined for it to remain in the pupa ſtate, is highly worthy of remark. Some caterpillars, towards the time of their change, ſuſpend themſelves from the branch of a tree, with the head downward, and are transformed in this poſition. Many of the moth kind cover with threads that part of the branch from which it means to ſuſpend itſelf: it places theſe in different directions, and then covers them with other threads ſucceſſively, till the cone in which it is to become a pupa is finiſhed. The caterpillar hooks itſelf by the hinder feet to this hillock; and when it has found by ſeveral trials that it is ſtrongly fixed thereto, throws itſelf forward, letting the body fall with the head downwards. Soon after it is thus ſuſpended it bends the fore part of the body, which poſture it retains for ſome time; then ſtretching the body, again in a little time bending it, and ſo on, repeating this operation till it has formed a ſlit in the ſkin upon the back. Part of the pupa ſoon forces itſelf through this, and extends the ſlit as far as the laſt cruſtaceous feet: the pupa then forces upwards the ſkin, by means of its little hooks, and the motion of the body, till it has ſlipped it off to that part from which the caterpillar had ſuſpended itſelf.

The mode of ſuſpenſion adopted by ſome inſects is very different from that purſued by others. Some fix themſelves in an horizontal poſition, by means of a girdle, which they tie round the body, ſo as to ſupport the caterpillar, and yet leave it at full liberty to effect the changes: others ſuſpend themſelves in webs, in temporary habitations, formed by weaving together two or three leaves of the plant on which they feed, by means of ſilken threads. The induſtry of thoſe which ſpin cones or caſes, in which they incloſe themſelves, in order to prepare for their transformation, is very generally known from the familiar hiſtory of the common ſilk-worm, an inſect from which man derives the moſt eſſential benefits. In northern Europe theſe advantages are ſcarcely known, and are eſteemed valuable only in proportion as they contribute to the luxury of dreſs; becauſe our woollens are better ſuited to the viciſſitudes of the climates. But in a far more extenſive portion of the habitable globe, ſilk conſtitutes an article of the firſt neceſſity in uſeful clothing; and hence the labours of this induſtrious little creature become in the higheſt degree important and beneficial to the human race.

The ſilky tiſſues of this inſect are ſpun by the caterpillar, for the ſole purpoſe of enveloping and ſuſpending itſelf in ſecurity during its pupa ſtate. The ſubſtance of which the ſilk is formed is a fine yellow tranſparent gum, contained in two reſervoirs that wind about the inteſtines, and which, when unfolded, are about ten inches long: they terminate in two exceeding ſmall orifices near the mouth, through which the ſilk is drawn or ſpun to the degree of fineneſs which its occaſions may require. This apparatus has been compared to the inſtrument in uſe for drawing gold and ſilver into threads. Each thread proceeds from the two reſervoirs at the ſame time, but they are united as the thread forms; ſo that, if examined by the microſcope, it will be found to conſiſt of two cylinders or threads glued together, with a groove along the middle, and in which ſometimes even a ſeparation may be perceived.

When the ſilk-worm is near the time of change to the pupa, the reſervoirs of ſilk are full, and it is preſſed by its ſenſations to relieve itſelf from this incumbrance. Having made choice of a convenient ſituation, the operation of ſpinning commences. At firſt it throws out ſome looſe thread, which ſerves to ſupport the future ſuperſtructure: upon theſe it forms an oval of a looſe texture, conſiſting of what is called flos ſilk; and within this it forms a firm and more conſiſtent ball of ſilk. It is now incloſed within the circumference of the ſpheroid, the interior of which is the ſcene of its further operations: in this it is ſeen reſting on its hinder parts, and with its mouth and fore legs directing and faſtening the threads. Theſe threads are not directed in a regular circular form, but are ſpun in different ſpots, in an infinite number of zig-zag lines; ſo that, when wound off, it proceeds in a very irregular manner. This thread, when meaſured, has been found to be about three hundred yards long, and ſo fine that eight or ten are generally rolled off into one by the manufacturer. The ſilk-worm uſually employs about three days in finiſhing this cone; the inſide is generally ſmeared with a kind of gum, which is deſigned to keep out the rain. It next aſſumes the pupa form, in which it remains from fifteen to thirty days, in different climates, before the moth is produced. When the inſect intends breaking from the cocoon, it moiſtens one end of the cone, and by frequent motions of the head looſens the texture of the ſilk, ſo as to form a hole without breaking it. See Silk-Worm, *Phalæna Mori*.

From a ſeries of experiments made by Reaumur on the ſilk of this inſect and that of the ſpider, in order to aſcertain their comparative excellence, it was found that the thread would bear the weight of thirty-ſix grains, while that of the ſpider could not ſuſtain twelve grains, breaking under its weight. There are ſilks ſpun by other inſects, with which we are little acquainted, that in point of ſtrength far exceeds that of the common ſilk-worm. The popular opinion, that the ſilk worn in different parts of the world is the ſole produce of this ſpecies (phal. mori), is erroneous. This kind of ſilk is generally eſteemed for its peculiar beauty and delicacy of texture. There are others leſs coſtly, which, from their ſuperior ſtrength, are better adapted to common wear, and are for this reaſon in more general uſe in ſome parts of the globe. The ſilk obtained from the cocoons of the two ſpecies of bombyces paphia and cynthia are of this kind, as appears from an intereſting paper on theſe inſects by Dr. Roxborough, F.L.S., inſerted in the ſeventh volume of the Tranſactions of the Linnæan Society.

Theſe inſects bear the names of tuſſeh and arrindy ſilk-worms in India: both exceed the common ſilk-worm in ſize, the firſt eſpecially, which is one of the largeſt of the attaci family of bombyies, and the ſilk of which appears to be more valuable than that of the other kind.

The tuſſeh ſilk-worm is found in ſuch abundance over many parts of Bengal, and the adjoining provinces, as to have afforded the natives from time immemorial an ample ſupply of a moſt durable coarſe ſilk, commonly called tuſſeh ſilk, which is woven into a kind of cloth called tuſſeh doot'hies, much worn by the Bramins, and other ſects of Hindoos. This ſubſtance would no doubt be highly uſeful to the inhabitants of many parts of America, and the ſouth of Europe, where a cheap, light, cool, and durable dreſs, ſuch as this ſilk makes, 'is much wanted. The caterpillar, when full grown, is about four inches in length, and bulky in proportion; its colour green, with a lateral ſtripe of yellow edged with red. The plate in which the caterpillar is repreſented, if we miſtake not, is engraven from a drawing executed by an Indian artiſt, and muſt be received with ſome allowance for inaccuracy; but from this we may collect that it has a ſingle ſeries of yellow oval dots beneath the lateral line, (amounting to ſix or ſeven in number,) which are perhaps its ſpiracles; and theſe, in the deſcription, are denominated ſpecks of gold colour. When theſe are ready to ſpin, each connects, by means of the recent glutinous filament of which the caſe is made, two or three leaves of the jujube tree, the vegetable on which they feed. Theſe connected leaves form an exterior envelope, which ſerves as a baſis to ſpin the complete caſe or cocoon in; and "beſides this," ſays the writer, "the caſe is ſuſpended from a ſtrong branch of the tree in a wonderful manner by a thick, ſtrong, conſolidated cord, ſpun of the ſame materials from the bowels of the animal." It remains nine months in the pupa ſtate. The inſect, when produced, expands to the breadth of five or ſix inches, and thoſe of the female to eight inches.

There is another kind of wild ſilk-worm produced in the Burbhoom hills, which is ſaid to be more capable of being domeſticated; and a fourth ſort, a ſuppoſed variety of the tuſſeh-worm, in the hills near Bauglipore, the cocoon of which is ſmaller than that of either of the two firſt mentioned.

The arrindy ſilk-worm ſtill remains to be noticed. This is of a ſpecies altogether different from the former, and is the bombyx cynthia of entomologiſts. This inſect, known to the Hindoos by the name of arrindy in ſome parts, and in others arrundi, appears to be peculiar to the interior parts of Bengal; and it is preſumed, may be even confined to the two diſtricts Dinagepore and Rungpore, where the natives breed and rear it in a domeſtic ſtate, as they do the common ſilk-worm. The food of the caterpillar conſiſts entirely of the leaves of the common ricinus or palma chriſti, which plant is cultivated abundantly over every part of India, on account of the oil obtained from the ſeed. The Hindoos call this plant arrindy, and hence is derived the name of the inſect. The caterpillar, when full fed, is about three inches long; the colour pale green; and each ſegment verticillated with a few conic tubercles diſpoſed in a ſingle line. The cocoon is white or yellowiſh, of a very ſoft and delicate texture, about two inches long, and three in circumference, and pointed at each end. There is a wide diſtinction between this ſpecies and B. paphia, in the period it remains in the pupa form; this requiring at the utmoſt not above twenty days, inſtead of nine months, to complete its laſt transformation.

The filaments of which the cocoon is compoſed are ſo exceedingly delicate, that it is ſaid to be impracticable to wind off the ſilk: it is therefore ſpun like cotton. The cotton, thus manufactured, is wove into a coarſe kind of white cloth, of a ſeemingly looſe texture, but of incredible durability; the life of one perſon being ſeldom ſufficient to wear out a garment made of it, ſo that the piece deſcends from mother to daughter. Some of the Indians, however, have a method of ſpinning the ſilk of this ſpecies, and the proceſs is related as follows. Four or five of the cocoons are faſtened to a piece of wood, with ſomething heavy to make it ſpin round, while ſuſpended by the thread. When they let out a ſufficient quantity of the cocoons from their hand, it is twiſted by this piece of wood ſpinning round; and when well twiſted, it is wound round the wood, and another length let out of the hand. The cocoons are ſpun wet, but only with cold water. The cloth is woven in ſmall pieces in a loom: its uſes are for clothing for both men and women; it will conſtantly wear ten, fifteen, or twenty years. This ſilk muſt be always waſhed in cold water; for if put into boiling water, it will tear like old rotten cloth. Some manufacturers ſeem to be of opinion that ſhawls, and other ſilken articles of dreſs, equal in quality to any manufactured in India, could be fabricated with this material. There is reaſon to apprehend that this ſilk is highly valued in India; nor can we entertain the leaſt diſtruſt of its want of durability, ſince it is well known that the coverings of their palanquins are of this particular kind of ſilk.

On further inveſtigation and reſearch into the hiſtory of the larger ſpecies of the bombyx tribe, we are perſuaded others will be found to form cocoons or pupa ſpinnings, which, with proper attention and culture, may hereafter be productive of ſimilar advantages. We are not ignorant that in other parts of Aſia, and in America, there are many ſpecies that ſpin in the ſame manner an envelope round the pupa; and ſome of theſe at leaſt, we muſt ſuppoſe, capable of producing a ſilk of beauty and durability equal to ſome of thoſe in preſent uſe. We ſhould not be ſurpriſed to learn that bombyx atlas, the moſt conſiderable in magnitude of all the moth tribe, is expreſsly reared in China for the ſake of its ſilk. We ſuſpect this to be the truth. It would be deſirable alſo to aſcertain whether the cocoons of the ſpecies heſperus, cecropia, cytherea, promothea, and ſome others, could not be beneficially employed in the production of ſilk. Mr. Abbot, in his Inſects of North America, ſpeaks generally of ſome attempts being made to fabricate the ſilk of one or two of the larger moths of that country; the cloth prepared from which is repreſented as ſtrong and durable: but he expreſſes doubt how far the experiment might be uſeful, as the inſects which produce the ſilk are not abundant. This objection might eaſily, we ſhould imagine, be obviated by cultivation: inſects are highly prolific, and if they could be reared in what may be termed a domeſticated ſtate, could be produced in any numbers.

Among a variety of other curious information which this paper conveys, the following circumſtances appear ſo amuſing, and ſeem to reflect ſuch new light on the hiſtory of theſe uſeful inſects, that we cannot refrain repeating them. The cocoons of this inſect, bombyx paphia, feed on the leaves of a plant called byer by the Hindoos (rhamnus jujuba), and likewiſe on the plant they call aſſeen (terminalia alta glabra of Roxb.). They are annual, remaining nine months in the pupa ſtate, and three months in that of the egg and caterpillar. The ſpecies cannot be domeſticated, nor can the natives even retain any for ſeed. The hill people ſay, they go into jungles, and under the byer and aſſeen trees they find the excrement of the inſect; on which they examine the tree, and, on diſcovering the ſmall worms, they cut off branches of the tree ſufficient for their purpoſe, with the young brood on the branches. Theſe they carry to convenient ſituations near their houſes, and diſtribute the branches on the aſſeen tree, in proportion to the ſize of them; but they put none on the byer tree. The Parieahs, or hill people, guard the inſects night and day, while in the worm ſtate, to preſerve them from the crows and other birds by day, and from bats by night. As ſoon as the moth pierces the caſes, it eſcapes; nor do the people prevent this, as they have learnt by experience that it cannot be kept alive more than a few days, and that retaining it would not be attended with any advantage.

To wind off theſe cocoons, the natives put them into a ley made of plantain aſhes and water for about two hours; after which they take them out of the ley, and put them in their wet ſtate into an earthen pot: thoſe which are properly ſoftened are firſt applied to the reel, and ſo on as the cocoons become ſoft, for four or five days, till the whole are wound off. The implement uſed for taking off the thread is a ſmall common reel of four bars. The cocoons are laid in a ſmooth earthen diſh without water; the reel is turned by the right hand, whilſt the thread of four or five cocoons paſſes over the left thigh of the ſpinner, and he gives the thread a twiſt with his left hand upon his thigh. The thread is exceedingly apt to come off double and treble for ſeveral yards together, which is not regarded by the natives, as breaking off double threads would diminiſh the produce, and moreover would occaſion loſs of time: a very even thread, however, with care may be reeled off. The bughy ſilk-worm feeds indifferently on byer or aſſeen leaves.

The jarroo cocoon is the pupa ſpinning of an inſect cloſely allied to the preceding, but whether a diſtinct ſpecies or variety, from the knowledge we at preſent poſſeſs, ſeems difficult to determine. Theſe are called the jarroo cocoon, from being produced in January, the coldeſt month of the year; and the natives affirm, that they are different from the bughy. The jarroo will eat the byer leaf, if it cannot get the aſſeen; but will always prefer the latter, and will produce better cocoons when fed on it. The ſilk is duller in colour. The natives are able to retain part of the jarroo cocoons for ſeed. Theſe they hang out on the aſſeen trees, when the proper ſeaſon of the moth arrives. The males, when hatched, invariably fly away; but the females remain on the trees. Theſe are not impregnated by the males bred along with them, but in ten or twelve hours, or perhaps two or three days, a flight of males arrive, ſettle on the branches, and impregnate the females; and it is worthy of remark, that the hill people conſider it good or ill fortune, in proportion to the ſpeedy or tardy arrival of theſe male viſitors. The purpoſes of nature accompliſhed, the males expire, and the females live only long enough to depoſit the eggs in ſafety on the branches of the trees. Theſe males are ſuppoſed by the natives to come from a vaſt diſtance: it is affirmed even, that by marking the wings of a number of males, previouſly to letting them fly, their progreſs in queſt of the females has been traced to the diſtance of one hundred miles and upwards. This, though remarkable, is not more extraordinary or unworthy of credit than the circumſtance (if truly ſtated), that the males and females of the ſame brood never aſſociate together in any manner, when they enter the fly ſtate; the males regularly flying off in ſearch of another brood of females, and leaving thoſe of their own family to the embraces of another flight of males.

There is a caterpillar which forms its ſilken cone in the ſhape of a boat turned bottom upwards, whence it is called by Reaumur "coque en batteau." It conſiſts of two principal parts, each of which is framed by itſelf, and formed of an innumerable quantity of minute ſilk rings; in the fore part there is a projection, in which a ſmall crevice may be perceived, which ſerves when opened for the eſcape of the moth; the ſides are framed with ſo much art, that they open and ſhut as if framed with ſprings; ſo that the cone from which the fly has eſcaped appears as cloſe as that which is ſtill inhabited.

Thoſe caterpillars which do not ſpin a cone ſupply that want with various materials, which they form into a habitation to ſecure them from injury while in the pupa ſtate: ſome form a covering with leaves and branches tied or made faſt together, others connect the leaves with great regularity: many ſtrip themſelves of their hairs and form a mixture of hair and ſilk, others conſtruct a cone of ſand or earth, cementing the particles together with a kind of glue:

ſome gnaw the wood into powder, or like ſaw-duſt, and cement it together; and others make caſes in holes, which they form in the trunks of trees.

The period of their change into the chryſalis or pupa ſtate is very regular in moſt inſects, unleſs in ſeaſons peculiarly unfavourable. Some change in May, others in June, July, Auguſt, and September, and the time of emerging from the ſtate of pupa is fixed with no leſs preciſion. This is a fact well known to every practical entomologiſt. Some remain in the pupa ſtate only twelve or fifteen days, others twenty or thirty, and theſe are chiefly of the butterfly tribe. Thoſe of the moth kind are commonly much longer, ſome remaining in this ſtate only two or three months, others ſix, nine, or twelve, ſome two years, and others even it is known ſo long as three years. Lyonet has remarked, that the periods of change to the chryſalis ſtate is not ſo conſtant, but that a degree more or leſs will affect it. The ſame inſect, he ſays, which in the middle of ſummer would have acquired its utmoſt ſize in leſs than three weeks, will require as many months, and even much more if it comes forth at the end of the ſeaſon. And again, he obſerves, that ſuch a nymph or chryſalis which in ſummer will change into a winged inſect in fifteen days, will employ ſometimes ſix, ſeven, or eight months for the ſame purpoſe, merely from having gone into the chryſalis ſtate a few days later than thoſe which have changed ſo rapidly. That particular incidents may occaſionally juſtify theſe remarks of Lyonet, we ſhall not diſpute, but this can be only underſtood of ininſects hatched in ſeaſons of unuſual inclemency, or under circumſtances in the higheſt poſſible degree uncongenial to their transformations. Irregularities will ariſe from this cauſe. In general, however, the appearance of every ſpecies (whoſe hiſtory is once correctly aſcertained) whether in the larva, pupa, or winged ſtate, may be determined by the time of the year. Moſt inſects perform all their changes within the courſe of twelve months, and are found in their ſeveral ſtates at particular periods annually; others have two broods in the courſe of that time, and conſequently appear in the ſame ſtate at two different periods of the year.

Neuroptera.—Some of this order are ſemi-nymphs, as the libellulæ and ephemeræ, in which the rudiments or half-wings are developed, and which eat and purſue the ſame manners of life as the larva. Others are like the nymphs of the coleopterous order in appearance, and lie dormant in the ground, generally in caſes conſtructed of extraneous materials. The myrmelion forms a hollow ball of ſand for this purpoſe.

Hymenoptera.—In the pupa of the cynips the limbs are partially diſcloſed in its external figure, and it remains in the central cavity of the gall in which it lives during the ſtate of larva, while in the pupa form. The tenthredo forms a kind of exterior caſe or envelopement, within which it aſſumes the pupa form, and which in ſome kinds reſembles the texture of thin parchment. The pupa of the ſirex is quieſcent, and is uſually found lodged in timber: this has the limbs diſtinctly formed. The pupæ of the ichneumons are incloſed in oblong ſilken cones. Thoſe of the waſps and bees are well known. In the ants the limbs are diſtinct.

Diptera.—The pupæ of the tipulæ are uſually cylindrical like the larva, and quieſcent; many of the muſcæ appear of an elongated egg ſhape, without any ſegmental diviſions, and totally devoid of motion. The pupa of the culex is curiouſly incurvated and ovate, with reſpiratory tubes, through which it breathes; it is an inhabitant of the waters. The egg of the hippoboſcæ ſerves in lieu of a pupa, or in other terms the hippoboſcæ are oviparous, and have no pupa.

Aptera.—As the individuals of this order are produced with few exceptions in the perfect form from the egg, they have no pupa, at leaſt the common flea is the only inſtance to the contrary; this undergoes the uſual transformations from the egg to the perfect ſtate; its pupa reſembles that of ſome coleopterous inſects when magnified.

Imago: the final or perfect ſtate which all inſects aſſume after paſſing through the ſucceſſive changes from the egg, the larva, and pupa form; which latter it quits in the imago ſtate. This might, with more ſimplicity, be termed the winged ſtate, were it not that ſome inſects, after quitting the pupa, are apterous, or without wings. In the imago form the inſect is in every reſpect perfect in all its parts, and poſſeſſed of every function which nature has intended the ſpecies to enjoy.

Habitation of Inſects.

Inſects are of two kinds, aquatic and terreſtrial, and their habitation muſt be conſidered ſeparately.

Some live only in watery places, appearing occaſionally on the ſurface of that element, and which very rarely plunge themſelves in, or if they fall in, either riſe again immediately to the ſurface or periſh. Others live only in water, and cannot ſubſiſt out of it. Many, after having lived in the water while in the larva and pupa ſtate, come out afterwards with wings, and become entirely terreſtrial. Some undergo all their transformations in the water, and then become amphibious. Others again are born and grow in the water, but remain during the pupa ſtate on dry land, and after they attain their perfect form live equally in air and water. There are, laſtly, ſome who live at the ſame time occaſionally both in the water and on land, and which, after their transformation, ceaſe to be aquatic.

Among the inſects which remain on the ſuperficies of the water, are ſome ſpiders which run with great addreſs and agility, without moiſtening their feet or their body. There are aquatic cimices which ſwim or rather run on the water with great velocity, and by troops, as may be often ſeen on the ſurface of ſtill water. Some walk ſlowly on the ſurface. The gyrinus moves ſwiftly and in circles. The nepæ are of that kind which live only in the water, and cannot ſubſiſt out of it, or at leaſt can remain out of it only a ſhort time. The number of thoſe which, after having lived in the water, leave it when in a winged ſtate is very great: among theſe are the libellula, the ephemera, the phryganea, culex, tipula, and ſome other ſpecies of muſcæ; all theſe are of the aquatic kind, both in the larva and pupa ſtate, but when they have aſſumed their perfect form are entirely terreſtrial, and would be drowned therein. The kinds moſt ſtrictly amphibious are the water beetles, ſuch as the dytiſcus and hydrophilus; theſe remain in the water all day, but towards evening come upon the ground and fly about, plunging themſelves again into the water at the approach of ſun-riſe: the larvæ of theſe inſects are entirely aquatic; but when the time of their pupa ſtate arrives they deſcend into the earth, where they make a ſpherical caſe, thus becoming entirely terreſtrial, and in the perfect ſtate are amphibious.

Moſt inſects of theſe tribes prefer ſtagnant waters, others thoſe of a purer nature, and we have inſtances of certain inſects which inhabit, with perfect convenience, ſprings of a warm and mineral nature. At the baths of Abano, in the Venetian ſtates, is a ſpring of this deſcription, impregnated with ſulphur, in which ſmall water beetles are ſeen ſwiming about, and which die on being taken out and plunged into cold water.

Many inſects that live under the ſurface of the earth in the perfect ſtate crawl out occaſionally, as the mole cricket, and ſome of the aptera, as the julus and ſcolopendra; theſe are generally found in the earth under ſtones, or beneath rotten wood in damp ſituations. Some inſects remain under-ground part of their life, but quit that ſituation after their change, as in the coleoptera. A vaſt number of others live in animal ſubſtances of every kind. The habitation of ſome, as the myrmeleon formicarius, is curiouſly conſtructed in the ſands.

There is a ſpecies of ſpider found in Jamaica (aranea venatoria) which burrows in the earth like a rabbit; it is of a ſize very far ſurpaſſing the largeſt of the European ſpiders, and is not uncommon there. This creature forms a hole twelve or fifteen inches deep, of a cylindrical ſhape, rather more than an inch in diameter, and which it lines with a thick coat to prevent the earth from tumbling in. The aperture is cloſed with a kind of lid or door attached by a ſingle hinge, and which open outwardly, falling down and ſhutting the aperture by its own gravity. Into this the ſpider retires with its prey, and devours it in ſafety, as few inſects can penetrate into its cell. Theſe neſts or caſes form a complete habitation, ſhould the ſands in which they are conſtructed give way.

Inſects of the lepidopterous order are very rarely carnivorous; there are inſtances of this, but theſe are uncommon. Their food and that of many other inſects are of the vegetable kind, and their habitations are trees and plants. The oak and the willow among trees, and numbers of different plants among herbage, are the natural habitation of inſects in great abundance. Some live in the roots, others in the wood; in the leaves, and in galls formed therein; in flowers; in fruit; and in grain. Some caterpillars form a kind of hammock, in which they eat and go through their various changes; while others conſtruct a tent, under which they live till they have conſumed the ſurrounding herbs, when they leave their abodes and pitch their tents in another ſpot, where they can find abundance.
